Abstract

Static equilibrium configurations of continuum supported by surface tension are given by constant-mean-curvature (CMC) surfaces which are the critical points of a variational problem to extremize the area with keeping the volume fixed. The geometry of CMC surfaces and their properties such as stability are of special importance in differential geometry and a variety of physical science. In this paper, we examine the stability of CMC hypersurfaces in general dimensions possibly having boundaries on two parallel hyperplanes, by investigating the second variation of area functional. We reveal the stability of non-uniform liquid bridges or unduloids for the first time in all dimensions and all parameter (the ratio of the neck radius to bulge radius) regimes. The analysis is assisted by numerical computations.
1 Introduction

A static equilibrium configuration of continuum supported by surface tension is known to be well approximated by a constant-mean-curvature (CMC) surface, which extremizes the surface area for given volume and boundary conditions. CMC surfaces are used as
mathematical models of variety of continuum, such as liquid, stars, and nucleus, to play important roles in both mathematics and physics \[1, 2\].

One of fundamental problems on CMC surfaces is to find stable CMC surfaces which possibly have boundaries on given two parallel planes $\Pi_1$ and $\Pi_2$. Here, a CMC surface is said to be stable if the second variation of area for any volume-preserving variation is non-negative. Allowing no self-intersections of surface, it is shown that equilibrium surfaces contained in the region bounded by $\Pi_1$ and $\Pi_2$ are axially-symmetric CMC surfaces with the straight line perpendicular to $\Pi_i$ as its rotation axis, and they make contact angles $\pi/2$ with $\Pi_i$ ($i = 1, 2$). Hence these surfaces are spheres, hemispheres, parts of cylinders and unduloids \[3\]. Among them, only spheres, hemispheres, and thick cylinders are stable. Thin cylinders and unduloids are unstable CMC surfaces, \textit{i.e.}, they extremize the area but do not minimize it for given volume \[4, 5\]. The instability of thin cylinder is known as the Plateau-Rayleigh instability \[6, 7\] in fluid mechanics.

An interesting non-trivial aspect of the above problem is that the stability of unduloid depends on the dimension. Namely, a higher-dimensional counterpart of the unduloid, which we also call an unduloid simply, can be stable \[8, 9\]. While the unduloids in higher dimensions were numerically obtained and their geometric quantities were computed \[10, 11, 12\], their stability has not been clarified completely so far (see statements (i)–(iv) in Sec. \[3\] of the present paper for a correct description of known results). Therefore, in this paper, we comprehensively examine the stability of unduloids in all dimensions and parameter regimes by investigating the second variation of area. The results are summarized as statements (I)–(IV) in Sec. \[5\].

The geometric quantities of unduloid such as surface area, bulk volume, and mean curvature are obtained with the help of numerical integration. The stability is determined by the behaviors of these geometric quantities and stability criteria. We prepare the stability criteria valid in general dimensions, generalizing the results known in three dimensions.

Before starting analysis, let us mention that the higher-dimensional CMC hypersurfaces attract much attention in the study of general relativity, in particular, black holes. The black-hole counterparts of the cylinder and unduloid are called a uniform black string and a non-uniform black string, respectively, and they exhibit various similarities with their counterparts \[13, 14\]. Furthermore, the ‘surface’ of a black hole (\textit{i.e.}, event horizon) was recently shown to be indeed approximated by a timelike CMC hypersurface in a large-dimension limit \[15\]. We will return this point in Sec. \[5\].

The organization of this paper is as follows. We begin with calculating the variations of surface area and bulk volume for axially symmetric hypersurfaces in Sec. \[2\]. Then, an

\[\text{In this paper, we are concerned with only the stability of a half period of unduloid } \mathcal{U} \text{ (from a neck to the next bulge or from a bulge to the next neck) since } m \times \mathcal{U} \text{ (} m \geq 2 \text{) is always unstable. Note that if a half period of an unduloid is stable (resp. unstable) between two parallel hyperplanes in } \mathbb{R}^{n+2} \text{ (} n \in \mathbb{N} \text{), one period of the unduloid is stable (resp. unstable) in } \mathbb{R}^{n+1} \times S^1, \text{ and vice versa. This is proved in Appendix A.1.}\]
eigenvalue problem associated with the second variation of area is introduced in Sec. 2.2. In Sec. 3, the stability criteria for unduloids are presented in terms of the eigenvalues, mean curvature, and volume. The stability of unduloids is examined in Sec. 4 using the criteria prepared in the previous section. Section 5 is devoted to summary and discussions. The proofs of mathematical propositions and the method to compute geometric quantities of unduloids are presented in Appendices A and B, respectively.

2 Variation and eigenvalue problem

2.1 Area, volume, and their variations

We consider axially symmetric hypersurfaces in the closed domain of $\mathbb{R}^{n+2}$ ($n \in \mathbb{N}$) bounded by two hyperplanes $\Pi_1 := \{z = z_1\}$ and $\Pi_2 := \{z = z_2\}$. The local radius of a hypersurface is represented by height function $h(z)$ (see Fig. 1).

It is convenient to consider one-parameter family of height function $h(z, \epsilon)$, where $\epsilon$ is a variation parameter. Then, the surface area and bulk volume of the axially symmetric object between $z = z_1$ and $z = z_2$ are

$$ A = a_n \int_{z_1}^{z_2} \sqrt{1 + h_z(z, \epsilon)^2} h(z, \epsilon)^n dz, $$

(1)

$$ V = v_{n+1} \int_{z_1}^{z_2} h(z, \epsilon)^{n+1} dz. $$

(2)

Here, $a_n$ and $v_{n+1}$ are the volume of a unit $n$-sphere and that of a unit $(n + 1)$-ball, respectively, given by

$$ a_n = (n + 1)v_{n+1} = \frac{2\pi^{n+1}}{\Gamma(n+1)}.$$

(3)

A partial derivative is denoted by a subscript as $h_z := \partial_z h$ hereafter. The mean curvature of the hypersurface is

$$ H = \frac{1}{n + 1} \left[ \frac{h_{zz}}{(1 + h_z^2)^{3/2}} - \frac{n}{h\sqrt{1 + h_z^2}} \right].$$

(4)

For a cylinder, hemisphere, and unduloid, $H$ takes a negative value in the present convention.

---

[2] Our main subject is to judge the stability of a half period of unduloid. By using the Schwarz symmetrization, we see that it is sufficient to study only axially symmetric variations. Namely, if the second variation of area is nonnegative for all axially symmetric volume-preserving variations of unduloid, then such an unduloid is stable. See Lemma A.1 in Appendix A.2 for a more general statement.
The calculation of variations is equivalent to obtain the coefficients of the following expansion,

\[ X(\epsilon) = \sum_{\ell=0}^{\infty} \frac{X_{\ell}}{\ell!} \epsilon^\ell, \quad X = h, A, V, \text{ or } H. \] (5)

The coefficient of expansion is obtained by \( X_{\ell} = \partial_{\ell} X_{\epsilon=0} (\ell = 0, 1, 2, \cdots) \).

The first variations of area and volume are easily obtained in terms of \( h_0(z) \) and \( h_1(z) \),

\[ A_1 = -(n + 1)a_n \int_{z_1}^{z_2} H_0 h_0^2 h_1 dz + a_n \left[ \frac{h_0^2 h_0 z}{1 + h_0^2 z} h_1 \right]_{z_1}^{z_2}, \] (6)

\[ V_1 = a_n \int_{z_1}^{z_2} h_0^3 h_1 dz. \] (7)

From Eqs. (6) and (7), one sees that the hypersurface which is the surface of revolution of \( h_0 \) is an equilibrium configuration or a critical point if and only if the following conditions hold,

\[ H_0(z) = \text{const.}, \] (8)

\[ h_{0z}(z_1) = h_{0z}(z_2) = 0. \] (9)

Condition of CMC for the equilibrium configuration (8) corresponds to the Young-Laplace relation in fluid mechanics [10].

Now, let us focus on the volume-preserving variation (\( V_\epsilon \equiv 0 \)) of CMC hypersurface, for which Eqs. (8) and (9) hold. For such a variation, the first derivative of area can be written as

\[ A_\epsilon = A_\epsilon + (n + 1)H_0 V_\epsilon \] (10)

\[ = -(n + 1)a_n \int_{z_1}^{z_2} \left( H(z, \epsilon) - H_0 \right) h^n h_\epsilon dz + a_n \left[ \frac{h^n h_\epsilon h_\epsilon}{\sqrt{1 + h_\epsilon^2}} \right]_{z_1}^{z_2}. \] (11)

Then, the second derivative of area is

\[ A_{\epsilon\epsilon} = -(n + 1)a_n \int_{z_1}^{z_2} \left( H_\epsilon h^n h_\epsilon + n(H - H_0)h^{n-1}h_\epsilon^2 + (H - H_0)h^n h_{\epsilon\epsilon} \right) dz \]

\[ + a_n \left[ \left( \frac{h^n h_\epsilon h_\epsilon}{\sqrt{1 + h_\epsilon^2}} \right) \right]_{z_1}^{z_2}. \] (12)

Using Eqs. (8), (9) and (12), one obtains the second variation of area in terms of \( h_0, h_1, \) and \( H_1 \),

\[ A_2 = -(n + 1)a_n \int_{z_1}^{z_2} H_1(z) h_0^3 h_1 dz + a_n \left[ h_0^3 h_1 h_{1z} \right]_{z_1}^{z_2}. \] (13)

It is noted that \( A_2 \) is independent of \( h_2 \) due to the addition of term \((n + 1)H_0 V_\epsilon \) in Eq. (10).
Figure 1: A hypersurface in $\mathbb{R}^{n+2}$ axially symmetric along coordinate $z$. $h$ represents the radius of a $n$-sphere $S^n$ which is the intersection of the hypersurface and $z = \text{const.}$ hyperplane.

The first variation of mean curvature $H_1$ in Eq. (13) can be written as

$$H_1(z) = \frac{1}{(n+1)h_0^n} \mathcal{L} h_1,$$

by defining the following linear operator

$$\mathcal{L} := \frac{d}{dz} \left( \sigma(z) \frac{d}{dz} \right) + \frac{nh_0^{n-2}}{\sqrt{1 + h_0^2 z}},$$

$$\sigma(z) := \frac{h_0^n}{(1 + h_0^2 z)^{3/2}}.$$  \hspace{1cm} (15)

Therefore, $A_2$ is written in a simple form,

$$A_2 = -a_n \int_{z_1}^{z_2} h_1 \mathcal{L} h_1 dz + a_n [h_1 \sigma(z) h_{1z}]_{z_1}^{z_2}.$$  \hspace{1cm} (17)

### 2.2 Eigenvalue problem associated with second variation of area

An equilibrium is defined to be stable if the second variation is non-negative for all volume-preserving variations. This condition is equivalent to $A_2 \geq 0$ for all variations satisfying $V_1 = 0$.

From this viewpoint, let us consider the following eigenvalue problem associated with $A_2$.

$$\mathcal{L} \varphi_i(z) = -\lambda_i \varphi_i(z),$$

$$\varphi_{iz}(z_1) = \varphi_{iz}(z_2) = 0,$$

where $i = 1, 2, 3, \cdots$ labels the eigenvalue $\lambda_i$ and eigenfunction $\varphi_i(z)$. Since $\mathcal{L}$ is a Sturm-Liouville operator, it is shown that $\lambda_1 < \lambda_2 < \lambda_3 < \cdots$, and that $\varphi_i(z)$ has exactly $i - 1$ zeros in $(z_1, z_2)$. 

6
The general variation of height function is a linear combination of the eigenfunctions
\[ h_1(z) = \sum_{i=1}^{\infty} c_i \varphi_i(z), \quad c_i \in \mathbb{R}. \]
Then, \( A_2 \) and \( V_1 \) are written in terms of \( c_i \) and \( \lambda_i \),
\[
A_2 = a_n \sum_{i=1}^{\infty} c_i^2 \lambda_i, \quad (19)
\]
\[
V_1 = a_n \sum_{i=1}^{\infty} c_i \int_{z_1}^{z_2} h_0^n \varphi_i dz, \quad (20)
\]
where the orthonormality \( \int_{z_1}^{z_2} \varphi_i \varphi_j dz = \delta_{ij} \) is assumed.

From Eqs. (19) and (20), one sees that an equilibrium \( h_0 \) is stable when \( \lambda_1 \geq 0 \) since in such a case \( A_2 > 0 \) for all non-trivial (i.e., \( h_1 \neq 0 \)) volume-preserving variations satisfying \( V_1 = 0 \). One the other hand, one sees that an equilibrium is unstable when \( \lambda_2 \) is negative. Namely,
\[
\lambda_2 < 0 \implies \text{unstable} \quad (21)
\]
holds since in such a case \( A_2 < 0 \) for the volume-preserving variation given by
\[
c_1 = -\frac{\int_{z_1}^{z_2} h_0^n \varphi_2 dz}{\int_{z_1}^{z_2} h_0^n \varphi_1 dz} c_2, \quad c_2 \neq 0, \quad c_i = 0 \quad (i \geq 3). \quad (22)
\]

For a uniform cylinder \( h_0 \equiv r = \text{const.} \), Eq. (18) is
\[
\frac{d^2 \varphi_i}{dz^2} + \frac{nr^{n-2} + \lambda_i^{\text{cyl}}}{r^n} \varphi_i = 0. \quad (23)
\]
If one puts \( z_1 = 0, z_2 = L > 0 \), the eigenvalue of a cylinder \( \lambda_i^{\text{cyl}} \) is obtained by solving Eq. (24),
\[
\lambda_i^{\text{cyl}} = \left( \frac{(i-1)\pi r}{L} \right)^2 - n \quad r^{n-2}, \quad i = 1, 2, 3, \ldots. \quad (24)
\]
From Eq. (24), one can see that if
\[
r < r_c := \frac{\sqrt{nL}}{\pi}, \quad (25)
\]
\( \lambda_2^{\text{cyl}} < 0 \) holds and such a thin cylinder is unstable from criterion (21) (see also Refs. [17, 18] for a dynamical counterpart). More precisely, it is proved that the cylinder with radius \( r \) and length \( L \) is stable if and only if \( r \geq r_c \) holds (cf. [9]). We call the cylinder with critical radius \( r_c \) a critical cylinder. \( \lambda_2^{\text{cyl}} < 0 \) holds and such a thin cylinder is unstable from criterion (21) (see also Refs. [17, 18] for a dynamical counterpart). More precisely, it is proved that the cylinder with radius \( r \) and length \( L \) is stable if and only if \( r \geq r_c \) holds (cf. [9]). We call the cylinder with critical radius \( r_c \) a critical cylinder.

The sphere \( S^{n+1} \) and the hemisphere with a boundary in \( z = z_1 \) or \( z = z_2 \) are stable because \( S^{n+1} \) is the minimizer of area among all closed hypersurfaces enclosing the same volume.
Figure 2: Diagrams representing criterion (28). If the mean curvature of unduloid is (a) larger (resp. (b) smaller) than that of the critical cylinder $H(s) > H(0)$ (resp. $H(s) < H(0)$), $\lambda_2$ is negative (resp. positive). Note that $H$ takes negative values in the present convention.

3 Stability criteria of unduloids

It is convenient to introduce a quantity parameterizing the family of unduloids. As such a quantity, we adopt the non-uniformness parameter defined by

$$s := 1 - \frac{h_{\min}}{h_{\max}} \in (0, 1),$$

(26)

where $h_{\min}$ and $h_{\max}$ denote the radii of an unduloid at the neck and bulge, respectively. One can naturally assign $s = 0$ and $s = 1$ to the critical cylinder and the largest hemisphere, that fits the interval, respectively. In the rest of this paper, we denote the half period of unduloid itself, mean curvature, volume, and eigenvalue of such an unduloid by $U(s)$, $H(s)$, $V(s)$, and $\lambda_i(s)$, respectively.

For $U(s)$, one can show the negativity (resp. positivity) of $\lambda_1$ (resp. $\lambda_3$). Namely, the following holds,

$$\lambda_1(s) < 0 < \lambda_3(s), \quad \forall s \in (0, 1).$$

(27)

See Appendix A.3 for a proof.

In the rest of this section, we will introduce mathematical theories which play crucial roles in the stability analysis of Sec. 4. In Sec. 3.1 we see how to know the sign of $\lambda_2(s)$ from the behavior of $H(s)$. While $\lambda_2(s) < 0$ immediately implies the instability of $U(s)$ from (21), another criterion is needed to determine the stability of $U(s)$ when $\lambda_2(s) \geq 0$. Therefore, in Sec. 3.2 we see how the behavior of $H(s)$ and $V(s)$ determines the stability when $\lambda_2(s) \geq 0$.

\[\text{In this paper, we assume the continuity of } \lim_{s \to +0} X = X|_{s=0} \text{ and } \lim_{s \to -1-0} X = X|_{s=1} \text{ for } X = A, V \text{ and } H.\]
3.1 Sign of second eigenvalue $\lambda_2$

From Eq. (24), one can see that the second eigenvalue of cylinder $\lambda_2^{\text{cyl}}$ increases and changes its sign from negative to positive as radius $r$ increases. From the point where $\lambda_2(0) = 0$, two branches of unduloid $\lambda_2(s)$ emanate (see Fig. 2). For these branches of unduloid just bifurcated from the critical cylinder, the sign of $\lambda_2(s)$ is determined by the relative value of mean curvature to that of the critical cylinder. Namely, if the mean curvature of emanating unduloid $H(s)$ is larger (resp. smaller) than that of the critical cylinder $H(0)$, the second eigenvalue of unduloid $\lambda_2(s)$ is negative (resp. positive),

$$H(s) \gtrless H(0) \implies \lambda_2(s) \leq 0. \quad (28)$$

This statement is derived from Theorem A.2 in Appendix A.4. The criterion is visualized in Fig. 2. This criterion can be utilized to determine the sign of $\lambda_2(s)$ of $U(s)$ close to the cylinder $0 < s \ll 1$.

In order to know when $\lambda_2(s)$ changes its sign, the following criteria are quite useful.

$$H'(s) \neq 0 \text{ at } s \implies \lambda_2 \text{ does not change its sign at } s, \quad (29)$$

$$H' = 0 \& H'' \neq 0 \& V' \neq 0 \text{ at } s \implies \lambda_2 = 0 \& \lambda_2 \text{ changes its sign at } s. \quad (30)$$

Their proofs are presented in Appendix A.5. What criteria (29) and (30) mean is that, under the assumption that $H''(s) \neq 0$ and $V'(s) \neq 0$, $\lambda_2(s)$ changes its sign when $H'(s)$ does. Although the possibility that $\lambda_2(s)$ vanishes even when $H'(s) \neq 0$ is not excluded by (29), it can be proved that

$$H'(s) \neq 0 \implies \lambda_2(s) \neq 0. \quad (31)$$

See Prop. A.2 in Appendix A.6. Thus, once the sign of $\lambda_2(s)$ near $s = 0$ (the critical cylinder) is determined by (28), the sign of $\lambda_2$ in all range of $s$ is known by investigating $H''(s)$ and $V'(s)$ at zeros of $H'(s)$.

3.2 Criteria when $\lambda_2 \geq 0$

While $\lambda_2(s) < 0$ immediately implies that unduloid $U(s)$ is unstable from (24), another criteria are necessary to determine the stability of $U(s)$ when $\lambda_2(s) \geq 0$. From the criteria for the stability given by Lemma A.2 in Appendix A.2, we have the following observations.

When $\lambda_2(s) = H'(s) = 0$ and $V'(s) \neq 0$ hold, $U(s)$ is unstable. Namely, the following holds,

$$\lambda_2(s) = H'(s) = 0 \& V'(s) \neq 0 \implies \text{unstable}. \quad (32)$$

The half period of unduloid that has a neck at $z_1$ and one has a bulge at $z_1$ are distinguished in the current bifurcation theory, although their physical properties are identical.
When $\lambda_2(s) > 0$, the stability is related to the increasing and decreasing of mean curvature and volume. Namely, $U(s)$ with $\lambda_2(s) > 0$ is unstable (resp. stable) if $H'(s)V'(s)$ is negative (resp. non-negative).

$$\lambda_2(s) > 0 \quad \& \quad \begin{cases} H'(s)V'(s) < 0 \\ H'(s)V'(s) \geq 0 \end{cases} \implies \begin{cases} \text{unstable} \\ \text{stable} \end{cases}$$

We will utilize criteria (32) and (33) to determine the stability of $U(s)$ whose $\lambda_2(s)$ is non-negative.

### 3.3 Comment: No iteration is needed

In the next section, we numerically obtain the mean curvature and volume for each $U(s)$. Before starting such an analysis, let us see that obtaining $H(s)$, $V(s)$, and their derivatives numerically is a much simpler task than solving eigenvalue problem (18).

$H(s)$ and $V(s)$ can be computed by just obtaining the ‘background’ solution $h_0(z)$. $h_0(z)$ is obtained by solving $H_0(z) = \text{const.}$ with boundary conditions $h_{0z}(z_1) = h_{0z}(z_2) = 0$. At a first glance, this problem seems to be a two-boundary problem requiring an iterative integration. By reducing $H_0(z) = \text{const.}$, which is a second-order ODE (ordinary differential equation), to an equivalent potential problem (a first-order ODE) and introducing an appropriate parameterization, however, no iteration turns out to be needed and the geometric quantities of unduloids, $H(s)$ and $V(s)$, are obtained by just estimating several improper integrals numerically (see Appendix B).

On the other hand, the eigenvalue equation (18) is essentially a two-boundary problem requiring the iteration procedure as in the shooting method [19]. Furthermore, one has to numerically solve the “perturbation equation” (18) for $\psi_2(z)$ and $\lambda_2$ on the numerical background $h_0(z)$, which is a part of operator $L$ in Eq. (15).

Thus, it is stressed here that the stability criteria presented in Secs. 3.1 and 3.2 are not only easy to use but also enormously reduce the amount of numerical computations required in the analysis. This is nothing but the merit to adopt the geometric variational method throughout in our analysis, rather than ordinary mode-decomposition methods being the standard of stability analysis in physics.

### 4 Stability of unduloids in $\mathbb{R}^{n+2}$ ($n \in \mathbb{N}$)

What to do in order to examine the stability of all unduloids is to obtain height function $h_0(z)$ corresponding to the half period of unduloid by numerically integrating ODE $H_0(z) = \text{const.}$ with boundary conditions $h_{0z}(z_1) = h_{0z}(z_2) = 0$, while taking the dimension $n \in \mathbb{N}$ and non-uniformness $s \in (0, 1)$ as free parameters. Then, one can estimate the
mean curvature $H$ and volume $V$ as functions of $s$ for each $n$. Finally, utilizing stability criteria (31) and (28)–(33), one can determine the stability of every unduloid.

Note that height function $h_0(z)$ of unduloids in general dimensions and corresponding geometric quantities have been numerically obtained already in [10], but the stability of unduloids in general dimensions has not been known completely. The stability of half period of unduloid in $\mathbb{R}^{n+2}$ ($n \in \mathbb{N}$) between two parallel hyperplanes known so far are summarized in the following four statements [4, 5, 8, 9].

(i) For $n \geq 1$, if an unduloid is sufficiently close to a hemisphere, it is unstable.

(ii) For $1 \leq n \leq 6$, any unduloid is unstable.

(iii) For $7 \leq n \leq 9$ (resp. $n \geq 10$), if an unduloid is sufficiently close to a cylinder, it is unstable (resp. stable).

(iv) For $n \geq 8$, there exists an unduloid which is stable.

From the above statements, one can see that our understanding is incomplete. For example, it is not known if there exists a stable unduloid for $n = 7$. Even for $n \geq 8$, it is not known in which parameter regions the stable unduloid exists.

In the rest of this section, we will clarify the stability of unduloids in all dimensions and parameter regimes of $s$. According to the behaviors of geometric quantities, we classify the dimensions into four classes, A ($1 \leq n \leq 6$), B ($n = 7$), C ($8 \leq n \leq 9$), and D ($n \geq 10$), and examine the stability separately. Qualitative features of diagrams and stability structures are common in each class. The results in a final form are summarized as four statements (I)–(IV) in Sec. 5.

The characteristic area-volume diagrams of the unduloid, cylinder, and hemisphere are shown in Fig. 3. In addition, the numerical plots of $H'(s)$ and $V'(s)$, the derivatives of mean curvature and volume of unduloid $U(s)$ with respect to $s$, are presented also in Fig. 3.

The area in the area-volume diagram is normalized in such a way that the area of hemisphere remains unity in all range of volume. The volume is normalized in such a way that the volume of the largest hemisphere, which fits the interval $[z_1, z_2]$, is unity. In the plot of $H'(s)$ and $V'(s)$, $H'(s)$ and $V'(s)$ are normalized by $\lim_{s \to 1^-} |H'(s)|$ and $\lim_{s \to 1^-} |V'(s)|$, respectively.

5In fact, ODE $H_0(z) = \text{const.}$ can be reduced to an equivalent first-order ODE and the geometric quantities (area, volume, and mean curvature) of unduloids are written as improper integrals, which are functions of only $s$ (after fixing the period of unduloid) for each $n$. Therefore, what to do is to estimate such improper integrals accurately. See Appendix B for details.
Figure 3: Left panels: Area-volume diagrams of the cylinder (dashed black line), hemisphere (thick blue line), and unduloid (red dots with solid line) for \( n = 6, 7, 8, \) and 10, from the top to the bottom. Right panels: \( H'(s) \) (solid orange line) and \( V'(s) \) (dashed green line) of unduloid \( U(s) \) for \( n = 6, 7, 8, \) and 10 from the top to the bottom.
Table 1: The sign of $H'(s)$, $\lambda_2(s)$, and $V'(s)$ and the stability of unduloid $U(s)$ in $\mathbb{R}^{n+2}$ as function of non-uniformness parameter $s \in (0,1)$ in Class A, B, C, and D.

| Class A |  |
|---------|---|
| $s$     |  |
| $H'(s)$ | + |
| $\lambda_2(s)$ | − |
| $V'(s)$ | + |
| stability | unstable |

| Class B |  |
|---------|---|
| $s$     | $s_0$ | $s_1$ | $s_2$ | $s_3$ |
| $H'(s)$ | + | 0 | − | 0 | + |
| $\lambda_2(s)$ | − | 0 | + | 0 | − |
| $V'(s)$ | + | 0 | − | 0 | + |
| stability | unstable | stable | unstable |

| Class C |  |
|---------|---|
| $s$     | $s_1$ | $s_2$ | $s_3$ |
| $H'(s)$ | − | 0 | + |
| $\lambda_2(s)$ | + | 0 | − |
| $V'(s)$ | + | 0 | − | 0 | + |
| stability | unstable | stable | unstable |

| Class D |  |
|---------|---|
| $s$     | $s_2$ | $s_3$ |
| $H'(s)$ | − | 0 | + |
| $\lambda_2(s)$ | + | 0 | − |
| $V'(s)$ | − | 0 | + |
| stability | stable | unstable |

4.1 Class A: $1 \leq n \leq 6$

It is characteristic to this class that any unduloid has larger area than the cylinder and hemisphere with the same volume, and the area-volume curve of unduloid has no cusp.

From Fig. 3 one can see that $H'(s) > 0$, $\forall s \in (0,1)$. Therefore, the sign of $\lambda_2(s)$ is definite in all range of $s$ from criteria [29] and [31]. From the fact that $H'(s) > 0$ in the
vicinity of \( s = 0 \), \( H(s) > H(0) \) holds for the unduloid just bifurcated from the critical cylinder, which implies \( \lambda_2(s) < 0 \) near \( s = 0 \) with criterion (28) (see also Fig. 2). Thus, \( \lambda_2(s) < 0 \) holds \( \forall s \in (0, 1) \), with which (21) implies all unduloids are unstable in this class. This is consistent with the known result in the literature, i.e., statement (ii).

### 4.2 Class B: \( n = 7 \)

It is characteristic to this class that the area-volume curve of unduloid has two cusps to form a swallowtail shape. We observe that both \( H'(s) \) and \( V'(s) \) have two simple zeros, which we denote by \( s_k \) \( (k = 0, 1, 2, 3) \) as

\[
H'(s_0) = V'(s_1) = V'(s_2) = H'(s_3) = 0, \quad 0 < s_0 < s_1 < s_2 < s_3 < 1. \tag{34}
\]

From the behavior of \( H'(s) \), one knows that \( \lambda_2(s) \) vanishes and changes its sign only at \( s = s_0 \) and \( s = s_3 \) with criteria (29)–(31). From this fact and the behavior of \( H'(s) \) with criterion (28), one can see that \( \lambda_2(s) < 0 \) (resp. \( \lambda_2(s) \geq 0 \)) for \( s \in (0, s_0) \cup (s_3, 1) \) (resp. \( s \in [s_0, s_3] \)). Therefore, \( \mathcal{U}(s) \) for \( s \in (0, s_0) \cup (s_3, 1) \) is unstable with criterion (21). Since \( \lambda_2(s) \geq 0 \) for \( s \in [s_0, s_3] \), we have to see also the behavior of \( V'(s) \) in order to use criteria (32) and (33). From Fig. 3 \( V'(s) \) vanishes at neither \( s = s_0 \) nor \( s = s_3 \), with which (32) implies that \( \mathcal{U}(s_0) \) and \( \mathcal{U}(s_3) \) are unstable. Since \( H'(s)V'(s) < 0 \) (resp. \( H'(s)V'(s) \geq 0 \)), \( \mathcal{U}(s) \) is unstable (resp. stable) for \( s \in (s_0, s_1) \cup (s_2, s_3) \) (resp. \( s \in [s_1, s_2] \)).

The stability of unduloid depending on \( s \) is summarized in Table 1 and values of \( s_k \) \( (k = 0, 1, 2, 3) \) numerically obtained are presented in Table 2.

As mentioned before, the existence of stable unduloid for \( n = 7 \) has not been known. Thus, the stable unduloid for \( s \in [s_1, s_2] \) is found for the first time in this paper.

### 4.3 Class C: \( 8 \leq n \leq 9 \)

In this class the area-volume curve of unduloid has two cusps as in Class B. \( V'(s) \) has two simple zeros, but \( H'(s) \) has only one simple zero. Taking into account the correspondence to Class B, we denote these zeros as follow.

\[
V'(s_1) = V'(s_2) = H'(s_3) = 0, \quad 0 < s_1 < s_2 < s_3 < 1. \tag{35}
\]

From the behavior of \( H'(s) \), one sees that \( \lambda_2(s) \) changes its sign only at \( s = s_3 \) with criteria (29)–(31). From this fact and the behavior of \( H'(s) \) with criterion (28), one can see that \( \lambda_2(s) \geq 0 \) (resp. \( \lambda_2(s) < 0 \)) for \( s \in (0, s_3) \) (resp. \( s \in (s_3, 1) \)). Therefore, \( \mathcal{U}(s) \) is unstable for \( s \in (s_3, 1) \) with criterion (21). Since \( \lambda_2(s) \geq 0 \) for \( s \in (0, s_3) \), one has to see the behavior of \( V'(s) \) to use criteria (32) and (33). Since \( V'(s_3) \neq 0 \), \( \mathcal{U}(s_3) \) is unstable with (32). Since \( H'(s)V'(s) < 0 \) (resp. \( H'(s)V'(s) \geq 0 \)), \( \mathcal{U}(s) \) is unstable (resp. stable) for \( s \in (0, s_1) \cup (s_2, s_3) \) (resp. \( s \in [s_1, s_2] \)) with (33). These results are consistent with the known results in the literature, i.e., statements (i)–(iv).
4.4 Class D: \( n \geq 10 \)

In this class the area-volume curve of unduloid has only one cusp. Both \( H'(s) \) and \( V'(s) \) have a simple zero. Taking into account the correspondence to the other classes, we denote the zeros as follow.

\[
V'(s_2) = H'(s_3) = 0, \quad 0 < s_2 < s_3 < 1. \tag{36}
\]

From the behavior of \( H'(s) \) and criteria (28)–(31), one sees that \( \lambda_2(s) \) changes its sign only at \( s = s_3 \) and \( \lambda_2(s) \geq 0 \) (resp. \( \lambda_2(s) < 0 \)) for \( s \in (0, s_3] \) (resp. \( s \in (s_3, 1) \)). Therefore, \( U(s) \) for \( s \in (s_3, 1) \) is unstable with (21). Since \( \lambda_2(s) \geq 0 \) for \( s \in (0, s_3] \), we have to see the behavior of \( V'(s) \) in order to use criteria (32) and (33). Since \( V'(s_3) \neq 0 \), \( U(s_3) \) is unstable with (32). Since \( H'(s)V'(s) < 0 \) (resp. \( H'(s)V'(s) \geq 0 \)), \( U(s) \) is unstable (resp. stable) for \( s \in (s_2, s_3) \) (resp. \( s \in (0, s_2) \)) with criterion (33).

5 Summary and discussions

The equilibrium configuration of continuum supported by only surface tension (i.e., ignoring external gravity and self-gravity) is well approximated by the CMC (constant-mean-curvature) surface that is the critical point of the variational problem extremizing the surface area with keeping the volume fixed. We have investigated the stability of CMC hypersurfaces in \( \mathbb{R}^{n+2} \) (\( n \in \mathbb{N} \)) that possibly have boundaries on two parallel hyperplanes, by examining if the CMC hypersurfaces not only extremize but also minimize the surface area with keeping the volume fixed. In particular, we have focused on the stability of non-uniform liquid bridges, as known as the Delaunay unduloids \[3\], of which stability had been known partially \[4, 5, 8, 9\] as statements (i)–(iv) presented in Sec. 4.

We have revealed the stability of unduloids for all \( n \in \mathbb{N} \) and for all range of non-uniformness parameter \( s \in (0, 1) \), defined by Eq. (26). After obtaining mean curvature \( H \) and volume \( V \) of unduloids as functions of \( s \) numerically, the stability of unduloids was determined using their derivatives and stability criteria (21) and (28)–(33) presented in Sec. 3.

Although the behaviors of both \( H(s) \) and \( V(s) \) have played the central roles in our stability analysis, an interesting point is that the regions of \( s \) where the unduloid is stable (resp. unstable) completely coincide with those where \( V(s) \) is non-increasing (resp. increasing) for any \( n \) (see Table 1). Therefore, the bottom line of the stability analysis is summarized without mentioning \( H(s) \) as follows.

Let \( s \in (0, 1) \) be the non-uniformness parameter of a half period of unduloid between two parallel hyperplanes in \( \mathbb{R}^{n+2} \) (\( n \in \mathbb{N} \)) defined by Eq. (26). The half period of unduloid with parameter \( s \) and its bulk \((n + 2)\)-volume are denoted by \( U(s) \) and \( V(s) \), respectively (the distance between the two hyperplanes is fixed). Then, the following (I)–(IV) hold.
Table 2: Values of $s_k$ ($k = 0, 1, 2, 3$) for several $n$. There exists no $s_k$ ($k = 0, 1, 2, 3$) in Class A ($1 \leq n \leq 6$). The existence of $s_k$ ($k = 0, 1, 2, 3$) is the same in each class.

| $n$ | 7   | 8   | 9   | 10  | 11  |
|-----|-----|-----|-----|-----|-----|
| $s_0$ | 0.437 | n/a | n/a | n/a | n/a |
| $s_1$ | 0.507 | 0.275 03 | 0.093 270 8 | n/a | n/a |
| $s_2$ | 0.665 | 0.765 33 | 0.803 961 7 | 0.828 991 30 | 0.847 468 517 |
| $s_3$ | 0.671 | 0.765 41 | 0.803 966 2 | 0.828 991 56 | 0.847 468 533 |

(I) For any $n \geq 1$, $U(s)$ is stable (resp. unstable) if and only if $V'(s) \leq 0$ (resp. $V'(s) > 0$).

(II) If $1 \leq n \leq 6$, then $U(s)$ is unstable for any $s \in (0, 1)$.

(III) If $7 \leq n \leq 9$, there exist $s_1$ and $s_2$ such that $V'(s_1) = V'(s_2) = 0$ and $0 < s_1 < s_2 < 1$. For $s \in [s_1, s_2]$ (resp. $s \in (0, s_1) \cup (s_2, 1)$), $U(s)$ is stable (resp. unstable).

(IV) If $n \geq 10$, there exists $s_2$ such that $V'(s_2) = 0$ and $0 < s_2 < 1$. For $s \in (0, s_2)$ (resp. $s \in (s_2, 1)$), $U(s)$ is stable (resp. unstable).

The values of $s_1$ and $s_2$ are presented in Table 2 with other characteristic values, $s_0$ and $s_3$ (see Eqs. (34), (35), and (36) for the definitions).

We have not paid much attention to the behavior of hemispheres and cylinders since their stability structure is completely understood as mentioned in Sec. 2.2. Nevertheless, let us have a look at them here, from which one can see the inevitability of the region where $V'(s) \leq 0$ for $n \geq 8$. As can be seen in Fig. 3, the area-volume curves of hemisphere and cylinder intersect for $n \leq 7$, but not for $n \geq 8$. A crucial reason of this is that the ratio of the volume of critical cylinder $V(0)$ to that of the largest hemisphere (i.e., the hemisphere which fits the interval $[z_1, z_2]$) $V(1)$, given by

$$
\frac{V(0)}{V(1)} = \frac{v_n r^{n+1} L}{L_{r=r_c}} = \begin{cases} 
\frac{(n+2)n+1}{2n\pi} \frac{(n-1)!}{\left[\left(\frac{n+1}{2}\right)!\right]^2} & (n: \text{odd}) \\
\frac{2n+1}{2n\pi} \frac{(n+1)(n+2)n+1}{\left[\left(\frac{n+1}{2}\right)!\right]^2} & (n: \text{even})
\end{cases}
$$

(37)

increases with $n$ and becomes larger than the unity for $n \geq 8$ (see Table 3). Namely, for $n \geq 8$ the branch of unduloid emanating from the critical cylinder at $s = 0$ must have region where the volume decreases to reach the largest hemisphere at $s = 1$. Although dimension $n = 7$, at and above which the stable unduloid exists, is different from this critical number of dimension $n = 8$ by one, their closeness is clearly not a coincidence.
Table 3: The ratio of the volume of critical cylinder $V(0)$ to the volume of largest hemisphere $V(1)$, that fits the interval $[z_1, z_2]$. This quantity exceeds the unity at $n = 8$.

| $n$ | 1   | 6   | 7   | 8   | 9   | 10  | 11  |
|-----|-----|-----|-----|-----|-----|-----|-----|
| $V(0)/V(1)$ | 0.152 | ⋮ | 0.408 | 0.623 | 1.005 | 1.707 | 3.033 | 5.621 |

Incidentally, let us point out that the area-volume curve deforms ‘continuously’ if $n$ changes continuously. As $n$ increases from 1, the ‘swallowtail’ (two cusps) of the area-volume curve appears at $n \simeq 7$. As $n$ increases further, the swallowtail becomes large. In other words, $s_1$ decreases to approach 0 and $s_2$ increases to approach 1. Indeed, $s_1$ decreases as $n$ increases to disappear finally at $n \simeq 10$. As far as we know, $s_2$ continues to increase but does not disappear for arbitrarily large $n \gg 1$, which is consistent with statement (i). If one treats $n$ as a continuous parameter and examines the stability for non-integer $n$, which seems to bring no technical problem, the behaviors of area-volume curve and stability structure expected and described above would be observed.

In this paper, the stability of unduloids was determined by the behaviors of $H(s)$ and $V(s)$, which were obtained by numerical integration. Therefore, the correctness of conclusion is based on that of these numerical computations. It is noted that one needs highly accurate computation to show that $s_2 < s_3$ holds ($s_2$ and $s_3$ are defined as the zeros of $V'(s)$ and $H'(s)$, respectively) for $n \geq 8$. For example, $s_3/s_2 - 1 \simeq +5.6 \times 10^{-6}$ for $n = 9$ by our computation, and this quantity seems to decrease further as $n$ increases. Nevertheless, we assumed that $s_2 < s_3$ continues to hold for arbitrarily large $n$, otherwise our conclusion on the stability might be different from those presented in the text. Therefore, any analytic method or alternative numerical methods that guarantee accuracy will be helpful to confirm the results in this paper.

Related to the results of this paper, one of the most interesting problems would be to investigate the implications to dynamical problems. While this was partially worked by one of the present authors in [18] using the surface-diffusion equation [20, 21], there are many things to do in this direction.

We remark that the stability of black strings qualitatively exhibits a similar dependence on the dimension. Suppose a $D$-dimensional vacuum spacetime ($D \geq 5$) whose one spatial direction is compactified on a circle $S^1$. Then, there exist non-uniform black strings of which horizon topology is $S^{D-3} \times S^1$. The stability of such black strings has been examined using the thermodynamic criterion, and argued as follows [14]. If $5 \leq D \leq 11$, all non-uniform black strings are unstable. If $12 \leq D \leq 13$, there exists a critical non-uniformness below (resp. above) which the non-uniform black strings are unstable (resp. stable). If $D \geq 14$, all black strings are stable. We are not so surprised at the similarity of stability
between these black objects and CMC hypersurfaces since it was shown that the event horizon of a black hole is approximated by a CMC hypersurface in the large-dimension limit \[15\]. Nevertheless, it is still interesting to pursue the similarity from various points of view such as the fluid/gravity correspondence \[22, 23\].

Acknowledgments

The authors would like to thank the organizers and participants of “The 20th Workshop on Singularities, Spacetimes, and Related Physics,” held at Kyushu University (January 12–14th, 2019), especially N. Tanahashi, for useful discussions and comments. U.M. thanks K.-i. Maeda for collaboration on related works and R. Emparan for useful discussion during the long-term workshop on “Holographic vistas on Gravity and Strings” (May 11th–July 18th 2014) held at YITP, Kyoto University. A Mathematical propositions and their proofs

A.1 Stability of a half period and one period of unduloid

Here, we prove

**Proposition A.1** If a half period of an unduloid is stable (resp. unstable) between two parallel hyperplanes in \(\mathbb{R}^{n+2} (n \in \mathbb{N})\), one period of the unduloid is stable (resp. unstable) in \(\mathbb{R}^{n+1} \times S^1\), and vice versa.

**Proof.** Let \(X\) be a half period of an unduloid \(\mathcal{U}\) with the \(z\)-axis as its axis of revolution that is generated by a curve

\[(z, h(z)), \ h(z) > 0, \quad 0 \leq z \leq z_2.\] (38)

This implies that \(X\) is perpendicular to the hyperplanes \(\Pi_0 = \{z = 0\}, \Pi_2 = \{z = z_2\}\).

Without loss of generality, we may assume that \(z = 0, z = z_2\) corresponds to the bulge, the neck of \(\mathcal{U}\), respectively. Denote by \(Y\) the one period of \(\mathcal{U}\) that is generated by

\[(z, h(z)), \ h(z) > 0, \quad -z_2 \leq z \leq z_2.\] (39)

Assume that \(X\) is unstable. Then, there exists a volume-preserving variation \(X(\epsilon)\) of \(X\) such that

\[
\left. \frac{d^2 A(X(\epsilon))}{d\epsilon^2} \right|_{\epsilon=0} < 0
\]
holds. By reflection with respect to $\Pi_0$, we get a volume-preserving variation $Y(\epsilon)$ of $Y$ that satisfies
\[
\left. \frac{d^2 A(Y(\epsilon))}{d\epsilon^2} \right|_{\epsilon=0} = 2 \left. \frac{d^2 A(X(\epsilon))}{d\epsilon^2} \right|_{\epsilon=0} < 0,
\]
which implies that $Y$ is also unstable.

Assume now that $Y$ is unstable. Then, there exists a volume-preserving variation $Y(\epsilon)$ of $Y$ such that
\[
\left. \frac{d^2 A(Y(\epsilon))}{d\epsilon^2} \right|_{\epsilon=0} < 0
\]
holds. Let $\hat{Y}(\epsilon)$ be the Steiner symmetrization of $Y(\epsilon)$ with respect to $\Pi_0$, that is, $\hat{Y}(\epsilon)$ is a hypersurface defined by the conditions (i) and (ii) below. Note that we consider only hypersurfaces close to $Y$. Set $\Pi_{-2} = \{ z = -z_2 \}$. Denote by $G(\epsilon)$, $\hat{G}(\epsilon)$ the closed domains bounded by $Y(\epsilon) \cup \Pi_{-2} \cup \Pi_2$, $\hat{Y}(\epsilon) \cup \Pi_{-2} \cup \Pi_2$, respectively. For each point $P \in \Pi_0$, denote by $L_P$ the straight line that passes $P$ and is perpendicular to $\Pi_0$. Define two straight line segments as $\hat{\Gamma}(\epsilon) := L_P \cap \hat{G}(\epsilon)$, $\Gamma(\epsilon) := L_P \cap G(\epsilon)$.

(i) The lengths of $\hat{\Gamma}(\epsilon)$ and $\Gamma(\epsilon)$ are the same, $(\forall P, \epsilon)$.

(ii) The middle point of $\hat{\Gamma}(\epsilon)$ lies on $\Pi_0$, $(\forall \epsilon)$.

Then, it is well-known that
\begin{enumerate}
  \item[(a)] $V(G(\epsilon)) = V(\hat{G}(\epsilon))$ holds, $(\forall \epsilon)$,
  \item[(b)] $A(Y(\epsilon)) \geq A(\hat{Y}(\epsilon))$ holds, $(\forall \epsilon)$
\end{enumerate}
hold (cf. [24, Note A]). Therefore, $\hat{Y}(\epsilon)$ is a volume-preserving variation of $Y$ such that it is symmetric with respect to $\Pi_0$ and such that
\[
\left. \frac{d^2 A(\hat{Y}(\epsilon))}{d\epsilon^2} \right|_{\epsilon=0} \leq \left. \frac{d^2 A(Y(\epsilon))}{d\epsilon^2} \right|_{\epsilon=0} < 0
\]
holds. The restriction $\hat{X}(\epsilon)$ of $\hat{Y}(\epsilon)$ to $\{ 0 \leq z \leq z_2 \}$ is a volume-preserving variation of $X$ such that
\[
\left. \frac{d^2 A(\hat{X}(\epsilon))}{d\epsilon^2} \right|_{\epsilon=0} = \frac{1}{2} \left. \frac{d^2 A(\hat{Y}(\epsilon))}{d\epsilon^2} \right|_{\epsilon=0} < 0
\]
holds. Hence $X$ is unstable. \hfill \Box

### A.2 Stability criteria for axially symmetric equilibrium hypersurfaces

Let
\[ (z, h(z)), \quad h(z) > 0, \quad z_1 \leq z \leq z_2 \]
define an axially-symmetric equilibrium hypersurface $X$ with the $z$-axis as its axis of revolution, that is, $X$ is a part of either a cylinder or an unduloid with generating curve \([40]\) and it is perpendicular to the hyperplanes $\Pi_i = \{ z = z_i \}$, $(i = 1, 2)$. Then, one can show the following lemma.
Lemma A.1  \( X \) is stable if and only if \( X \) is stable for axially-symmetric variations.

Proof. Assume that \( X \) is unstable. Then, there exists a volume-preserving variation \( X(\epsilon) \) of \( X \) such that

\[
\frac{d^2A(X(\epsilon))}{d\epsilon^2} \bigg|_{\epsilon=0} < 0
\]

holds. Let \( \hat{X}(\epsilon) \) be the Schwarz symmetrization of \( X(\epsilon) \), that is \( \hat{X}(\epsilon) \) is an axially-symmetric hypersurface defined by the conditions (i) and (ii) below. Note that we may assume that \( X(\epsilon) \) does not have self-intersection and it is contained in the closed domain bounded by \( \Pi_1, \Pi_2 \), because we consider only hypersurfaces close to \( X \). Denote by \( G(\epsilon) \), \( \hat{G}(\epsilon) \) the closed domains bounded by \( X(\epsilon) \cup \Pi_1 \cup \Pi_2 \), \( \hat{X}(\epsilon) \cup \Pi_1 \cup \Pi_2 \), respectively. For each hyperplane \( \Pi_c := \{ z = c \}, (z_1 \leq c \leq z_2) \), set \( \hat{D}(\epsilon) := \Pi_c \cap \hat{G}(\epsilon) \), then it is a round \((n+1)\)-ball.

(i) \( \hat{D}(\epsilon) \) has the same \((n+1)\)-volume as \( D(\epsilon) := \Pi_c \cap G(\epsilon), (\forall c, \epsilon) \).

(ii) The center of \( \hat{D}(\epsilon) \) lies on the \( z \)-axis.

Then, it is well-known that

(a) \( V(G(\epsilon)) = V(\hat{G}(\epsilon)) \) holds, \((\forall \epsilon)\),

(b) \( A(X(\epsilon)) \geq A(\hat{X}(\epsilon)) \) holds, \((\forall \epsilon)\)

hold (cf. [24, Note A]). Therefore, \( \hat{X}(\epsilon) \) is a volume-preserving axially-symmetric variation of \( X \) such that

\[
\frac{d^2A(\hat{X}(\epsilon))}{d\epsilon^2} \bigg|_{\epsilon=0} < 0
\]

holds. Hence \( X \) is unstable for axially-symmetric variations.

The opposite direction is trivial. \( \square \)

Now we give two criteria of the stability for axially-symmetric equilibrium hypersurfaces. The first criterion (Lemma A.2) will be proved by using the second criterion (Lemma A.3) at the end of this subsection.

Lemma A.2 (First stability criterion) Assume that \( X(s) \) is a one-parameter smooth family of axially-symmetric equilibrium hypersurfaces generated by the curves

\[
(z, h(z, s)), \ h(z, s) > 0, \ z_1 \leq z \leq z_2,
\]

that is, \( X(s) \) are half periods of unduloids, and we assume that \( s \) is the parameter defined by \([27]\). Denote by \( H(s), V(s) \) the mean curvature, the enclosed \((n+2)\)-dimensional volume of \( X(s) \), respectively. Denote by \( \lambda_i(s) \) the \( i \)-th eigenvalue of the eigenvalue problem \([18]\) for \( X(s) \).

(I) If \( \lambda_1(s) \geq 0 \), then \( X(s) \) is stable.

(II) If \( \lambda_1(s) < 0 < \lambda_2(s) \), then the following (II-1)' and (II-2)' hold.

(II-1)' If \( H'(s)V'(s) \geq 0 \), then \( X(s) \) is stable.

(II-2)' If \( H'(s)V'(s) < 0 \), then \( X(s) \) is unstable.

20
(III) If \( \lambda_2(s) = 0 \), then the following (III-a) and (III-b) hold:

(III-a) Assume that \( H'(s) = 0 \) holds. If \( V'(s) \neq 0 \), then \( X(s) \) is unstable.

(III-b) Assume that \( H'(s) \neq 0 \) holds.

(III-b1) If \( H'(s)V'(s) \geq 0 \), then \( X(s) \) is stable.

(III-b2) If \( H'(s)V'(s) < 0 \), then \( X(s) \) is unstable.

(IV) If \( \lambda_2(s) < 0 \), then \( X(s) \) is unstable.

Remark A.1 In (III-a) in the above theorem, we assumed \( H'(s) = 0 \) and \( V'(s) \neq 0 \). If \( \lambda_2(s) = 0 \), \( H'(s) = 0 \) and \( V'(s) = 0 \), then all of the assumptions in (III-B) of Lemma A.3 are satisfied (see the proof of Lemma A.2). And hence, there exists such a function \( u \) indicated there and (III-B1), (III-B2) hold.

In view of Lemma A.1, the following lemma is proved by a modification of the proof of Theorem 1.3 in [25].

Lemma A.3 (Second stability criterion) Let \( X \) be an axially-symmetric equilibrium hypersurface generated by the curve

\[
(z, h(z)), \ h(z) > 0, \quad z_1 \leq z \leq z_2.
\]  

(42)

(I) If \( \lambda_1 \geq 0 \), then \( X \) is stable.

(II) If \( \lambda_1 < \lambda_2 \), then there exists a uniquely determined \( C^\infty \) function \( u : [z_1, z_2] \to \mathbb{R} \) which satisfies \( Lu = h^n \) and \( u'(z_1) = u'(z_2) = 0 \), and the following statements hold.

(II-1) If \( \int_{z_1}^{z_2} uh^n \, dz \geq 0 \), then \( X \) is stable.

(II-2) If \( \int_{z_1}^{z_2} uh^n \, dz < 0 \), then \( X \) is unstable.

(III) If \( \lambda_1 = 0 = \lambda_2 \), then the following statements hold:

(III-A) If there exists a \( \lambda_2 \)-eigenfunction \( e \) which satisfies \( \int_{z_1}^{z_2} eh^n \, dz \neq 0 \), then \( X \) is unstable.

(III-B) If \( \int_{z_1}^{z_2} eh^n \, dz = 0 \) for any \( \lambda_2 \)-eigenfunction \( e \), then there exists a uniquely determined \( C^\infty \) function \( u : [z_1, z_2] \to \mathbb{R} \) which satisfies \( Lu = h^n \), \( u'(z_1) = u'(z_2) = 0 \), and \( \int_{z_1}^{z_2} euh^n \, dz = 0 \) holds for any \( \lambda_2 \)-eigenfunction \( e \). And the following statements hold:

(III-B1) If \( \int_{z_1}^{z_2} uh^n \, dz \geq 0 \), then \( X \) is stable.

(III-B2) If \( \int_{z_1}^{z_2} uh^n \, dz < 0 \), then \( X \) is unstable.

(IV) If \( \lambda_2 < 0 \), then \( X \) is unstable.

The following observation will be used to prove Lemma A.2.
Lemma A.4 If $X(s)$ defined by (41) are half periods of unduloids and $s$ is the parameter defined by (26), then for any fixed $s$,

$$h_s(z, s) \neq 0$$

holds for all $z \in [z_1, z_2]$, where $h_s = \partial h / \partial s$.

Proof. Set

$$\rho := 1 - s.$$  \hfill (44)

It is sufficient to prove that for any fixed $\rho$,

$$h_\rho(z, \rho) \neq 0$$

holds for all $z \in [z_1, z_2]$.

Now we may assume that

$$\rho = \frac{h(z_1, \rho)}{h(z_2, \rho)}.$$  \hfill (46)

holds. Differentiating the both sides of (46) in $\rho$, we obtain

$$1 = \frac{h_\rho(z_1, \rho)h(z_2, \rho) - h(z_1, \rho)h_\rho(z_2, \rho)}{(h(z_2, \rho))^2}.$$  \hfill (47)

This implies that

$$h_\rho(z, \rho) = 0, \quad \forall z \in [z_1, z_2]$$  \hfill (48)

never occur.  \hfill \Box

Proof of Lemma A.2 (I) and (IV) are the same as those in Lemma A.3. So we will prove (II) and (III). As Eq. (14), one can show that

$$\mathcal{L}h_s = (n + 1)h^n H'(s).$$  \hfill (49)

Note that $H'(s)$ depends only on $s$.

First, we prove (II). Since $h_s \neq 0$ (Lemma A.4), and since zero is not an eigenvalue of (15), (49) implies $H'(s) \neq 0$. Hence, the function $u$ given in (II) of Lemma A.3 satisfies

$$u = \frac{h_s}{(n + 1)H'(s)}.$$  \hfill (50)

From Eq. (2), the following holds (changing variable from $\epsilon$ to $s$),

$$V'(s) = a_n \int_{z_1}^{z_2} h^n h_s dz.$$  \hfill (51)
Equation (50) with (51) gives
\[ \int_{z_1}^{z_2} u h^n dz = \frac{V'(s)}{(n+1) a_n H'(s)}, \tag{52} \]
which shows that (II) in Lemma A.2 is equivalent to (II) in Lemma A.3.

Next, we prove (III). Let \( e \) be an eigenfunction belonging to \( \lambda_2 = 0 \). Then,
\[ \int_{z_1}^{z_2} e \mathcal{L} h_s dz = \int_{z_1}^{z_2} h_s \mathcal{L} e \ dz = 0. \tag{53} \]
On the other hand, using (49), we have
\[ \int_{z_1}^{z_2} e \mathcal{L} h_s dz = (n+1) H'(s) \int_{z_1}^{z_2} e h^n \ dz. \tag{54} \]
Equation (53) combined with Eq. (54) gives
\[ H'(s) \int_{z_1}^{z_2} e h^n \ dz = 0. \tag{55} \]

First, assume that \( H'(s) = 0 \) holds. Then, since \( h_s \neq 0 \) (Lemma A.4), Eq. (49) implies that \( h_s \) is an eigenfunction belonging to \( \lambda_2 = 0 \). Since each eigenspace is one-dimensional,
\[ h_s = ce, \quad \exists c \in \mathbb{R} \setminus \{0\}. \tag{56} \]
Hence,
\[ V'(s) = a_n \int_{z_1}^{z_2} h_s h^n \ dz = c a_n \int_{z_1}^{z_2} e h^n \ dz. \tag{57} \]
Therefore, \( V'(s) \neq 0 \) is equivalent to \( \int_{z_1}^{z_2} e h^n \ dz \neq 0 \). From (III-A) in Lemma A.3 \( X(s) \) is unstable. This gives (III-a).

Lastly, we prove (III-b). Assume that \( H'(s) \neq 0 \) holds. From (55), there holds
\[ \int_{z_1}^{z_2} e h^n \ dz = 0. \tag{58} \]
Take the function \( u \) that is uniquely defined in (III-B) of Lemma A.3. Using (49), \( h_s \) is written as
\[ h_s = (n + 1) H'(s) u + be, \quad \exists b \in \mathbb{R}. \tag{59} \]
Then,
\[ V'(s) = a_n \int_{z_1}^{z_2} h_s h^n \ dz = (n + 1) a_n H'(s) \int_{z_1}^{z_2} u h^n \ dz \tag{60} \]
holds, which gives
\[ \int_{z_1}^{z_2} u h^n \ dz = \frac{V'(s)}{(n+1) a_n H'(s)}. \tag{61} \]
Hence, from (III-B) of Lemma A.3 we obtain (III-b). \( \square \)
A.3 Negativity (resp. positivity) of the first (resp. third) eigenvalue for unduloids

In addition to eigenvalue problem \([15]\), we consider also the following eigenvalue problem with Dirichlet boundary condition:

\[
\mathcal{L}\psi_i(z) = -\lambda_i \psi_i(z), \quad z_1 \leq z \leq z_2, \\
\psi_i(z_1) = \psi_i(z_2) = 0,
\]

and denote its \(i\)-th eigenvalue by \(\lambda_i^0[z_1, z_2] = \lambda_i^0\). Then, it is well-known that \(\lambda_1^0 < \lambda_2^0 < \cdots\) and

\[
\lambda_i < \lambda_i^0, \quad \forall i \in \mathbb{N}
\]

hold. Also recall that, since \(\mathcal{L}\) is a Sturm-Liouville operator, each of \(\varphi_i(z)\) and \(\psi_i(z)\) has exactly \(i - 1\) zeros in \((z_1, z_2)\). Recall that Eq. \([14]\) holds and consider the parallel translation

\[
\mathcal{U}(\epsilon) : (z + \epsilon, h(z)), \quad z_1 \leq z \leq z_2
\]

of the unduloid

\[
\mathcal{U} : (z, h(z)), \quad z_1 \leq z \leq z_2.
\]

Then, the mean curvature \(H(\epsilon)\) is the same as the mean curvature \(H_0\) of \(\mathcal{U}\). \(\mathcal{U}(\epsilon)\) can be represented as

\[
\mathcal{U}(\epsilon) : (z, h(z) - \epsilon), \quad z_1 + \epsilon \leq z \leq z_2 + \epsilon.
\]

Hence, we have from \([14]\) that

\[
0 = \mathcal{L}h_1 = \mathcal{L}(-h_z) = -\mathcal{L}(h_z).
\]

Since \(\mathcal{U}\) is a half period of an unduloid,

\[
h_z(z_1) = h_z(z_2) = 0
\]

holds and we may assume that \(h_z > 0\) on \(z_1 < z < z_2\). Hence, \(h_z\) is an eigenfunction of \([62]\) and the corresponding eigenvalue zero is the first eigenvalue \(\lambda_1^0\). Hence, by \([63]\),

\[
\lambda_1 < \lambda_1^0 = 0
\]

holds. Next, we assume that

\[
\lambda_3 \leq 0
\]

holds. Then, eigenfunction \(\varphi_3(z)\) has exactly two zeros \(\zeta_1, \zeta_2\), \((\zeta_1 < \zeta_2)\), in \((z_1, z_2)\). Hence, by the monotonicity of the eigenvalues of the problem \([62]\) with respect to the domain, we have

\[
0 = \lambda_1^0[z_1, z_2] < \lambda_1^0[\zeta_1, \zeta_2] = 0,
\]

which is a contradiction. Hence, \(\lambda_3\) must be positive. \(\square\)
A.4 Existence of bifurcation and estimate of eigenvalue in bifurcation branch

Assume that $I \subset \mathbb{R}$ is a non-empty open interval, and
\[(z, h(z, \epsilon)), \ h(z, \epsilon) > 0, \ z_1 \leq z \leq z_2, \ \epsilon \in I \subset \mathbb{R}\]
defines a smooth one-parameter family of axially-symmetric equilibrium hypersurfaces $\{X(\epsilon)\}_{\epsilon \in I}$, that is, each $X(\epsilon)$ is a part of either a cylinder or an unduloid and it is perpendicular to the hyperplanes $\Pi_i = \{z = z_i\}$, $(i = 1, 2)$, and $X(\epsilon)$ is of $C^\infty$ in $\epsilon$.

Denote by $H(\epsilon)$ the mean curvature of $X(\epsilon)$. Denote by $\lambda_i(X(\epsilon))$ the $i$-th eigenvalue of the problem (18) for $X(\epsilon)$.

Now we define the concept “bifurcation instant”.

**Definition A.1** For $\epsilon \in I$, we say that $\epsilon$ is a bifurcation instant for the family $\{X(\epsilon)\}_{\epsilon \in I}$ if there exists a sequence $\{\epsilon_k\}_{k \in \mathbb{N}}$ in $I$ and a sequence $\{Y_k\}_{k \in \mathbb{N}}$ such that:

(i) $\epsilon_k \to \epsilon$ as $k \to \infty$.

(ii) Each $Y_k$ is an axially-symmetric equilibrium hypersurface that is defined by
\[(z, h_k(z)), \ h_k(z) > 0, \ z_1 \leq z \leq z_2,\]
and the mean curvature of $Y_k$ is equal to $H(\epsilon_k)$ for all $k$.

(iii) $h_k(z) \to h(z, \epsilon)$, $(z_1 \leq z \leq z_2)$, as $k \to \infty$.

(iv) $h_k(\epsilon) \neq h(\epsilon, \epsilon)$ for all $\epsilon \in I$ and $k \in \mathbb{N}$.

In other words, $\epsilon$ is a bifurcation instant for the family $\{X(\epsilon)\}_{\epsilon \in I}$ if $X(\epsilon)$ is an accumulation of equilibrium hypersurfaces that are not congruent to any of the hypersurface of the family $\{X(\epsilon)\}_{\epsilon \in I}$.

**Remark A.2** The following Theorems A.1, A.2 are proved by modifications of the proofs of Theorems 1.1, 6.4 in [26], respectively.

**Theorem A.1 (Existence of bifurcation)** For simplicity, we assume that $I = (-\epsilon_0, \epsilon_0) \subset \mathbb{R}$ holds. Assume

(i) $H'(0) \neq 0$.

(ii) $\lambda_i(X(0)) = 0$ for some $i \in \mathbb{N}$, and $e$ is an eigenfunction belonging to zero eigenvalue.

Then, $\int_{\Sigma} e \ d\Sigma = 0$, and there exists a differentiable map $(-\epsilon_1, \epsilon_1) \ni \epsilon \mapsto \lambda(\epsilon) \in \mathbb{R}$, with $0 < \epsilon_1 \leq \epsilon_0$, such that $\lambda(0) = 0$, $\lambda(\epsilon)$ is a simple eigenvalue of the eigenvalue problem (18) for $X(\epsilon)$, and there is no other eigenvalue of (18) near 0.

Assume further that $\lambda'(0) \neq 0$ holds. Then there is a unique smooth bifurcation branch $\{Y(t)\}_t$ of axially-symmetric equilibrium hypersurfaces issuing at $X(0)$. More precisely,
let \( E^\perp \) be the orthogonal complement of \( E := \{ae \mid a \in \mathbb{R}\} \) in \( C^\infty([z_1, z_2]) \) with respect to the \( L^2 \) inner product. Then, there exist an open interval \( \hat{I} \subset \mathbb{R} \) with \( 0 \in \hat{I} \), and \( C^1 \) functions \( \zeta: \hat{I} \rightarrow E^\perp \) and \( \epsilon: \hat{I} \rightarrow \mathbb{R} \), such that \( \epsilon(0) = 0 \), \( \zeta(0) = 0 \), and \( Y(t) \) is given by \( \hat{h}(z, t) := h(z, \epsilon(t)) + t\epsilon(z) + t\zeta(t)(z) \) with mean curvature \( \hat{H}(t) := H(\epsilon(t)) \).

Moreover, the hypersurfaces \( \{X(\epsilon) : \epsilon \in \hat{I}\} \) and \( \{Y(t) : t \in \hat{I}\} \) are pairwise distinct except for \( X(0) = Y(0) \).

**Theorem A.2** Under the assumptions of Theorem A.1, denote by \( \{Y(s)\}_{s \in \hat{I}} \) the bifurcating branch of axially-symmetric equilibrium hypersurfaces given in Theorem A.1. Let \( \hat{H}(s) \) be the mean curvature of \( Y(s) \), and \( \mu(s) \) the eigenvalue for the Jacobi operator \( \mathcal{L}_{Y(s)} \) which was defined by (12). We may assume that \( \hat{H}'(0) > 0 \) holds, by changing the parameter \( t \) to \(-t\) if necessary.

Then, the following statements are true.

(i) If \( \hat{H}'(s) = 0 \) for \( s \) near \( 0 \) (i.e., if \( \hat{H} \) is locally constant), then \( \mu(s) = 0 \) for \( s \) near \( 0 \);

(ii) If \( \hat{H}'(s) \neq 0 \) for \( |s| > 0 \) small, then, for a sufficiently small \( s_0 > 0 \), on each interval \([-s_0, 0]\) and \((0, s_0] \), \( \mu(s) > 0 \) if \( \lambda'(0)s\hat{H}'(s) < 0 \), and \( \mu(s) < 0 \) if \( \lambda'(0)s\hat{H}'(s) > 0 \). In particular, supercritical and subcritical pitchfork bifurcations correspond to the cases where \( s\hat{H}'(s) \) does not change sign at \( s = 0 \) (cf. Fig. 2), and transcritical bifurcation occurs when \( s\hat{H}'(s) \) changes sign at \( s = 0 \).

**A.5 Correspondence of sign change between the eigenvalue and mean-curvature derivative**

In this section we prove (29) and (30).

Assume that \( \{X(\epsilon)\}_{\epsilon \in \hat{I}} \) satisfies the same assumption as that in Section A.4. Denote by \( H(\epsilon) \) the mean curvature of \( X(\epsilon) \), and by \( V(\epsilon) \) the enclosed \((n+2)\)-dimensional volume by \( X(\epsilon) \). Denote by \( \lambda_i(\epsilon) \) the \( i \)-th eigenvalue of the problem (18) for \( X(\epsilon) \).

The criterion (29) is proved as follows.

**Proof of the criterion (29).** Assume that \( X(s_0) \) is a part of an unduloid. Assume also that \( H' \neq 0 \) holds at \( s_0 \). If \( \lambda_2 \) changes its sign at \( s_0 \), we can see that \( s_0 \) is a bifurcation instant by the same way of the proof of Proposition 2.14 in [27] which is an application of [28] Theorem 2.1. However, in our variational problem, there is no bifurcation from any unduloid \( X(\epsilon) \), which is a contradiction. Therefore, \( \lambda_2 \) does not change its sign at \( s_0 \), which proves the criterion (29).

The criterion (30) is given by the following Lemma A.5.
Lemma A.5 Assume that, for a fixed \( \epsilon \), \( H'(\epsilon) = 0 \), \( H''(\epsilon) \neq 0 \), \( V'(\epsilon) \neq 0 \), and \( \lambda_j(\epsilon) = 0 \) for some \( j \in \mathbb{N} \). Then, there exists a non-zero real number \( \alpha \) such that

\[
\alpha^2 \lambda'_j(\epsilon) = -(n+1)H''(\epsilon)V'(\epsilon)
\]  

holds. Particularly, \( \lambda_j \) changes its sign at \( \epsilon \).

Proof. The formula (2.8) in [29] is about a functional \( F : \mathcal{H} \times \mathbb{R} \to \mathbb{R} \), where \( \mathcal{H} \) is a real Hilbert space. In our case, let \( \mathcal{H} \) be the space of real-valued \( C^\infty \) functions on the interval \([z_1, z_2] \subset \mathbb{R}\) with inner product

\[
\langle f, g \rangle := \int_{z_1}^{z_2} f(z)g(z)h(z, \epsilon)^n \, dz.
\]

For any axially-symmetric (not necessarily equilibrium) hypersurface \( X_h \) generated by

\[
(z, h(z)), \ h(z) > 0, \ z_1 \leq z \leq z_2,
\]  

set

\[
F(h, a) := A(X_h) - aV(X_h),
\]

and we define another parameter \( H \) as

\[
-a := (n+1)H.
\]

Then, the equation (67) is equivalent to the formula (2.8) in [29]. \( \square \)

A.6 Equivalence of vanishment between the eigenvalue and mean-curvature derivative

Proposition A.2 Let \( X(s) \) be a one-parameter smooth family of half periods of unduloids with mean curvature \( H(s) \) generated by the curves

\[
(z, h(z), s), \ h(z, s) > 0, \ 0 \leq z \leq z_2, \ s \in (s_0 - \delta, s_0 + \delta), \ \delta > 0
\]  

with parameter \( s \) defined by (26). Then \( H'(s_0) = 0 \) if and only if \( \lambda_2(s_0) = 0 \) holds.

Proof. We prove the following (i), (ii) one by one.

(i) \( H'(s_0) = 0 \) \( \Rightarrow \) \( \lambda_2(s_0) = 0 \)

(ii) \( \lambda_2(s_0) = 0 \) \( \Rightarrow \) \( H'(s_0) = 0 \)

First, we prove (i). From Eq. (49) and Lemma A.4 if \( H'(s_0) = 0 \), then 0 is an eigenvalue. This with (27) implies that \( \lambda_2(s_0) = 0 \) holds.

Next, we prove (ii). Let the mean curvature of \( X(s_0) \) be \( H_0 \). Then, we have a one-parameter smooth family \( \{ \hat{X}(s) \} \) with \( \hat{X}(s_0) = X(s_0) \) of half period of unduloids with mean curvature \( H_0 \) generated by the curves

\[
(z, \hat{h}(z), s), \ \hat{h}(z, s) > 0, \ 0 \leq z \leq \zeta(s), \ s \in (s_0 - \delta', s_0 + \delta'), \ \delta' > 0.
\]
Note \( \hat{h}(\ast, s_0) = h(\ast, s_0) \), and we denote it by \( h_0 \).

Now, for a half period of an unduloid generated by the curve
\[
(z, h(z)), \quad h(z) > 0, \quad 0 \leq z \leq \zeta,
\]
denote by \( H[h] \) its mean curvature. Consider the equation
\[
H[\hat{h}(\ast, s)] = H_0.
\]
Then we have, using Eq. (49),
\[
\mathcal{L}_{\hat{h}_s} \bigg|_{s=s_0} = h_0^0 (n+1) \frac{\partial H[\hat{h}(\ast, s)]}{\partial s} \bigg|_{s=s_0} = 0.
\]
Since \( \hat{X}(s) \) is a suitable homothety of \( X(s) \), there exists a smooth positive function \( c(s) \) of \( s \) such that
\[
(c(s)z, \hat{h}(c(s)z, s)) = c(s)(z, h(z, s)), \quad c(s_0) = 1
\]
holds. Hence we have
\[
\hat{h}(c(s)z, s) = c(s)h(z, s),
\]
(74)
\[
c'(s)\hat{h}_z(c(s)z, s) + \hat{h}_s(c(s)z, s) = c'(s)h(z, s) + c(s)h_s(z, s).
\]
(75)
Since \( c(s_0) = 1 \), Eq. (75) gives
\[
c'(s_0)\hat{h}_z(z, s_0) + \hat{h}_s(z, s_0) = c'(s_0)h(z, s_0) + h_s(z, s_0),
\]
(76)
that is
\[
c'(s_0)(h_0)_z + \hat{h}_s(z, s_0) = c'(s_0)h_0 + h_s(z, s_0).
\]
(77)
Differentiating Eq. (74) with respect to \( z \) and setting \( z = 0 \), we have
\[
\hat{h}_{sz}(0, s_0) = -c'(s_0)h_{zz}(0, s_0) + c'(s_0)h_z(0, s_0) + h_{sz}(0, s_0).
\]
(78)
On the other hand, because \( \hat{h}(z, s) = \hat{h}(-z, s) \), we have
\[
\hat{h}_s(z, s) = \hat{h}_s(-z, s), \quad \hat{h}_{sz}(z, s) = -\hat{h}_{sz}(-z, s),
\]
(79)
which imply
\[
\hat{h}_{sz}(0, s) = 0.
\]
(80)
Assume now that \( \lambda_2(s_0) = 0 \) holds. Then, from Eqs. (73) and (80), by choosing a suitable eigenfunction \( e \) belonging to zero, \( \hat{h}_s(z, s_0) \) and \( e \) satisfy the same second order ODE, and their values and their first derivatives at \( z = 0 \) coincide. Hence, by the uniqueness of solutions of second order ODE, they coincide for all \( z \), and hence \( \hat{h}_s(z, s_0) \) is an eigenfunction belonging to zero. This implies
\[
\hat{h}_{sz}(z_2, s) = 0.
\]
(81)
Similarly, from \( h(z, s) = h(-z, s) \) and \( h(z_2 + z, s) = h(z_2 - z, s) \), we have

\[
h_z(0, s) = 0, \quad h_{sz}(0, s) = 0, \quad h_z(z_2, s) = 0, \quad h_{sz}(z_2, s) = 0.
\]

These facts with (78) give

\[
0 = -c'(s_0)h_{zz}(0, s_0).
\]  

(82)

However, \( h_{zz}(0, s_0) = 0 \) does not occur, which will be proved at the end of this section (Lemma A.6). Hence \( c'(s_0) = 0 \) holds. In this case, from Eq. (77), we have

\[
\hat{h}_s(z, s_0) = h_s(z, s_0).
\]  

(83)

Therefore, \( h_s(z, s_0) \) is an eigenfunction belonging to zero, and hence \( H'(s_0) = 0 \) holds. □

**Lemma A.6** Assume that \( X(s) \) satisfies the same assumption as that in Proposition A.2. Then, \( h_z(0, s) = 0 \) and \( h_{zz}(0, s) \neq 0 \) hold.

**Proof.** We assume that \( z = 0 \) corresponds to a bulge of \( X(s) \). In the case where \( z = 0 \) corresponds to a neck of \( X(s) \), a similar proof works.

Recall Eq. (4), which is equivalent to

\[
H(h^{n+1})_z = -\left(h^n(1 + h_z^2)^{-1/2}\right)_z.
\]  

(84)

Hence, we have, with an integration constant \( a \),

\[
Hh^{n+1} = -h^n(1 + h_z^2)^{-1/2} + a.
\]  

(85)

This \( a \) gives a one parameter family of unduloids with mean curvature \( H \). Set

\[
h_{\text{max}}(s) := h(0, s).
\]

Then, because \( h_z = 0 \) at the bulge, we have

\[
a = Hh_{\text{max}}^{n+1} + h_{\text{max}}^n.
\]  

(86)

Note that for the cylinder,

\[
h_{\text{max}}(\text{cylinder}) = \frac{-n}{(n + 1)H},
\]  

(87)

and hence

\[
a(\text{cylinder}) = \frac{n^n}{(n + 1)^{n+1}|H|^n}.
\]  

(88)

Regard \( a \) a function of \( h_{\text{max}} \), and differentiate the both sides of (86) with respect to \( h_{\text{max}} \) to get

\[
a' = H(n + 1)h_{\text{max}}^n + nh_{\text{max}}^{n-1} = \{(n + 1)Hh_{\text{max}} + n\}h_{\text{max}}^{n-1}.
\]  

(89)
Since
\[ h_{\text{max}} \leq h_{\text{max}}(\text{cylinder}) = \frac{-n}{(n + 1)H}, \]
we have
\[ a' \geq 0. \]
Hence,
\[ a \leq \frac{n^n}{(n + 1)^{n+1}H^n}, \]
and the equality holds if and only if the hypersurface is the cylinder. Therefore, \( a \) is a strictly-decreasing function in the family of unduloids with the cylinder as the initial surface.

Next we regard \( h_{\text{max}} \) as a function of \( a \) and differentiate the both sides of (86) with respect to \( a \) to get
\[ h'_{\text{max}}(a) = (a')^{-1} = \frac{1}{\{n + 1 \} H h_{\text{max}} + n} h_{\text{max}}^{n-1} > 0, \tag{90} \]
and \( h_{\text{max}} \) is a strictly-decreasing function in the family of unduloids with the cylinder as the initial surface. Hence,
\[ h_{\text{max}} < h_{\text{max}}(\text{cylinder}) = \frac{-n}{(n + 1)H}. \tag{91} \]
However, if \( h_{zz}(0, s) = 0 \) holds, using \( h_z(0, s) = 0 \), from (4), we have
\[ h_{\text{max}} = h(0, s) = \frac{-n}{(n + 1)H}, \tag{92} \]
which contradicts (91). Hence, \( h_{zz}(0, s) \neq 0 \) must hold. \( \square \)

B Computation of geometric quantities

B.1 Integral representations of geometric quantities of unduloids

The equation for \( h(z) \) that the mean curvature of hypersurface is constant can be obtained as the Euler-Lagrange equation
\[ \frac{d}{dz} \left( \frac{\partial J}{\partial h_z} \right) - \frac{\partial J}{\partial h} = 0, \tag{93} \]
with the following Lagrangian,
\[ J(z) = \sqrt{1 + h_z^2} h^n(z) + H h^{n+1}(z). \tag{94} \]
Here, $H$ is a constant representing the mean curvature of the hypersurface. Since Lagrangian (94) does not depend on $z$ explicitly, the following quantity is conserved,

$$J - \frac{\partial J}{\partial h} h =: C = \text{const.} \quad (95)$$

Substituting (94) into (95), we obtain a potential-form equation,

$$\left(\frac{dh}{dz}\right)^2 + 1 - \left(\frac{h}{C - H h^{n+1}}\right)^2 = 0. \quad (96)$$

Introducing a new variable $w$ by

$$w := -Hh, \quad (97)$$

we have

$$\left(\frac{dw}{dz}\right)^2 + (-H)^2 U(w) = 0, \quad (98)$$

$$U(w) := 1 - \left(\frac{w^n}{K + w^{n+1}}\right)^2, \quad K := (-H)^n C. \quad (99)$$

Denote the zeros of $U(w)$ by $w_\pm$ ($0 < w_- < w_+$). Then, it is easy to see that

$$\rho = \frac{w_-}{w_+}, \quad (100)$$

where $\rho = 1 - s$ is given by Eqs. (26) and (44).

Using $U(w_\pm) = 0$, one can express $w_\pm$ and $K$ as functions of $\rho$,

$$w_+ = \frac{1 - \rho^n}{1 - \rho^{n+1}} = \frac{\sum_{m=0}^{n-1} \rho^m}{\sum_{m=0}^{n} \rho^m}, \quad (101)$$

$$w_- = \frac{\rho(1 - \rho^n)}{1 - \rho^{n+1}} = \frac{\sum_{m=0}^{n-1} \rho^{m+1}}{\sum_{m=0}^{n} \rho^m}, \quad (102)$$

$$K = \frac{(1 - \rho)\rho^n(1 - \rho^n)^n}{(1 - \rho^{n+1})^{n+1}} = \frac{(\sum_{m=0}^{n-1} \rho^{m+1})^n}{(\sum_{m=0}^{n} \rho^m)^{n+1}}. \quad (103)$$

Here, the last expressions in Eqs. (101)–(103) are convenient to avoid the round-off errors in the numerical estimation for $0 < \rho \ll 1$ and large $n$.

From Eq. (98) with the assumption that $\frac{dw}{dz} \geq 0$, we obtain

$$dz = \frac{dw}{(-H) \sqrt{-U(w)}}. \quad (104)$$

Integrating the left-hand (resp. right-hand) side this with respect to $z$ (resp. $w$) from $z_1$ to $z_2$ (resp. from $w_-$ to $w_+$), we obtain

$$H = -\frac{1}{L} \int_{w_-}^{w_+} \frac{1}{\sqrt{-U(w)}} dw, \quad (105)$$

31
where $L := z_+ - z_-$ is the half period of the unduloid. This is an integral representation of the mean curvature of unduloid, which are functions of $\rho$ (or equivalently $s$) and $L$. Then, using Eqs. (1), (2), (97), and (104), the integral representations of the area and volume of half period of unduloid are obtained as

$$V = \frac{v_{n+1}}{(-H)^{n+2}} \int_{w_-}^{w_+} \frac{w^{n+1}}{\sqrt{-U(w)}} dw,$$

$$A = \frac{a_n}{(-H)^{n+1}} \int_{w_-}^{w_+} \frac{w^n \sqrt{1 - U(w)}}{\sqrt{-U(w)}} dw,$$

which are also functions of $\rho$ and $L$ again.

Without loss of generality, we can fix the interval $L$ ($L = 1$ for example) throughout the stability analysis. Thus, we have expressed the mean curvature, volume, and area of unduloid as integrals essentially depending only on the non-uniformness parameter $\rho$ (or $s$), Eqs. (105), (106), and (107). Therefore, as argued in Sec. 3.3, we do not have to solve $H_0(z) = \text{const}$ with boundary conditions $h_0(z_1) = h_0(z_2) = 0$, which needs iterative integration to satisfy the boundary conditions at the both boundaries.

### B.2 Manipulation for accurate numerical integration

What necessary to obtain $A(s), V(s),$ and $H(s),$ which play essential roles in the stability analysis, is to estimate the integrals numerically in Eqs. (105), (106), and (107) as accurately as possible. Since $U(w)$ vanishes at the both ends of integral range, the following manipulations help us to estimate the integral numerically \[.\] Those who are not interested in the numerics do not have to read the rest of this section.

Integrals (105), (106), and (107) can be rewritten as

$$Y = \int_{w_-}^{w_+} \frac{\psi_Y(w)}{\sqrt{-U(w)}} dw,$$

where

$$\psi_Y(w) := \begin{cases} 
\frac{1}{L} & (Y = H) \\
\frac{v_{n+1}w^{n+1}}{(-H)^{n+2}} & (Y = V) \\
\frac{a_nw^n \sqrt{1 - U(w)}}{(-H)^{n+1}} & (Y = A)
\end{cases}$$

In order to extract the poles of integrand, $w_{\pm}$, we rewrite the integral as

$$Y = \int_{w_-}^{w_+} \frac{(w^{n+1} + K)\psi_Y(w)}{\sqrt{(w^n + w^{n+1} + K)(w_+ - w)(w_+ - w_-)}} g(w) dw,$$

by defining

$$g(w) := \frac{w^n - w^{n+1} - K}{(w_+ - w)(w - w_-)} = \sum_{p=0}^{n-1} g_p w^p.$$
Here, the right-hand side defines the polynomial expression of \( g(w) \), which are regular at \( w = w_{\pm} \). The comparison of coefficients yields the following recursion relation and “boundary conditions” to be satisfied by \( g_p \) \((0 \leq p \leq n - 1)\),

\[
\begin{align*}
g_{n-1} &= 1, \quad (112) \\
(w_+ + w_-)g_{n-1} - g_{n-2} &= 1, \quad (113) \\
w_+ w_- g_{p+2} - (w_+ + w_-)g_{p+1} + g_p &= 0, \quad (0 \leq p \leq n - 3), \quad (114) \\
w_+ w_- g_1 - (w_+ + w_-)g_0 &= 0, \quad (115) \\
w_+ w_- g_0 &= K. \quad (116)
\end{align*}
\]

These can be easily solved to give the following expression of general term,

\[
g_p = (1 - \rho^{p+1})(1 - \rho^n)^{n-2-p} \left(\frac{\rho}{1 - \rho^{n+1}}\right)^{n-1-p} \quad (117)
\]

\[
= \frac{(\sum_{m=0}^{p} \rho^{m+1}) (\sum_{\ell=0}^{n-1} \rho^{\ell+1})^{n-2-p}}{(\sum_{k=0}^{n} \rho^{k})^{n-1-p}}, \quad (0 \leq p \leq n - 1). \quad (118)
\]

Again, the final expression is for the avoidance of round-off error.

Finally, we fix the integration range as

\[
Y = \int_{-1}^{1} \frac{(w^{n+1} + K)\psi_Y(w)}{\sqrt{(w^n + w^{n+1} + K)(1 - \zeta^2)g(w)}} d\zeta, \quad (119)
\]

by changing variable from \( w \) to \( \zeta \),

\[
w = \frac{w_+ + w_-}{2} + \frac{w_+ - w_-}{2} \zeta. \quad (120)
\]

One can accurately estimate \( H, V, \) and \( A \) numerically for given \( s = 1 - \rho \in (0, 1) \) (after fixing \( L, L = 1 \) for example) using Eq. (119) with Eqs. (101)–(103), (109), (111), (118), and (120).

### B.3 Area-volume diagrams

We describe here how to draw the area-volume diagrams in Fig. 3.

First, let us normalize volume \( V \) by the volume of the largest hemisphere, of which radius is identical to interval \( L := z_2 - z_1 \), and normalize surface area \( A \) by the surface area of the hemisphere whose radius is \( R \in (0, L) \),

\[
\hat{V} := \frac{V}{2 v_{n+2} L^{n+2}}, \quad (121)
\]

\[
\hat{A} := \frac{A}{2 a_{n+1} R^{n+1}}. \quad (122)
\]
Here, $V$ and $A$ are the volume and surface area, respectively, of a hemisphere, cylinder, or half-period of unduloid.

For the hemisphere with radius $R \in (0, L]$, the normalized volume and area are

\[
\hat{V}_{\text{hem}} = \frac{1}{2} v_{n+2} R^{n+2} L^{n+2} = \left( \frac{R}{L} \right)^{n+2}, \quad (0 \leq R \leq L),
\]

\[
\hat{A}_{\text{hem}} = 1,
\]

respectively. These give a parametric representation of the area-volume curve of hemisphere in Fig. 3 with $R/L \in (0, 1]$ being the parameter.

For the cylinder with radius $r \in (0, +\infty)$, the normalized volume and area are given by

\[
\hat{V}_{\text{cyl}} = \frac{v_{n+1} r^{n+1} L}{2 v_{n+2} L^{n+2}} = \frac{2 v_{n+1}}{v_{n+2}} \left( \frac{r}{L} \right)^{n+1}, \quad (0 \leq r < +\infty),
\]

\[
\hat{A}_{\text{cyl}} = \frac{a_n r^n L}{2 a_{n+1} R^{n+1}} = \left( \frac{a_n}{a_{n+1}} \right)^{\frac{1}{n+1}} \left( \frac{r}{L} \right)^n \left( \frac{L}{R} \right)^{n+1},
\]

respectively. Solving $\hat{V}_{\text{hem}} = \hat{V}_{\text{und}}$ for $R$ to obtain

\[
R = L \left( \hat{V}_{\text{und}} \right)^{\frac{1}{n+2}},
\]

and substituting this into the right-hand side of Eq. (129), one obtains

\[
\hat{A}_{\text{cyl}} = \left( \frac{2 a_n}{a_{n+1}} \right)^{\frac{1}{n+1}} \left( \frac{n + 1}{n + 2} \right)^{\frac{n+1}{n+2}} \left( \frac{L}{r} \right)^{\frac{1}{n+2}}.
\]

Equations (125) and (127) give a parametric representation of the area-volume curve of cylinder in Fig. 3 with $r/L \in (0, +\infty)$ being the parameter.

Denoting the volume and area of a half period of unduloid in the form of Eq. (119) by $V(s)$ and $A(s)$, the normalized volume and area of unduloid are given by

\[
\hat{V}_{\text{und}} = \frac{V(s)}{2 v_{n+2} L^{n+2}},
\]

\[
\hat{A}_{\text{und}} = \frac{A(s)}{2 a_{n+1} R^{n+1}}.
\]

Solving $\hat{V}_{\text{hem}} = \hat{V}_{\text{und}}$ for $R$ to obtain

\[
R = L \left( \hat{V}_{\text{und}} \right)^{\frac{1}{n+2}},
\]

and substituting this into the right-hand side of Eq. (129), one obtains

\[
\hat{A}_{\text{und}} = \left( \frac{2 a_n}{a_{n+1}} \right)^{\frac{1}{n+1}} \left( \frac{n + 1}{n + 2} \right)^{\frac{n+1}{n+2}} \left( \frac{L}{R} \right)^{\frac{1}{n+2}}.
\]

Equations (128) and (130) give a parametric representation of the area-volume curve of unduloid in Fig. 3 with $s \in (0, 1)$ being the parameter.
