Abstract
The three species of Nerthra Say, 1832 (Hemiptera: Heteroptera: Gelastocoridae) occurring in China are reviewed. Dorsal habitus photographs of the two species, Nerthra asiatica (Horváth, 1892) and Nerthra indicia (Atkinson, 1889), are provided, accompanied by illustrations of male genitalic structures and female ventral aspect of posterior abdominal segments. The male of Nerthra asiatica is recorded and reviewed for the first time.

Keywords
Hemiptera, Gelastocoridae, Nerthra, China

Introduction
Toad bugs (Gelastocoridae) are a remarkable group of aquatic bugs (Nepomorpha) which are derived from aquatic ancestors and have become secondarily terrestrial (Hegsgaard et al. 2004). Gelastocoridae contains three recent genera and approximately 103 species distributed worldwide, but much more prevalent in the tropics (Polhemus 1995). It is divided into two subfamilies, Gelastocorinae and Nerthrinae. Recent Gelastocorinae (two genera) are reported in only in America, from southern Canada.
to north Argentina (Štys and Jansson 1988; Chen et al. 2005), but there is one fossil species, *Gelastocoris curious* Poinar & Brown, 2016 described from Burmese amber (Poinar and Brown 2016). The Nerthrinae includes one fossil genus, *Cratonerthra* Martins-Neto, 2005 with two species (Ruf et al. 2005), and one recent genus, *Nerthra* Say, 1832, currently including 92 valid recent species, of which nine species occur in south-eastern Asia west of Wallace line, and three species present in China (Kment and Jindra 2008, Xie and Liu 2013, Faúndez and Ashworth 2015).

**Material and methods**

The male genitalia were examined in glycerol and illustrated using a Zeiss Discovery V8 microscope. All measurements are given in millimetres (see Table 1). The digital photographs of specimens (Fig. 1A–D) were taken with a Zeiss Discovery V20 camera. All the studied specimens are deposited in the Institute of Entomology, Nankai University (NKUM), Tianjin, China.

**Systematics**

*Nerthra asiatica* (Horváth, 1892)

* these measurements are from Polhemus and Polhemus 2012 and Todd 1955.

margin nearly straight, not expanded laterally at middle. Connexivum greatly expanded laterally in females. Bristles short or moderately long, clavate, slightly curved, bristles in rows and clumps on hemelytra and in clumps on scutellum and pronotum.

**Abdomen.** Abdominal V-IV sternites of male mostly asymmetrical, ninth sternite rather oval, wider than long, not as long as eighth sternite; seventh sternite sternite about half as long as eighth sternite; fifth sternite very short medially (Fig. 2E). In female, abdomen nearly symmetrical. Lobes of ovipositor slightly projecting posteriorly; posterior margin of last visible abdominal sternite triangularly emarginate (Fig. 2F).

**Distribution.** China (Sichuan Province, Hubei Province, Xizang (Tibet) Autonomous Region), India (Todd 1955, Kment and Jindra 2008).

**Remarks.** This is the first time the male has been described. In the shape of the pronotum it would seem to be closely related to *N. spissa* (Distant, 1911), but the right paramere (Fig. 2C–D) of these two species is different. *Nerthra spissa* has a rather large male clasper for the size of the insect, nearly straight, cylindrical, abruptly narrowed to point at apex, twisted, and the aedeagal furrow obliquely crossing the basal half of clasper. This species differs from *N. indica* (Atkinson, 1889) by the its larger body size and the shapes of the tubercles of the head, the lateral margin of the pronotum, the hind wing (Fig. 2G), and the structures of male and female genitalia.

Figure 2. Nerthra asiatica (Horváth). A–B Genital capsule in different views C–D Right paramere in different views E Ventral view of posterior abdominal segments of male F Female subgenital plate G hind wing.

The holotype is a female from China: Flumen Poi-ho (G. N. Potanin) [= Sichuan, Gar Qu (= Pai Ho River)] (Kiritshenko 1926; Todd 1955; Polhemus 1995). The para-type of Mononyx grossus Montandon in the Francis Huntington Snow Entomological Collection at the University of Kansas was labelled ‘Thibet (Mou-Pin)’ [= Sichuan, Ya’an (= Mou-ping country)] (Todd 1955). This species found in Mêdog county is reported from Xizang (Tibet) Autonomous Region for the first time.

Figure 3. *Nerthra indica* (Atkinson). A–B Genital capsule in different views C–D Right paramere in different views E Ventral view of posterior abdominal segments of male F Female subgenital plate G hind wing.

Body shape most closely related to *N. lobata* (Montandon, 1899) from which it may be separated by the male genitalia shape (Fig. 3A–D), the smaller ovipositor lobes which are less projecting, and the lack of lateral submarginal tumescences of the last visible abdominal sternite in the females.

**Abdomen.** Abdomen greatly expanded laterally in females. Bristles mostly short and clavate, groups of long black bristles on basal tumescences and median part of pronotum. Abdominal sternites of male mostly asymmetrical, but nearly symmetrical in female. Lobes of ovipositor asymmetrical slightly lobed and projecting posteriorly. Ninth sternite wider than long, not as long as eighth sternite; seventh sternite sternite about half as long as eighth sternite; fifth sternite very short medially. Right paramere swollen apically and stick out at middle.

**Remarks.** Body shape most closely related to *N. lobata* (Montandon, 1899) from which it may be separated by the male genitalia shape (Fig. 3A–D), the smaller ovipositor lobes which are less projecting, and the lack of lateral submarginal tumescences of the last visible abdominal sternite in the females.

**Distribution.** China (Jiangxi, Fujian, Guangxi Zhuang Autonomous Region, Sichuan, Guizhou, Yunnan, Xizang (Tibet) Autonomous Region), India, Nepal, Vietnam, Laos (Todd 1955; Kment and Jindra 2008).

Description (from Todd 1955). Body light brown, front of head provided with five large, rounded tubercles, four of which are flatted on top and densely covered with short clavate bristles; ocelli absent. Pronotum greatly expanded laterally; lateral margins converging anteriorly, subparallel for posterior half; posterior angle projecting obliquely posterolateral, rather pointed; posterior margin with five concavities. Scutellum rather small, apex narrowed, basal portion depressed, inclining to apex which is the most elevated part. Hemelytra entirely coriaceous, fused together, extending slightly beyond end of abdomen, large longitudinal carinae present; base of embolium greatly expanded laterally. Connexivum broadly expanded laterally in both sexes. Entire body covered with short, broadly clavate bristles, bristles pale and especially dense on pronotum and on the elevations of the head.

Abdominal sternites of female nearly symmetrical except for posterior margin of last sternite, which is slightly emarginated, but with apex slightly convex just below the lobes of the ovipositor, the latter somewhat rounded and the left one overlapping the right. Abdominal sternites of male rather small, last visible abdominal sternite wider than long, nearly twice as long as seventh sternite, which has the right side elongate, spatulate.

Clasper of male rather sickle-shaped, but nearly straight, very slightly enlarged at apex then tapering to a blunt point.

Notes. During the daytime this species hides in wet mud or sand, or under stones or plant debris (Chen et al. 2005). Nieser and Chen (2005) observed these toad bugs burrowing in the sand on a beach in the south of Taiwan. In view of its inability to fly, its wide distribution is attributed to dispersion by drift on plant debris (Todd 1960). The authors have not seen this species, and distribution data for this species was collected from the published literature.

Distribution. China (Taiwan), Japan, Philippines, Malaysia, Indonesia, Australia (Kment and Jindra 2008).
