Abstract. Today, the use of smart transportation systems has become widespread due to the change in the structure of cities, technological developments, and the increase in the number of vehicles. It aims at targets such as reducing the damage to people and the environment by increasing traffic safety with smart transportation systems. In addition, one of the big problems of long-distance drivers is falling asleep while driving. This is an event that puts both the driver’s life, the passengers in the vehicle, and the vehicles on the road in danger, and puts the company in a difficult situation if it works for a company. In this direction, the driver sleep alarm project has been developed. This project is a control system based on monitoring the user, measuring, and analyzing their movements. Literature research, which is the first stage of the project, was conducted and research continued throughout the project process. Within the scope of this project, a headset was designed for the driver’s sleep alarm and a mobile application was created. The first prototype of the project was built. First, in the project, the angle values made by the driver’s head were produced with the IMU connected to the microcontroller. 10° to 20° margins identified as sleeping state for roll, pitch, and yaw angles. Later, a wearable headset was designed for the driver. Based on these angles produced in the microcontroller, an algorithm has been created that detects whether the driver is asleep. These generated angle values and status information were transferred from the headset to the mobile application via Bluetooth. This data transferred in the mobile application is reflected on the screen. In addition, an algorithm has been created in the mobile application, which sends a notification to the driver when sleep status is detected and sends an informative SMS to the headquarters if the driver is unresponsive to this notification. For the second prototype, it was aimed to produce a PCB for the headset and thus make a new mechanical design. Data mining applications are planned with the collected data from drivers for future works.

Keywords: driver drowsiness detection, transportation safety, smart transportation.

1. Introduction

Many deaths occur today due to drowsiness, fatigue, and drowsiness of the driver. This is an event that endangers the life of the driver, the passengers in the vehicle, the vehicles, and pedestrians on the road, and puts the company in a difficult situation if it works for a company. With the development of technology, different methods have been developed to detect driver fatigue in advance and to prevent this situation. They can basically be divided into 4 categories: bio-based detection, physical-based detection, vehicle-based detection, and hybrid-based detection.

Biological signals can be used to detect fatigue and sleep status. It can be classified as heart, brain, eye, and skin-based signals. Signals such as electroencephalography (EEG), electrocardiogram (EKG), electro-oculography (EOG), and surface electromyogram (EMG) are used to detect this condition. As a result of the research, the accuracy rates of these methods are
satisfactory [1].

On the detection of drowsiness, there are successful projects such as a probability model and a smart watch-based wearable EEG device, a detection system using wireless wearable sensors [2], using a Support Vector Machine (SVM) [3], and the development of six classifiers based on the sEMG feature. There are also projects in which head movements and facial expressions are used [4-7]. It is seen that these system designs are not sufficient on their own and the systems require a high level of optimization. It is recommended to use methods such as deep neural network model embedded system [8], vehicle-based detection or an online fatigue detection method based on steering angle data [9], and Hybrid Feature Based Detection for modeling systems. In this article, the detection method based on the physically based head position situation is used. While the most important factor in the selection of this method includes the methods that mostly require a camera and affect the driving performance of the driver, the detection method based on the physical-based head position has been adopted here.

In this study, a headset to hang on the ear of the vehicle driver is designed. The designed headset measures the driver's head angle and decides the sleep state by using the vehicle's navigation system. If there is a possibility that the driver may have fallen asleep or had an accident, the application running on the navigation system sends an SMS message to the monitoring center with the status and vehicle coordinates.

2. Materials and methods

The system consists of an ABS-based structure produced with a 3D printer and IMU (Inertial Measurement Units), Bluetooth Module, Microcontroller (MCU), and Battery placed on this structure. The system uses the possible movement planes of the press. In this study, DMP Data Fusion was used to measure roll, pitch, and yaw angles.

The product designed on Fusion 360 was printed with a 3D printer as shown in Fig. 1. The design, which was first made in Fusion 360, was transferred to Ultimaker Cura to print the product from the 3D printer. Ultimaker Cura is slicing software for 3D printers. It translates the 3D model into G codes that the 3D printer can understand. Necessary settings for printing were made on Ultimaker Cura. These settings are the shape and size of the design, the temperature of the printed material, the adjustment of the places where support is needed, etc. while printing. are settings. The file with the generated G codes was uploaded to the 3D printer and 3D printed. Ultimaker 2+ was used for the 3D production of the headset. Table of production parameters are also given in Table 1.

| Used material | PLA ø1.75 mm | Layer height | 0.2 mm |
|---------------|--------------|--------------|--------|
| Infill density| 100 %        | Line width   | 0.38 mm|
| Infill pattern| Cubic        | Printing temperature | 210 °C |
| Top/bottom thickness | 0.8 mm | Printing temperature of initial layer | 230 °C |
| Top/bottom layer count | 4 | Build plate temperature | 75 °C |
| Wall thickness | 0.76 mm | Build plate temperature of initial layer | 75 °C |
| Line count    | 2           | Print speed  | 50 mm/s|

After the mechanical design is drawn and produced from a 3D printer, the components that were soldered before are placed inside the headset.

A comparison the product with other similar products is given in Table 2.

3. Results

In this study, the driver's sleep state was estimated by calculating the angle of the driver's head according to the head position. The design realized with Arduino pro micro, GY87 IMU and HC05 Bluetooth and the goal has been achieved with the angle values given in Table 3.

a) Printing of the headset case
b) Usage of the headset

Fig. 1. 3D printing of the headset case

Table 2. Comparison of similar products

| LGI driver fatigue alarm | Cure sleepiness right away | Car driver sleepy reminders | Developed remote driver sleep monitor |
|-------------------------|---------------------------|-----------------------------|--------------------------------------|
| Only works within 15°-20° angle values | Only works when the head falls forward | Only works when the head falls forward | Works in situations where the head falls to the right, left, front and back |
| Soft but heavy | Relatively hard but very lightweight | Soft and lightweight | Relatively hard and lightweight |
| Rechargeable | Non-rechargeable | Non-rechargeable | Rechargeable |
| Warns the driver with sound and vibration | Warns the driver with sound and vibration | Warns the driver with sound and vibration | Warns the driver via the mobile application and waits an action from the driver. If driver won’t reply, it sends the coordinates of the driver to the observer |

Table 3. Headset sleep detection angles

| Head position | Yaw | Pitch | Roll |
|---------------|-----|------|------|
| Tilted left   | 315° < \( \theta_{yaw} \) < 330° | 135° < \( \theta_{pitch} \) < 145° | 85° < \( \theta_{roll} \) < 100° |
| Tilted right  | 295° < \( \theta_{yaw} \) < 310° | 140° < \( \theta_{pitch} \) < 150° | 135° < \( \theta_{roll} \) < 145° |
| Tilted down   | 330° < \( \theta_{yaw} \) < 355° | 0° < \( \theta_{pitch} \) < 20° | 80° < \( \theta_{roll} \) < 90° |
| Tilted up     | 280° < \( \theta_{yaw} \) < 290° | 100° < \( \theta_{pitch} \) < 120° | 100° < \( \theta_{roll} \) < 120° |

A headset has been designed to keep these modules that detect the head position and to be worn by the driver. According to the results, it was thought that this design could be reduced. Then, an interactive mobile application was designed to follow the driver. Thanks to this application, when the driver is predicted to be asleep, an alarm is sent to the driver. Despite this estimation being wrong, the driver was given 5 seconds to stop the alarm. For the alarm that is not stopped within 5 seconds, an SMS was sent to the headquarters of the driver.

4. Conclusions

In this project, it is aimed to make a product that works in accordance with its purpose. As a result of the project, the product targeted criteria were realized.

This design can be used for monitoring fleet drivers. A project can be developed to determine sleep tendencies and factors that cause sleep.

For now, from 10° to 20° limit angles are identified of sleeping state for roll, pitch, and yaw for the headset, but a self-calibrating system is planned for future studies.
Artificial intelligence and machine learning methods will be used with the collected data from drivers to learn where and in what conditions drivers sleep or accidents happen [10, 11].

In the planned studies, it is envisaged to use system identification methods like airplane calibration systems, so that the headset can self-calibrate [12]. Also, this product will be produced with plastic injection method instead of 3-D printing, using lean production techniques and innovative design techniques, with less cost and less errors [13, 14].

Acknowledgements

This project was supported by Alışan International Transports Company.
The project team received an incentive award with the success of 2242 University Students Research Projects Competitions held under TEKNOFEST Aviation, Space and Technology Festival organized by The Scientific and Technological Research Council of Turkey (TÜBİTAK).

Data availability

The datasets generated during and/or analyzed during the current study are available from the corresponding author on reasonable request.

Zeynep Ekşi is currently an undergraduate student in Marmara University, Mechatronics Engineering Department with Electrical and Electronics Engineering minor. Her current research interests include electronic circuit analysis and design, embedded systems, and robotics.

Ayşe Nur Cengöz received her B.Sc. from Marmara University, Mechatronics Engineering Department and is currently an undergraduate minor student of Electrical and Electronics Engineering Department. Her current research interests include electronic circuit analysis and design, embedded systems, control systems, and soft robotics.

Melike Özarslan received her B.Sc. from Marmara University, Mechatronics Engineering Department. Her current research interests include web and mobile applications design, chemical process design, and supply chain management.

Emre Sözer was graduated from Istanbul University as Environmental Engineer. He also has a master’s degree about Occupational Health and Safety. He has been working as HSE (Health, Safety and Environment) and Dangerous Goods Logistic Operations professional with 10 years of experience in logistics, warehouse, transportation, manufacturing, and waste management sectors. His aim is to contribute for improving logistics sector's safety processes.
Mehmet Fatih Çelebi received his B.Sc. and M.Sc. degrees in electrical and electronics engineering from Çukurova and Marmara Universities, in 2013 and 2017. Now he is a Ph.D. candidate and works as research assistant in Marmara University, Istanbul. His current research interests include electronic circuit analysis and design, embedded systems, control systems, and soft robotics.

Ahmet Feyzioglu received his B.Sc., M.Sc., and Ph.D. degrees in mechanical engineering from Marmara University. He also has a M.Sc. degree in Industrial Engineering from Middle East Technical University. His current research interests include mechanical design and production, system identification and control, and sustainability.
