Plants are sessile organisms that have evolved a complex immune system which helps them cope with pathogen attacks. However, the capacity of a plant to mobilize different defense responses is strongly affected by its physiological status. Nitrogen (N) is a major nutrient that can play an important role in plant immunity by increasing or decreasing plant resistance to pathogens. Although no general rule can be drawn about the effect of N availability and quality on the fate of plant/pathogen interactions, plants' capacity to acquire, assimilate, allocate N, and maintain amino acid homeostasis appears to partly mediate the effects of N on plant defense. Nitric oxide (NO), one of the products of N metabolism, plays an important role in plant immunity signaling. NO is generated in part through Nitrate Reductase (NR), a key enzyme involved in nitrate assimilation, and its production depends on levels of nitrate/nitrite, NR substrate/product, as well as on L-arginine and polyamine levels. Cross-regulation between NO signaling and N supply/metabolism has been evidenced. NO production can be affected by N supply, and conversely NO appears to regulate nitrate transport and assimilation. Based on this knowledge, we hypothesized that N availability partly controls plant resistance to pathogens by controlling NO homeostasis. Using the Medicago truncatula/Aphanomyces euteiches pathosystem, we showed that NO homeostasis is important for resistance to this oomycete and that N availability impacts NO homeostasis by affecting S-nitrosothiol (SNO) levels and S-nitrosoglutathione reductase activity in roots. These results could therefore explain the increased resistance we noted in N-deprived as compared to N-replete M. truncatula seedlings. They open onto new perspectives for the studies of N/plant defense interactions.

Keywords: nitrogen metabolism, plant immunity, Aphanomyces euteiches, Medicago truncatula, nitric oxide homeostasis

NITROGEN AND THE PLANT IMMUNE RESPONSE

Plants are under the constant threat of pathogen attacks that limit their survival and are major yield-limiting factors. In response to these attacks, plants activate multiple defense reactions both at the site of infection and systemically, which in many cases lead to resistance. These reactions include massive transcriptional reprogramming, cell wall reinforcement, synthesis of...
Pseudomonas syringae expression was evidenced upon infection by the bacterium in transporters to plant defense has recently been highlighted family (Krapp, 2015). The contribution of several of these NPF NRT2 driven by nitrate transporters from the multigenic assimilated reductase (NR) and nitrite reductase (NiR), respectively, is using plant mutants: et al., 2010). The role of specific transporters was demonstrated (deficient in the expression of the AMT1.1 and NPF family were recently proposed to play a role as amino acid sensors during plant defense, perhaps by sensing changes in extracellular amino acids caused by pathogen infection (Forde and Roberts, 2014). Crosstalk between N metabolism and phytohormones can also interfere with plant stress responses and could be considered as a mechanism involved in the partitioning of available resources between defense and growth. For instance, N limitation induced the accumulation of salicylic acid (SA) in A. thaliana leaves (Yaeno and Iba, 2008). Conversely, ethylene/jasmonic acid signaling coordinated the upregulation of the nitrate transporter NRT1.8 (AtNPF7.2) and the downregulation of NRT1.5 (AtNPF7.3) genes to tune NO$_3^-$ reallocation in plants from the shoot to the roots under stress conditions (Zhang et al., 2014). Finally, experiments on rice showed that N-induced susceptibility to Magnaporthe oryzae is genotype-dependent, and may be linked to N use efficiency (Ballini et al., 2013). These interesting data raise the question of the genetic control of N effects on plant immunity. The identification of the corresponding QTLs will permit to uncover new molecular actors of N-controlled resistance to pathogens.

NITRIC OXIDE AND N METABOLISM

The role of NO in plant defense is widely accepted. NO is involved in transcriptional regulation of defense genes encoding PR proteins or proteins involved in phytoalexin synthesis, SA accumulation, and post-translational protein modifications (Wendehenne et al., 2014). NO is a nitrogen species produced via a variety of pathways in plants (reviewed by Gupta et al., 2011c). Briefly, these pathways can be classified into two groups according to nitrogen-containing precursors: the l-arginine-dependent pathway (oxidative pathway), and the NO$_2^-$ dependent pathway (reductive pathway). NO$_2^-$-dependent NO synthesis involves NR which reduces NO$_2^-$ to NO both in vitro and in vivo in specific physiological contexts (Yamasaki and Sakihama, 2000); alternatively, formation of NO through the reduction of NO$_2^-$ by the mitochondrial respiratory chain can also be observed, particularly in roots (Gupta et al., 2011a; Horchani et al., 2011). Finally, NO can be produced by an apoplastic non-enzymatic conversion of NO$_3^-$ to NO at acidic pH, in the presence of reductants such as ascorbic acid (Bethke et al., 2004).

Several pathways involved in NO transformation and turnover and balancing the bioavailability of this molecule have been identified (Leitner et al., 2009). Firstly, NO can react with reduced glutathione to produce S-nitrosogluthathione (GSNO), a low-molecular-weight S-nitrosothiol (SNO) that is more stable than NO and considered to be a mobile reservoir of NO. The cellular level of GSNO is enzymatically regulated primarily by GSNO reductase (GSNOR), which catalyzes the reduction of GSNO to oxidized glutathione and ammonium. Importantly, Yun et al. (2016) recently reported that NO and GSNO have additive functions in plant immunity but also in plant development. NO and GSNO might have distinct or overlapping molecular targets, thus allowing differential control of key cellular processes belonging to both defense and development. Secondly, besides their O$_2^-$ binding properties, hemoglobins (Hbs) can metabolize NO into NO$_3^-$ and therefore are also considered as NO and NO$_2^-$ concentration modulators (Gupta et al., 2011b). Finally, NO rapidly reacts with superoxide (O$_2^-$) to
form peroxynitrite (ONOO\(^-\)), an oxidizing and nitrating RNS produced for instance in plant cells during immune responses (Vandelle and Delledonne, 2011). These molecules associated with NO turnover also play a role in the plant immune response. For instance, GSNO plays a key role in mediating the structural and functional changes of NPR1, a key transcription coactivator of plant immunity (Tada et al., 2008).

Nitric oxide is partly produced through NR, dependent on its substrate/product NO\(_3^-\) / NO\(_2^-\) as well as on l-arginine and polyamines. As a result, cross-regulation between NO signaling and N supply/metabolism is expected. Several lines of evidence show that NO production is likely to be affected by N supply. In a physio-pathological context, plant NO production is dependent on the form of N supply, Besson-Bard et al. (2008) and Gupta et al. (2013) showed that tobacco cell suspensions or leaves from plants grown on ammonium instead of nitrate as an N source emitted less NO when elicited by cryptogein or P. syringae. Thus these data highlight the determining role of the N source on the rate of NO synthesis. Modifications of the intracellular concentration of diverse intermediates of N metabolism such as amino acids or polyamines also result in the modulation of NO production. For instance, exogenously added polyamines induced rapid NO biosynthesis in A. thaliana (Tun et al., 2006). In the same manner, overexpression of the Asparagine synthetase 1 gene significantly enhanced the NO burst (Hwang et al., 2011). Finally, N nutrition could also impact important redox molecules associated with NO homeostasis. Nitrate deprivation led to altered levels of ROSs in A. thaliana and tobacco (Schachtman and Shin, 2007; Besson-Bard et al., 2008). Pathogen-induced expression of the nitrate transporter NRT2.6 was also correlated with ROS accumulation (Dechorgnat et al., 2012). Concentrations of antioxidant molecules such as glutathione (GSH) were altered (decreased in shoots and increased in roots) in A. thaliana and barley plants exposed to N deficiency (Kandlbinder et al., 2004; Kovacik et al., 2014).

Reciprocally, NO and derived RNS could participate in the regulation of N metabolism. NO can control physiological processes by modifying gene transcription. By analyzing available literature and databases, we identified interesting candidates likely to contribute to the crosstalk between N metabolism and NO among the numerous NO-regulated genes. Transcriptomic studies highlighted the up- or down-regulation of transcripts encoding N transporters (Ahlfors et al., 2009; Corti Monzon et al., 2014; Trevisan et al., 2015) or N assimilation/remobilization genes (Ferrarini et al., 2008; Ahlfors et al., 2009; Xu et al., 2013; Begara-Morales et al., 2014; Corti Monzon et al., 2014; Zeng et al., 2014; Trevisan et al., 2015) and amino acid metabolism-related genes (Ferrarini et al., 2008; Xu et al., 2013) upon modulation of NO homeostasis by treatment with NO donors, NO scavengers, or using mutants affected in NO homeostasis. Physiological studies identified NO as a regulator of N uptake in Chlamydomonas reinhardtii, possibly through the control of the expression of the nitrate or ammonium (AMT1.1 and AMT2.2) transporters. In A. thaliana, the expression of the high affinity nitrate transporter NRT2.1 was down-regulated by NO donors and in a GSNO knock-out mutant, but the expression of the low-affinity nitrate transporter NRT1.1 remained unaltered (Frunzillo et al., 2014), suggesting a switch from high- to low-affinity nitrate transport. By contrast, the expression of NRT2.1 was up-regulated through an NO-dependent process in A. thaliana roots exposed to cadmium (Besson-Bard et al., 2009). In addition to NO-mediated transcriptional regulation, many of NO biological functions arise as a direct consequence of chemical reactions between proteins and NO/RNS. Metal-nitrosylation, S-nitrosylation, and tyrosine nitration are notably emerging as main NO-dependent post-translational protein modifications (Astier and Lindermayr, 2012). Among the soluble proteins identified as S-nitrosylated or Tyr-nitrated, possible candidates contributing to the NO/N metabolism interplay are mainly involved in both N assimilation/remobilization and amino acid metabolism (Table 1). Post-translational inhibition of high-affinity ammonium and high-affinity NO\(_3^-\) / NO\(_2^-\) transporters by NO was highlighted in C. reinhardtii (Sanz-Luque et al., 2013). However, whether the reversible effect of NO was linked to S-nitrosylation of the transporters or to an indirect effect of NO leading to other post-translational modifications of the transporters remains to be determined (Sanz-Luque et al., 2013). In that same study, NO also inhibited NR activity reversibly, but not NiR or GS activity. This post-translational effect of NO on N transporters and NR might mediate the fast inhibition of N uptake and assimilation by ammonium in C. reinhardtii. More recently, inhibition of NR activity by NO was proposed to be partly mediated by a truncated hemoglobin THB1 whose gene expression is highly induced by NO (Sanz-Luque et al., 2015).

In higher plants, NO produced by denitrification in the rhizosphere of forest soils impacts N uptake without affecting gene expression patterns of putative T transporters, suggesting post-translational modification of these transporters (Dong et al., 2015). NR is also highly regulated by complex transcriptional and post-translational mechanisms. Studies on different models using NO donors, NO synthase inhibitors, or the scavenger cPTIO indicate that NO modulates NR activity. Results are sometimes contradictory. NR activity in leaves was inhibited under high NO concentrations (Rosales et al., 2011, 2012; Frunzillo et al., 2014), but was enhanced in cabbage (Du et al., 2008). Moreover, the inhibition or activation of NR by NO in tomato roots could depend on the NO\(_3^-\) concentration (Jin et al., 2009). The mechanisms explaining these effects of NO on NR are poorly understood. Regulation of NR by NO could occur through transcriptional downregulation of the NR NIA genes in Chlamydomonas and A. thaliana (de Montaigu et al., 2010). A direct interaction of NO with NR is possible, as S-nitrosylation of NR was evidenced in poplar exposed to cold stress (Cheng et al., 2015). Glutamine synthetase 2 is a second key enzyme of plant N metabolism involved in the synthesis of essentially nitrogenous compounds via Gln production. Interestingly, GS1 and GS2 were identified as molecular targets of NO (Table 1). GS activity was inhibited by Tyr nitration in root nodules of Medicago truncatula. This post-translational modification may mediate channeling of glutamate to boost plant antioxidant defenses (Melo et al., 2011) in response to NO. This interesting feature does not seem to be shared across the plant kingdom.
therefore first assessed whether changes in NO homeostasis could
indeed affect *M. truncatula* resistance to *A. euteiches*. Secondly, we determined whether NO homeostasis could be modulated by N nutrition during the *M. truncatula*-*A. euteiches* interaction. We considered NO homeostasis as the maintenance of a functional NO concentration in a specific condition, through a balance between its biosynthesis (e.g., NR activity) and turnover pathways (e.g., interactions with GSH or O2− to form GSNO or ONOO−, respectively).

### MATERIALS AND METHODS

#### Plant Growth and Inoculation by *A. euteiches*

We used the *M. truncatula* Jemalong-A17 genotype. *M. truncatula* seeds were scarified according to Djébali et al. (2009). After stratification overnight at 4°C, they were germinated in phytochambers with 16 h light under 350 μmol m−2 s−1 photons at 23°C/8 h night at 21°C. One day after germination, the seedlings were transferred to 12 cm × 12 cm square Petri dishes containing modified M medium (Bécard and Fortin, 1988). This modified medium was sugar-free, enriched in phosphate (1.3 mM final concentration), and contained either 3.2 mM nitrate (complete medium) or no nitrate (NØ medium). The Petri dishes were sealed with parafilm and the roots were protected from light with aluminum foil, and then placed vertically in the culture chamber (16 h light under 350 μmol m−2 s−1 photons at 23°C/8 h night at 21°C) for 7 days. The strain *Aphanomyces euteiches* Drechs ATCC 201684 was used to inoculate the seeds one day after germination. Zoospores were produced as described in Rey et al. (2013), and each root was inoculated with 500 zoospores.
**Agrobacterium rhizogenes Root Transformation**

The pENTR4 vector carrying the MtNR1 or the MtNR2 fragment (Horchani et al., 2011) was recombined with the pK7GW1WG2d vector using LR clonase II enzyme mix (Invitrogen, France) to create RNA interference expression vectors. The MtGSNOR gene (*M. truncatula* Gene code Medtr7g099040) (1,143 bp) was amplified using *M. truncatula* cDNA as a template and the specific primers GSNOR-F 5′-AAAAAGCAGGCTTCACCATGCGATGAAAGGT-3′ and GSNOR-R 5′-AGAAAGCTGGGTGCAATGCAATGCAAGCACAC containing the corresponding attB recombination sites. The PCR product was recombined into the pDONR entry vector (Invitrogen) and checked by sequencing. The pDONR vector carrying the MtGSNOR gene was recombined with pK7WG2d plasmids1 to create the overexpression vector. The constructs pK7GW1WG2d-MtNR1-2/GFP (RNAi::MtNIA1/2) and pK7WG2d-MtGSNOR/GFP (35S::GSNOR) were introduced into *A. rhizogenes* strain Arqua1 (Quandt et al., 1993). *M. truncatula* plants were transformed with *A. rhizogenes* according to Boisson-Dernier et al. (2001). Control plants were transformed with *A. rhizogenes* containing the pK7GW1WG5D or the pK7WG2d empty vectors. Hairy roots were selected based on the fluorescent marker GFP 21 days after transformation.

**RNA Extraction, Reverse Transcription, and Quantitative PCR on Transformed Roots**

Total RNA was extracted from transformed roots using TRIzol® Reagent (Life Technologies) according to the manufacturer’s recommendations. To carry out the qPCR reaction, RNAs (0.5–1 µg) were reverse-transcribed in a final volume of 20 µL of the presence of RNasin (Promega, Charbonnières, France), and oligo(dT)15, with M-MLV reverse transcriptase (Promega, Charbonnières, France), as recommended by the manufacturer.

Quantitative PCR was performed on reverse-transcribed RNAs from four independent biological replicates per condition and from two independent plant cultures. Quantitative PCR reactions were performed in an ABI PRISM 7900 sequence detection system (Applied Biosystems®, Saint-Aubin, France), in a final volume of 15 µL containing Absolute SYBR green ROX Mix (Thermo Scientific, Surrey, UK), 0.3 µM of genespecific primers, and 5 µL of cDNA template diluted 60-fold. The reference gene used for normalization was *MtEF1a*. Relative expression was expressed as $2^{-\Delta\Delta Ct}$ test genes—reference gene. The primers used for the qPCR all displayed a high amplification efficiency (90–100%). They were the following:

- MtGSNORforward 5′-GTGACTCGGGGCTGTATGGAA-3′
- MtGSNOR reverse 5′-TGCAAGCACAACAGAAAGAC-3′
- MtNIA1 forward 5′-TGTTTCCACAGGCTTCTCCAGATA-3′
- MtNIA1 reverse 5′-CATAACAGGTCGTACTCAGCGA-3′

**Inoculation of Transformed Root Cultures with *A. euteiches***

Roots were cultured on Shb10 medium (Boisson-Dernier et al., 2001) and transferred on modified Fahraeus medium enriched in ammonitrate (1 mM NH₄NO₃) final) one day before inoculation. Inoculation of the root cultures with *A. euteiches* strain ATCC 201684 was carried out by adding 10 mL of an *A. euteiches* zoospore suspension containing 80,000 zoospores.mL⁻¹ in sterilized Volvic (Colditz et al., 2007) water. Zoospore production was initiated as described in Rey et al. (2013). Control root cultures were inoculated with 10 mL of sterile Volvic water. After 4 h of incubation in the dark, the zoospore solution was drained off the roots, and the Petri dishes were placed back into the growth room and left there for 7 days in the dark.

**Assessing Infection Levels by Enzyme-Linked Immunosorbent Assay (ELISA)**

Assessment of *A. euteiches* development in roots was performed by ELISA, using rabbit polyclonal serum raised against *A. euteiches*, and a mouse anti-rabbit IgG alkaline phosphatase conjugate as described by Sleczak et al. (1999), on protein extracts from roots from pooled plants. Alkaline phosphatase activity was monitored by recording the increase in absorbance at 405 nm for 2–3 h, and was expressed as the slope of the resulting curve per mg of root fresh weight.

**Hydrogen Peroxide Quantification**

H₂O₂ concentration was measured using Amplex Red®/peroxidase-coupled fluorescence assay adapted from Ashtamker et al. (2007). Roots were ground on ice and in the dark, in 1 mL of KRPG buffer (145 mM NaCl; 5.7 mM K₂HPO₄; 4.86 mM KCl; 0.54 mM CaCl₂; 1.22 mM MgSO₄; 5.5 mM glucose; pH 7.35) with 10 µM Amplex Red® and 0.2 U/mL of Horse Radish Peroxidase (HRP) per 100 mg of fresh weight. Catalase, an H₂O₂ scavenger, was used as a control. After 10 min of incubation at 4°C with catalase (1 unit/µL), 10 µM Amplex Red® and 0.2 U/mL of HRP were added to the samples. After centrifugation (10,000 x g, 15 min, 4°C), 100 µL of supernatant were used to quantify resorufin ($\lambda_{ex} = 560$ nm; $\lambda_{em} = 584$ nm) by spectrophotometry (Mithras, Berthold Technology). The relative fluorescence units were converted into µmol of H₂O₂ mg⁻¹ root fresh weight on the basis of a standard curve established from known concentrations of H₂O₂.

**Nitric Oxide and Peroxynitrite Quantification**

ONOO⁻ and NO concentrations were determined using A17 or transformed roots ground on ice and in the dark, with 1 mL of Tris-HCl (10 mM, pH 7.5), KCl (10 mM) buffer
with 5 μM aminophenyl fluorescein (APF) or 10 μM 4,5-diaminofluorescein (DAF), respectively, per 100 mg of fresh weight. Epicathechin, an ONOO− scavenger, was used as a control. After 10 min of incubation at 4°C with epicathechin (1 mM), APF was added to the samples at a final concentration of 5 μM. cPTIO, an NO scavenger, was used as a control. After 10 min of incubation at 4°C with cPTIO (500 μM), DAF was added to the samples at a final concentration of 10 μM.

After centrifugation (10,000×g, 15 min, 4°C), 100 μL of supernatant were used to quantify ONOO− or NO (λex = 485 nm; λem = 535 nm) by spectrofluorimetry (Mithras, Berthold Technology).

### S-nitrosothiol Quantification

S-nitrosothiol quantification was performed using the Saville–Griess assay (Gow et al., 2007). A17 roots or transformed roots were ground, on ice and in the dark, in extraction buffer (1 mL/100 mg of fresh weight, 0.1 M Tris-HCl, pH 7.5; 1 mM PMSF). After centrifugation (10,000×g, 15 min, 4°C), 100 μL of supernatant were incubated with 100 μL of buffer A (0.5 M HCl; 1% sulfanilamide) or 100 μL of buffer B (0.5 M HCl; 1% sulfanilamide; 0.2% HgCl2). After incubation (15 min at room temperature), 100 μL of Griess reagent[(0.5 M HCl; 0.02% N-(1-naphthyl)-ethylenediamine dihydrochloride] were added. After 15 min, SNOs were quantified by measuring absorbance at 540 nm. A standard curve was obtained using different concentrations of GSNO.

### Nitrate Determination

Nitrate determination was performed according to Miranda et al. (2001), based on the reduction of nitrate to nitrite by vanadium and colorimetric detection at 540 nm of nitrite in the presence of sulfanilamide and N-1-naphthylethylenediamine. Approximately 100 mg of 7-day-old plant roots were collected, flash-frozen in liquid N2, and ground into powder. Three hundred microliters of ultra-pure water were added to 20 mg of frozen sample, thoroughly vortexed, and incubated with occasional mixing for 15 min on ice. After centrifugation 15 min at 13,000 g, 5 min, 4°C, the supernatant was recovered and used for nitrate determination.

### Nitrate Reductase Activity Measurements

Transformed root samples were frozen in liquid nitrogen and ground using pestle and mortar. Extraction was performed in MOPS buffer (1 mL per 100 mg of fresh weight, 50 mM MOPS-KOH buffer, pH 7.6; 5 mM NaF; 1 μM Na2MoO4; 10 μM FAD; 1 μM leupeptin, 0.2 g/g FW polyvinylpolypyrrolidone; 2 mM β-mercaptoethanol; 5 mM EDTA). After centrifugation (20,000×g, 5 min, 4°C), the supernatant was used to measure NR activity. The reaction mixture consisted of 50 mM MOPS-KOH buffer, pH 7.6, containing 1 mM NaF; 10 mM KNO3, 0.17 mM NADH, and 5 mM EDTA. After incubation 15 min at 30°C, the reaction mixture was stopped by adding an equal volume of sulfanilamide (1% w/v in 3 N HCl) followed by N-naphthylethylenediamine dihydrochloride (0.02%, w/v), and the A540 was measured. A standard curve was obtained based on different concentrations of nitrite.

### GSNOR Activity Measurements

To measure GSNOR activity, roots were ground in liquid nitrogen and proteins were extracted in 50 mM Tris-HCl buffer, pH 8, 0.5 mM EDTA, and 1 mg/mL of a protease inhibitor cocktail (1 mL of buffer per 100 mg of fresh weight). GSNOR activity was assayed from the rate of NADH oxidation by measuring the decrease in absorbance at 340 nm at 25°C using 25 μg of proteins in a total volume of 200 μL of extraction buffer containing 350 μM NADH with or without 350 μM GSNO. GSNOR reductase activity was determined by subtracting NADH oxidation values in the absence of GSNO from values in the presence of GSNO. All samples were protected from light during the assay and tested for linearity. A standard curve was obtained using different concentrations of NADH.

### Statistical Analyses

Statistical analyses were performed using one- or two-way analysis of variance (ANOVA) followed by Fisher’s test. Data were considered as significantly different when p < 0.05.

### RESULTS AND DISCUSSION

**NO Homeostasis Participates in the M. truncatula Immune Response**

To investigate the putative role of NO homeostasis in the M. truncatula/A. euteiches interaction, roots were transformed to inactivate the NR-encoding MtNIA1/2 genes or to overexpress GSNOR-encoding genes. Quantification of gene transcripts in transformed roots using RT-qPCR confirmed that the two NIA genes were repressed (Figure 1A) while GSNOR was overexpressed (Figure 1B). To perform functional validation of the different constructs, we quantified NO and SNO levels in transformed roots. The two genetic manipulations modulated NO or SNO levels (Figure 1). SNO levels remained unchanged in RNAi::MtNIA1/2 roots as compared to the controls, whereas NO levels clearly decreased (Figure 1A). This was in accordance with the downregulation of NR, a major enzymatic source of NO. Conversely, NO levels in the 35S::GSNOR roots did not significantly change, but SNO significantly increased as compared to control roots (Figure 1B). This was surprising because in most previous experiments a negative correlation was described between SNO levels and GSNOR activity (Feechan et al., 2005; Rusterucci et al., 2007; Yun et al., 2011). However, it is interesting to note that in pea (a legume closely related to M. truncatula), higher SNO levels induced by wounding were correlated with higher GSNOR activity (Corpas et al., 2008).

We studied the impact of these genetic transformations on the M. truncatula/A. euteiches interaction. ELISA tests using antibodies raised against A. euteiches (Slezack et al., 1999) were performed to quantify the presence of the pathogen in roots. In RNAi::MtNIA1/2 roots (Figure 2A), A. euteiches colonization was significantly greater than in control transformed roots.

FIGURE 1 | Continued
Our results using GSNOR-transformed roots showed that pathogen levels were lower in GSNOR-overexpressing roots (Figure 2B) than in control transformed roots (Control LacZ roots). GSNOR could therefore be considered as a positive regulator of M. truncatula resistance to A. euteiches. Previous works already investigated the physiological roles of GSNOR in plant-pathogen interactions, using transgenic A. thaliana plants (Feechan et al., 2005; Rusterucci et al., 2007; Yun et al., 2011). Results are sometimes contradictory, as modulation of AtGSNOR expression enhanced or decreased plant disease resistance depending on the pathosystem. GSNOR could play a significant role in plant immunity because GSNO is considered as a mobile reservoir of NO, is more stable than NO, and is a transnitrosylation agent of proteins. The contrasted results obtained in our study with NR and GSNOR constructs could be attributed to the specific roles of the corresponding proteins in NO homeostasis. NR is involved in NO synthesis, whereas the primary role of GSNOR is to regulate GSNO contents. The recent results from Yun et al. (2016) confirm that GSNO and NO may play distinct roles in plant immunity by acting on different molecular targets. In addition, GSNOR indirectly affects NO, GSH, ROS, and total intracellular nitrosothiol (SNO) levels, indicating that GSNOR might be more globally involved in the regulation of the cell redox state (Espunya et al., 2006; Yun et al., 2011).

Nitric Oxide partly regulates N metabolism. Therefore we also investigated the effects of GSNOR overexpression on root NO$_3^-$ contents and NR activity in transformed roots. GSNOR overexpression increased basal NO$_3^-$ content and NR activity (Figures 3A,B). Modulation of N metabolism by GSNO and NO in A. thaliana has been described (Frungillo et al., 2014), and was explained by the effect of NO and GSNO on NR activity and on the expression of the AtNRT2.1 high-affinity NO$_3^-$ transporter gene. Similarly to our data, that study shows that GSNOR overexpression is correlated with higher NR activity and NO$_3^-$ content. Interestingly, we noted that pathogen colonization reduced NO$_3^-$ concentrations in roots by approximately 65%, suggesting an effect of A. euteiches on nitrate transport and/or NO$_3^-$ assimilation. Although we found a higher NO$_3^-$ content in 35S::GSNOR-infected roots than in control infected roots, the amplitude of the pathogen-induced decrease in NO$_3^-$ level was not impacted in 35S::GSNOR roots, suggesting that this process is independent of GSNO homeostasis. This reduced level of NO$_3^-$ is unlikely to result from consumption of NO$_3^-$ by the pathogen: data mining of the A. euteiches database revealed that no homologs of the NR, NIR, and NO$_3^-$ transporter (NRT2) genes were detected in the genome of this pathogen, confirming

**A** Transcript levels of MtNIA1 and MtNIA2 in RNAi::NIA1/2-transformed roots were compared to control transformed roots (control NR). SNO quantification using the Saville-Griess assay and NO quantification using the fluorophore DAF (10 µM). Control NR and RNAi::NIA1/2-transformed roots extracts were pre-incubated or not with 500 µM cPTIO as an NO scavenger. (B) Transcript levels of MtGSNOR in 35S::GSNOR-transformed roots were compared to control transformed roots (control LacZ). SNO quantification using the Saville-Griess assay and NO quantification using the fluorophore DAF (10 µM). Control LacZ and 35S::GSNOR-transformed roots extracts were pre-incubated or not with 500 µM cPTIO as an NO scavenger. Error bars indicate standard errors (n = 4 for transcripts and NO levels; n = 8 for SNO levels), and * indicates significant differences (p < 0.05).

**FIGURE 2 | Quantification of Aphanomyces euteiches in extracts from inoculated transformed roots.** RNAi::NIA1/2-transformed roots (A) and 35S::GSNOR-transformed roots (B) were extracted for ELISA tests. Roots were cultivated in vitro for 7 days on Fahraeus medium and then inoculated with A. euteiches. The background signal in non-inoculated roots was subtracted from the signal detected in inoculated roots. Error bars indicate standard errors (n = 4), and * indicates significant differences (p < 0.05). Data from one representative experiment out of four independent experiments.

(Control NR roots). These data reaffirm the role of the NR enzyme in the plant immune response. In A. thaliana, the NR-deficient double mutant (nia1 nia2) failed to exhibit a hypersensitive response and was hyper-susceptible to P. syringae (Modolo et al., 2006; Oliveira et al., 2009) and to the necrotrophic fungal pathogens Sclerotinia sclerotiorum or Botrytis cinerea (Perchepied et al., 2010; Rasul et al., 2012). Although these effects were attributed to the substantially reduced NO levels in this mutant, a side effect of N metabolism on plant defense cannot be excluded as NR stands at the crossroads between N metabolism and NO production.
earlier observations that $\text{NO}_3^-$ is unfavorable for \textit{A. euteiches} development (Huber and Watson, 1974). Alternatively, we cannot exclude that the decreased $\text{NO}_3^-$ content in infected roots could be due to nitrate leakage from the roots related to developing necrosis.

**Effect of N Nutrition on NO/ $\text{H}_2\text{O}_2$/ONOO$^-$/ Accumulation and SNO Contents**

To analyze the role of N availability on NO, $\text{H}_2\text{O}_2$, and ONOO$^-$ accumulation, \textit{M. truncatula} plants were cultivated in complete medium or $\text{NO}_3^-$-deficient medium (NO), and inoculated or not with \textit{A. euteiches}. The NO scavenger cPTIO and the ONOO$^-$ scavenger epicatechin were used as controls to check the specificity of the fluorescence probes. We observed that $\text{NO}_3^-$ deficiency caused a significant increase in ONOO$^-$ content on NO medium (Figure 4C), whereas NO and $\text{H}_2\text{O}_2$ levels decreased (Figures 4A,B), highlighting a link between $\text{NO}_3^-$ content and production of these reactive species. A clear effect of pathogen colonization was only evidenced for $\text{H}_2\text{O}_2$ contents (Figure 4A), and this increase was abolish on NO. Surprisingly, although NO production is considered as a common response to pathogens, no increase in NO levels was detected in response to \textit{A. euteiches} (Figure 4B). More generally, whereas NO, ROS, or ONOO$^-$ production has been widely described in response to pathogens, the literature does not give a clear picture of the cross-talks between these molecules. For instance, we observed a negative correlation between NO and ONOO$^-$ contents in response to $\text{NO}_3^-$ deficiency, but in other models high NO levels are often correlated with high ONOO$^-$ levels (Abramowski et al., 2015; Kulik et al., 2015). These conflicting observations raise some questions. Are these discrepancies due to plant models or due to the difficulty in measuring and precisely localizing these molecules? Differences in the stability of these molecules or their specific scavenging by plants during pathogen attack could explain why we did not detect changes in ONOO$^-$ or NO levels in response to \textit{A. euteiches}. Moreover, NO could also be used by the pathogen to activate its own metabolism, an important step in plant infection by fungi (Sedlářová et al., 2016).

We also measured root SNO levels and GSNOR activity in the biological conditions of interest. Root SNO contents, determined using the Saville–Griess method, significantly increased on NO medium as compared to the complete medium (Figure 4D). In response to \textit{A. euteiches}, no significant change in SNO levels was highlighted (Figure 4D). Therefore, on NO medium, the SNO content evolved in an opposite way to the NO content, similarly to the ONOO$^-$ content. This result is in accordance with results reported in \textit{Helianthus annuus} (Chaki et al., 2011), and can be attributed to the fact that NO is the source for ONOO$^-$ and SNO. By contrast, a high NO content can be correlated with a high SNO content when plants are grown on culture medium containing $\text{NO}_3^-$ (Abramowski et al., 2015; Pietrowska et al., 2015). Our data also suggest that $\text{NO}_3^-$ nutrition impacts the overall balance between NO, ONOO$^-$, and SNO. Regarding GSNOR, no changes in its activity was detected upon inoculation, in line with the absence of change in SNO levels in infected roots. In the roots of plants cultivated on NO (Figure 5), higher GSNOR activity was correlated with higher SNO levels, confirming the positive correlation between GSNOR activity and SNO levels observed in 35S::GSNOR-transformed \textit{Medicago} roots (Figure 1) and in pea, a closely related legume (Corpas et al., 2008). The positive or negative correlation between GSNOR activity and SNO levels or between NO and SNO levels depending on plant species and experimental conditions can be explained by several hypotheses. The SNO level is regulated through nitrosylation and denitrosylation; GSNOR, by controlling the level of GSNO, indirectly affects the level of S-nitrosylation. However, the TRX (thioredoxin)/NTR (NADPH-dependent TRX reductase) enzymatic system also controls S-nitrosylation (Kneeshaw et al., 2014). Interestingly, these activities were also identified in roots and activated by NO, leading to denitrosylation of specific proteins (Correa-Aragunde et al., 2015). Thus, these results, together with our study, illustrate the complex relationships...

FIGURE 4 | H$_2$O$_2$, NO, ONOO$^-$, and SNO quantification in Medicago truncatula roots 7 dpi. M. truncatula was cultivated on complete medium or NØ medium, and roots were harvested 7 days after inoculation with A. euteiches and used to detect H$_2$O$_2$, NO, and ONOO$^-$ concentrations using fluorescent probes, and SNO concentrations using the Saville–Griess assay. (A) H$_2$O$_2$ quantification using 10 µM Amplex Red® fluorophore and 0.2 U/mL of peroxidase. Catalase (1 U/µL), used as an H$_2$O$_2$ scavenger, abolished Amplex Red® fluorescence. (B) NO quantification using the fluorophore DAF (10 µM). Root extracts were pre-incubated or not with 500 µM cPTIO as an NO scavenger. (C) ONOO$^-$ quantification using the fluorophore APF (5 µM). Root extracts were pre-incubated or not with 1 mM of the ONOO$^-$ scavenger epicatechin. (D) SNO quantification by the Saville–Griess assay. Error bars indicate standard errors (n = 4 for A–C; n = 14 for D), and letters indicate significant differences (p < 0.05). Data from one representative experiment out of three independent experiments for H$_2$O$_2$, NO, and ONOO$^-$ concentrations, and data corresponding to two independent experiments pooled together for SNO concentrations. RFU, relative fluorescence units.

between NO production/GSNOR activity and total SNO levels. Abiotic stresses also increase GSNOR activity (Kubienova et al., 2014), and this appears to be the case for M. truncatula plants under NO$_3^-$ deficiency. Higher GSNOR activity in N-deprived roots (Figure 5) could lead to a physiological state inducing higher resistance to A. euteiches, as observed in the 3SS::GSNOR-transformed roots (Figure 2B). This could partly explain the enhanced resistance to this oomycete on NO medium despite the low levels of NO in the roots. Thus, altogether our data highlight the possible positive and non-redundant roles of NO (Figures 1A and 2A) and SNO (Figures 1B, 2B, and 4D) in mediating M. truncatula resistance to A. euteiches.

CONCLUSION AND NEW HYPOTHESES

The results obtained in the present study are summarized in Figure 6. We have demonstrated, using transformed roots affected in genes involved in NO synthesis (NIA genes) and turnover (GSNOR gene), that deregulation of NO homeostasis has an effect on M. truncatula resistance against A. euteiches, as observed in other pathosystems (1). In addition, it appears that the modulation of NO homeostasis (through GSNOR overexpression) impacts NR activity and NO$_3^-$content, indicating possibly an effect of GSNOR (or GSNO) on basal NO$_3^-$ transport/assimilation
and confirming the results of Frungillo et al. (2014) (2). In return, NO$_3^-$ availability in the medium can affect NO homeostasis by modulating ROS/RNS/NO contents and their balance (3). Finally, infection by *A. euteiches* decreases root NO$_3^-$ content (4) and induces higher ROS levels (5). Altogether these results highlight the close interplay occurring between N nutrition and NO homeostasis as well as the involvement of NO in the modulation of plant resistance by N nutrition.

Future work should take into account the role of N availability on NO-mediated plant molecular responses. Thus, the study of the specific role of GSNO in this process through the identification S-nitrosylated/denitrosylated proteins under different N availability conditions and N sources seems promising. A focus will be made on proteins involved in the plant immune response (1), but also on the feedback regulation of N metabolism by NO because NO could control NO$_3^-$ availability and therefore plant resistance (2) (Figure 6). Investigations using foliar pathogens and other plant models will lead to a possible generalization of this phenomenon. More generally, plant N use efficiency can be affected by NO since NO controls not only N metabolism but also plant root growth and architecture changes in response to NO$_3^-$ (Manoli et al., 2014; Sun et al., 2015). Recent data show that plant N use efficiency and N-induced susceptibility to pathogens may be linked (Ballini et al., 2013). Consequently future studies should also focus on candidate proteins involved in root development. Finally, experiments conducted with plant genotypes differing in their resistance levels will permit to study the quantitative effect of NO/ROS production on plant defense.

**AUTHOR CONTRIBUTIONS**

ET, H-NT, ABo, and SJ conceived and designed the research; ET, H-NT, CF, ABo, and ABe carried out the experiments and analysis/interpretation of data; ET, H-NT, DW, and SJ wrote the manuscript. All authors contributed to the discussion and approved the final manuscript.

**FUNDING**

ET was funded by a Ph.D. contract (2013–2032) from the Ministère de l’Enseignement Supérieur et de la Recherche. This work was supported by a grant from AgroSup Dijon and the Conseil Régional de Bourgogne (PARI8).

**ACKNOWLEDGMENTS**

We would like to thank N. Pauly for practical advice on *M. truncatula* root transformation, E. Gaulin, A. Nars, and C. Jacquet for providing the *A. euteiches* strain Drechs. ATCC 201684, and advice on the pathosystem, and E. Dumas-Gaudot for gift of the polyclonal antibody directed against *A. euteiches*.
