**Abstract**  Cucumber (*Cucumis sativus* L.) and *Cucurbita* species (squashes, pumpkins, and gourds), belonging to the Cucurbitaceae family, are among the major vegetable crops in the world. Transgenic approaches could contribute to the accumulation of new knowledge of these species and to the development of elite cultivars. Despite this, research reports using transformants of these species are very limited so far. One of the reasons for this may be that although there are effective transformation methods, these methods are not well known among researchers. In the present review, we describe efficient protocols for the transformation of cucumber and squash plants and mention possible pitfalls in and advice for following these protocols. In addition, we discuss the current progress of genetic transformation research using cucumbers and squash, including genome editing.

**Key words:** *Cucumis sativus*, *Cucurbita* species, genome editing, regeneration, transformation.

**Introduction**

The cucumber (*Cucumis sativus* L.), belonging to the Cucurbitaceae family, is commonly consumed as a vegetable in daily life. In 2017, the global production of cucumbers was 83.8 million tons (FAOSTAT, http://www.fao.org/faostat/en/#home), of which China accounted for 77.4%. In Japan, cucumbers are also popular, with 0.56 million tons produced in 2017, making Japan the 10th largest producer of cucumbers in the world. Cucumber plants suffer from several diseases, such as downy mildew, powdery mildew, anthracnose, and cucumber mosaic virus, which limit crop production. Developing resistance to these diseases is a major subject of cucumber plant breeding (King et al. 2012). However, it is difficult to improve the tolerance of cucumbers to pathogen attack by conventional breeding due to the plant's narrow genetic base, with a genetic variability of only 3–8% (Plader et al. 2007). Squash (also pumpkin and gourd; *Cucurbita pepo*, *C. maxima*, and *C. moschata*) is another important vegetable in the Cucurbitaceae family. The global production of *Cucurbita* species reached 27.4 million tons in 2017 (FAOSTAT), primarily in China and India, which produced 29.1% and 18.7%, respectively, of all squash worldwide. The vegetables are used for food, animal feed, and ornamental purposes. Also, they are used as rootstocks for other cultivated cucurbits, including watermelon, cucumber, and melon, to strengthen tolerance to low temperatures and soilborne diseases (Davis et al. 2008). In addition, they have a unique ability to take up more organic xenobiotics and persistent organic pollutants from soil than the other plant families (Otani et al. 2007).

Next-generation sequencing (NSG) data have been acquired for cucumber and *Cucurbita* species (Huang et al. 2009; Montero-Pau et al. 2018; Sun et al. 2017). The analysis of this data allows for the discovery of new genes and regulatory sequences and confirmation of their positions, and makes available large collections of molecular markers. Genome-wide expression studies provide breeders with an understanding of the molecular basis of complex traits, such as the ripening process, phloem transport, disease resistance, cold tolerance, and fruit quality. Transformation approaches for cucumber and *Cucurbita* species would contribute to both basic science and molecular breeding.
The successful transformation of cucumber plants with *Agrobacterium rhizogenes* was first reported in 1986 (Trulson et al. 1986). A particle bombardment method of transformation was also reported in 1992 (Chee and Slightom 1992). In recent years, *Agrobacterium tumefaciens*-mediated transformation has been primarily used for cucumbers. Transgenic cucumber lines have been produced for the analysis of genes involved in pathogen resistance, stress tolerance, and sex determination (Narusaka et al. 2013; Wang et al. 2014; Zhang et al. 2014). Despite this, to our knowledge, there are few reports on stable transformation of squash to date. Tricoli et al. (1995) first reported the development of transgenic yellow crookneck squash lines (*C. pepo*) that exhibit multiple virus resistance, but the detail of their method remains enigmatic. The second article about the transformation of *C. pepo* was published in 2008 and reported a transformation efficiency of 0.7%. The successful transformation of *C. moschata* was achieved in 2011 (Nanasato et al. 2011), with a transformation efficiency of 2.7%. The transformation efficiency could be increased to 9.2% by applying vacuum infiltration to wounded explants to enhance *Agrobacterium* access to the cells in deeper layers (Nanasato et al. 2013b). We successfully transformed *C. pepo* and *C. maxima* using the same method.

Here, we present some information for researchers who are interested in tissue culture and transformation of cucumber and/or squash but have never worked with such approaches. The information given is based on our protocols for the transformation of cucumber and squash (Nanasato et al. 2011, 2013a, b; Nanasato and Tabei 2012, 2015; Tabei and Nanasato 2012) (Figure 1, Table 1). Even if specific procedures are followed, tissue culture and

**Figure 1.** Steps for the transformation of cucumber (cv. Shinhokusei No.1) and squash (cv. Heiankogiku) plants via direct-shoot organogenesis from cotyledonary explants. The compositions of shoot induction (SI) medium, inoculation (IN) medium, selection (SE) medium, and elongation (EL) medium are shown in Table 1. The concentration of *Agrobacterium* (OD<sub>600</sub>) is adjusted to 0.5 in INc for cucumber and 0.1 in INs for squash.

**Table 1.** Composition of culture media used for transformation of cucumber and squash.

| Plant species | Designation | Purpose of use | Composition |
|---------------|-------------|----------------|-------------|
| Cucumber      | Slc         | Shoot induction| MS salts and vitamins + 2 mg l⁻¹ BA + 1 mg l⁻¹ ABA + 3% (w/v) sucrose + 0.8% (w/v) agar, pH 5.7–5.8 |
|               | INc         | Inoculation    | MS salts and vitamins + 2 mg l⁻¹ BA + 1 mg l⁻¹ ABA + 10 mM MES + 3% (w/v) sucrose + 200 µM acetosyringone<sup>1</sup>, pH 5.2 |
|               | SEc         | Selection      | Slc medium + 50 mg l⁻¹ kanamycin<sup>1</sup> + 10 mg l⁻¹ meropenem<sup>1</sup>, pH 5.7–5.8 |
| Squash        | SIs         | Shoot induction| MS salts and vitamins + 1 mg l⁻¹ BA + 3% (w/v) sucrose + 0.8% (w/v) agar, pH 5.7–5.8 |
|               | INs         | Inoculation    | MS salts and vitamins + 1 mg l⁻¹ BA + 10 mM MES + 3% (w/v) sucrose + 500 µM acetosyringone<sup>1</sup>, pH 5.2 |
|               | SEs         | Selection      | SIs medium + 50 mg l⁻¹ kanamycin<sup>1</sup> + 10 mg l⁻¹ meropenem<sup>1</sup>, pH 5.7–5.8 |
| Common in cucumber and squash | EL           | Shoot elongation| 1/2 MS salts and vitamins + 1 mg l⁻¹ GA<sub>3</sub> + 1.5% (w/v) sucrose + 50 mg l⁻¹ kanamycin<sup>5</sup> + 10 mg l⁻¹ meropenem<sup>5</sup> + 0.8% (w/v) agar, pH 5.7–5.8 |

<sup>1</sup>The pH of all media in Table 1 is adjusted with NaOH before addition of agar and autoclave. <sup>5</sup>Add aseptically to sterilized media that has been cooled to approximately 55°C. ABA, abscisic acid; BA, 6-benzyladenine; GA<sub>3</sub>, gibberellin A<sub>3</sub>; MES, 2-(N-morpholino)ethanesulfonic acid; MS, Murashige–Skoog
transformation often fail. We identify possible pitfalls in documented protocols and provide suggestions to avoid them. Finally, we discuss the current progress of genetic transformation research on cucumbers and squash, including genome editing.

Preparation of explants for efficient regeneration

Various tissues, such as true leaves, hypocotyl, stem nodes, and cotyledons, have been used as explants in the regeneration and transformation of cucumber plants (Nishibayashi et al. 1996; Miao et al. 2009; Trulson et al. 1986; Ziv and Gadasi 1986). In 1994, Colijn-Hootmans et al. reported efficient regeneration of cucumber plants using the proximal end of young seedlings (1 day of preculture) (Colijn-Hooymans et al. 1994). The use of the proximal region of cotyledons as explants is often seen in the literature (Figure 2A, B) (Hu et al. 2017; Selvaraj et al. 2006, 2010; Vengadesan et al. 2005). After 1 day of preculture, cotyledons are detached from seeds using forceps. The distal parts of cotyledon are removed because they have no regeneration ability. The preparation process for squash explants is similar to that for cucumbers: immature cotyledons are excised from 1-day-old seedlings. However, especially in the case of squashes, care should be taken not to remove the cotyledonary nodes around the shoot apex by breaking off the hypocotyl (Figure 2C), because only this part retains regeneration ability, as reported previously (Ananthakrishnan et al. 2003; Kathiravan et al. 2006; Lee et al. 2003; Zhang et al. 2008). For the purpose of generating more transgenic shoots, we use the proximal parts of cotyledons, cut longitudinally into two pieces, as explants (Figure 2B, D). However, some groups use the whole proximal parts of cotyledons as explants.

Plant hormones for regeneration

Although indirect organogenesis via somatic embryogenesis has been reported in cucumber plants (Burza et al. 2006; Chee 1990; Raharjo and Punja 1994), direct organogenesis has an advantage over indirect organogenesis in terms of time for regeneration. Murashige-Skoog (MS) medium (Murashige and Skoog 1962) with 1–2 mg l⁻¹ 6-benzyladenine (BA) and 0.5–1.0 mg l⁻¹ abscisic acid (ABA) has been shown to lead to efficient regeneration of cucumber plants (Tabei et al. 1998; Zhang et al. 2017), whereas in squash, the addition of ABA caused necrosis (Nanasato et al. 2011). For squash cultivars, MS medium with 1 mg l⁻¹ BA was used for regeneration (Kathiravan et al. 2006; Nanasato et al. 2013b; Zhang et al. 2008).

Strains of Agrobacterium tumefaciens

The use of particle bombardment for gene transfer was reported in cucumber plants (Kodama et al. 1993; Schulze et al. 1995). Currently, an Agrobacterium-mediated transformation method is more commonly used for gene transfer; strains EHA105 and LBA4404 can be used similarly in the transformation of cucumber and squash. In our case, EHA 105 harboring the pBI121-derived binary vector was cultured with Luria–Bertani (LB) medium containing 10 mM 2-(N-morpholino)ethanesulfonic acid (MES), 50 mg l⁻¹ kanamycin, 25 mg l⁻¹ chloramphenicol, 25 mg l⁻¹ rifampicin and 20 µM acetosyringone, pH 5.2 at 28°C until the optical density at 600 nm (OD₆₀₀) reached 0.4–0.8. The bacterial cells were pelleted and resuspended in inoculation medium (IN), and the concentration of Agrobacterium (OD₆₀₀) was adjusted to 0.5 in INc for cucumber and 0.1 in INs for squash (Table 1).

Physical treatments performed during Agrobacterium infection

Physical treatments, such as vacuum infiltration and wounding, during Agrobacterium infection are the most important factors in the successful transformation of cucumber and squash (Figure 3A–C). These treatments contribute to increased Agrobacterium inoculation
efficiency in deeper layer cells, which seem to have the potential of organogenesis (Nanasato et al. 2013b). The effectiveness of vacuum infiltration has been confirmed in reports from other research groups (Hu et al. 2017; Zhang et al. 2017). Whiskers, which are white needle-like crystals with very high tensile strength, can be used to wound squash explants (Figure 3D, E) (Nanasato et al. 2011, 2013b). In addition, the cocultivation of explants on filter paper moistened with coculture medium can significantly contribute to improved transformation efficiency (Figure 3F).

Selection and rooting of nonchimeric transgenic lines
A combination of the neomycin phosphotransferase II (NPTII) gene and kanamycin has been frequently used for the selection of transformants. The regeneration of escape shoots is almost unavoidable, even under stringent selection conditions (Figure 4A, D). Therefore, the use of visual markers, such as green fluorescent protein (GFP), is the key for obtaining cucumber and squash transformants. Furthermore, transgenic shoots developed via direct organogenesis are often chimeric. Chimeric individuals are composed of a mixture of transformed and nontransformed cells. The use of visual markers is effective for the discrimination of
sectorial chimeras (Figure 4B, C, E, F). Root elongation in chimeric individuals is frequently inhibited in media containing antibiotics. Multiple rounds of axillary bud induction in the selection medium are a powerful way to generate solid transformants from chimeric individuals. Supplementation of the growth media with low concentrations of auxins, such as indole-3-butryic acid (IBA) and 1-naphthaleneacetic acid (NAA), to promote rooting is recorded in some research papers (Sarmiento et al. 1992; Vasudevan et al. 2007; Zhang et al. 2008). However, auxin-induced chlorosis of the regenerated leaves was also reported (Hu et al. 2017). In many cases, it seems unnecessary to add auxin to promote rooting. After shoots with vigorous roots grow four to five nodes (about 10 cm in height), the shoots should be transplanted to soil as described previously (Nanatsato and Tabei 2012, 2015; Tabei and Nanatsato 2012).

Application of genome editing technology in cucumber and squash

Since the announcement of CRISPR/Cas9 technology in 2012 (Jinek et al. 2012), genome editing technology has been spreading rapidly in plant functional genomics research and crop improvement. To date, two research groups have reported successful genome editing in cucumber plants using the CRISPR/Cas9 system (Hu et al. 2017; Sherman et al. 2016). Both groups succeeded in producing transgene-free null segregant lines via crossing. The CRISPR/Cas9 system was also used for functional analysis of a gene encoding NADPH oxidase in C. moschata (Huang et al. 2019).

Conclusion

Research on cucumber and squash has been improved due to the development of genome information. Cucumber is one of the potential candidates for a model plant of the Cucurbitaceae family and would provide new scientific knowledge through molecular analysis. In addition, genome editing technology could contribute to the rapid breeding of cucumber and squash. Transformation techniques will play an increasingly important role in the progress of basic science and molecular breeding. In this review, we describe methods of transformation of cucumber and squash plants based on reports we published previously. We emphasize that the concentration of plant hormones for regeneration and conditions for Agrobacterium infection should be adjusted according to the plant cultivar treated. We hope that this review will contribute to the development of Cucurbitaceae plant research and molecular breeding.
