We present an analogy between the one dimensional Poisson equation in inhomogeneous media and the Dirac equation in one space dimension with a Lorentz scalar potential for zero energy. We illustrate how the zero energy state in the Jackiw-Rebbi model can be implemented in a simple one dimensional electrostatic setting by using an inhomogeneous electric permittivity and an infinite charged sheet. Our approach provides a novel insight into the Jackiw-Rebbi zero energy state and provides a helpful view in teaching this important quantum field theory model using basic electrostatics.

I. INTRODUCTION

The Dirac equation is one of the fundamental equations in theoretical physics that accounts fully for special relativity in the context of quantum mechanics for elementary spin-1/2 particles.1 The Dirac equation plays a key role to many exotic physical phenomena such as graphene,2 topological insulators3 and superconductors.1 These systems proved to be ideal testing grounds for theories of the coexistence of quantum and relativistic effects in condensed matter physics. Recently, a significant number of studies has addressed the problem of simulating relativistic quantum mechanics using different physical platforms such as optical structures,4 metamaterials5 and ion traps.6 These studies are based on the mathematical analogies found between different physical theories which provides a way to explore at a macroscopic level many quantum phenomena which are currently inaccessible in microscopic quantum systems. Among the wide variety of quantum-classical analogies investigated so far it appears that the most fruitful one is given by the analogy between optics with quantum phenomena due naturally to the duality between matter and optical waves. The study of quantum-optical analogies is based on the formal similarity between the paraxial optical wave equation in dielectric media and the single particle Schrodinger equation.7 Among the wide variety of quantum-optical analogies we can mention the Bloch oscillations and Zener tunneling, dynamic localization, Anderson localization, quantum Zeno effect, Rabi flopping and coherent population trapping. All these progress has led to the area of research of how relativistic quantum systems can be mimic by optical waves. More recently, optical systems governed by the relativistic Dirac equation have been investigated experimentally such as Klein Tunneling, Zitterbewegung and the Jackiw-Rebbi model.

The purpose of this article is to demonstrate that electrostatics can provide a laboratory tool where physical phenomena described by the Dirac equation can be explore. In particular, we demonstrate that the Poisson equation in one dimensional inhomogeneous media can be mapped into the zero energy state of the Dirac equation in one dimension with a Lorentz scalar potential. By tailoring the electric permittivity we propose an electrostatic experiment that simulates a historically important relativistic model known as the Jackiw-Rebbi model.10 Since the derivation of this important model many useful variations of the Jackiw-Rebbi model have been investigated such as the Ramajaran-Bell model11 the massive Jackiw-Rebbi model12 the coupled fermion-kink model13 and the Jackiw-Rebbi model in distinct kinklike backgrounds.14 The article is organized as follows. First we will start with a brief review of the Jackiw-Rebbi model and how one can obtain the zero energy state of the JR model. Then we will show how the Poisson equation can be mapped into a Dirac-like equation, and illustrate how the zero energy state in the Jackiw-Rebbi model can be implemented in a simple one dimensional electrostatic setting by using an infinite charged sheet separating two different media. The conclusions are summarized in the last section.

II. JACKIW-REBBI MODEL IN ONE DIMENSION

The Jackiw-Rebbi model describes a one dimensional Dirac field coupled to a static background soliton field and is known as one of the earliest theoretical description of a topological insulator where the zero energy mode can be understood as the edge state. In particular, the Jackiw-Rebbi model has been studied by Su, Shrieffer and Heeger in the continuum limit of polyacetylene.15 The one dimensional Dirac equation in the presence of an external field \( \varphi(x) \) and with \( \hbar = c = 1 \) is given by

\[
\hat{H}_D \Psi(x) = [\sigma_y \hat{\rho} + \sigma_x \varphi(x)] \Psi(x) = \mathcal{E} \Psi(x)
\]

(1)

where

\[
\sigma_y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad \Psi = \begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix}.
\]

(2)

We use the Pauli matrices \( \sigma_x \) and \( \sigma_y \) in order to have a real two component spinor \( \Psi(x) \). From eq. (2) it follows that the Dirac Hamiltonian possesses a chiral symmetry defined by the operator \( \sigma_z \), which anticommutes with the Dirac Hamiltonian, i.e. \( \{ \hat{H}_D, \sigma_z \} = 0 \). The \textit{chiral} symmetry implies that eigenstates
come in pairs with positive and negative energy ±E, respectively. It is possible however for an eigenstate to be its own partner for E = 0, if this is the case then the state is topologically protected. The resulting zero energy state is protected by the topology of the scalar field, whose existence is guaranteed by the index theorem, which is localised around the soliton\footnote{The precise formulation of the external scalar potential is not important as long as it asymptotically approaches an opposite sign at x → ±∞. The wave function may change corresponding to a particular form of the external scalar potential, but the existence of the zero energy state is determined solely by the fact that the mass is positive on one side and negative on the other. Therefore, the solution is very robust against the external scalar potential.}

The solution of the Dirac equation at exactly zero energy for the scalar field given by eq. (3) is a simplification of the Jackiw-Rebbi model first proposed by Rajaraman-Bell\footnote{The Jackiw-Rebbi model uses φ(x) = m tanh(λx) for the external scalar field, with m > 0 and λ > 0. For simplicity we will consider a external scalar field given by φ(x) = m x/|x|} \footnote{Forming a domain wall at x = 0 where φ(x = 0) = 0. The scalar field given by eq. (3) is a simplification of the Jackiw-Rebbi model first proposed by Rajaraman-Bell\footnote{The precise formulation of the external scalar potential is not important as long as it asymptotically approaches an opposite sign at x → ±∞. The wave function may change corresponding to a particular form of the external scalar potential, but the existence of the zero energy state is determined solely by the fact that the mass is positive on one side and negative on the other. Therefore, the solution is very robust against the external scalar potential.}}

\[ \begin{pmatrix} 0 & -\partial_x + \varphi(x) \\ \partial_x + \varphi(x) & 0 \end{pmatrix} \begin{pmatrix} \psi_1(x) \\ \psi_2(x) \end{pmatrix} = 0 \] \footnote{The solution of the Dirac equation at exactly zero energy for the scalar field given by eq. (3) is obtained by solving the following equation}

which gives

\[ \psi_i = C_\pm \exp \left[ \mp m|x| \right], \quad \text{for} \ i = 1, 2. \] \footnote{where C± is a normalization constant and the double sign in eq. (5) is −(+) for i = 1(2). Note that ψ1,2 cannot be both normalized. If we impose that lim x→±∞ ψi(x) → 0 we need to make C± = 0 in order to have a properly normalized state. In Fig. 4 we show the wave function for the zero energy state of the Jackiw-Rebbi model.}

III. ELECTROSTATIC ANALOG OF THE JACKIW-REBBI MODEL

In this section we show that the zero energy Jackiw-Rebbi state can be generated at the interface of two dielectric materials separated by a infinite charged sheet. The use of infinite charged sheets for emulating physical systems has been used extensively in the past for a wide range of applications such as a simple parallel plate capacitor\footnote{The precise formulation of the external scalar potential is not important as long as it asymptotically approaches an opposite sign at x → ±∞. The wave function may change corresponding to a particular form of the external scalar potential, but the existence of the zero energy state is determined solely by the fact that the mass is positive on one side and negative on the other. Therefore, the solution is very robust against the external scalar potential.} or the study of the one dimensional Coulomb gas\footnote{The precise formulation of the external scalar potential is not important as long as it asymptotically approaches an opposite sign at x → ±∞. The wave function may change corresponding to a particular form of the external scalar potential, but the existence of the zero energy state is determined solely by the fact that the mass is positive on one side and negative on the other. Therefore, the solution is very robust against the external scalar potential.}. Since we will be working with a planar charge distribution we will consider only the one dimensional Poisson equation with an inhomogeneous electric permittivity, i.e. ϵ(x), which is given by

\[ \frac{d}{dx} \left( \epsilon(x) \frac{dV}{dx} \right) = -\rho(x), \] \footnote{The solution of the Dirac equation at exactly zero energy for the scalar field given by eq. (3) is a simplification of the Jackiw-Rebbi model first proposed by Rajaraman-Bell\footnote{The precise formulation of the external scalar potential is not important as long as it asymptotically approaches an opposite sign at x → ±∞. The wave function may change corresponding to a particular form of the external scalar potential, but the existence of the zero energy state is determined solely by the fact that the mass is positive on one side and negative on the other. Therefore, the solution is very robust against the external scalar potential.}}

where V(x) is the electrostatic potential and ρ(x) is the volume charge distribution. Expanding the left hand side of eq. (6) and multiplying by 1/ε we have

\[ \frac{d^2V}{dx^2} + \epsilon' \frac{dV}{dx} = -\frac{\rho}{\epsilon}, \] \footnote{The solution of the Dirac equation at exactly zero energy for the scalar field given by eq. (3) is a simplification of the Jackiw-Rebbi model first proposed by Rajaraman-Bell\footnote{The precise formulation of the external scalar potential is not important as long as it asymptotically approaches an opposite sign at x → ±∞. The wave function may change corresponding to a particular form of the external scalar potential, but the existence of the zero energy state is determined solely by the fact that the mass is positive on one side and negative on the other. Therefore, the solution is very robust against the external scalar potential.}}

where ε′ represents the total derivative with respect to the space coordinate x. Let us now make the following transformation

\[ V(x) = V_0 \ln \left( \psi_1(x)/A \right), \] \footnote{The solution of the Dirac equation at exactly zero energy for the scalar field given by eq. (3) is a simplification of the Jackiw-Rebbi model first proposed by Rajaraman-Bell\footnote{The precise formulation of the external scalar potential is not important as long as it asymptotically approaches an opposite sign at x → ±∞. The wave function may change corresponding to a particular form of the external scalar potential, but the existence of the zero energy state is determined solely by the fact that the mass is positive on one side and negative on the other. Therefore, the solution is very robust against the external scalar potential.}}

where V0 and A are constants to ensure dimensional consistency, and ψ1(x) is an arbitrary function. Substituting eq. (8) into eq. (7) we have

\[ \frac{V_0}{\psi_1} \frac{\psi_1''}{\psi_1} - \epsilon' E_x - \frac{1}{V_0} E_x^2 = -\frac{\rho}{\epsilon}, \] \footnote{The solution of the Dirac equation at exactly zero energy for the scalar field given by eq. (3) is a simplification of the Jackiw-Rebbi model first proposed by Rajaraman-Bell\footnote{The precise formulation of the external scalar potential is not important as long as it asymptotically approaches an opposite sign at x → ±∞. The wave function may change corresponding to a particular form of the external scalar potential, but the existence of the zero energy state is determined solely by the fact that the mass is positive on one side and negative on the other. Therefore, the solution is very robust against the external scalar potential.}}

where we have used the identity E_x = −dV/dx. If we use eq. (6) in the right hand side of eq. (9) we end up with the following equation

\[ \frac{V_0}{\psi_1} \frac{\psi_1''}{\psi_1} - \frac{dE_x}{dx} - \frac{1}{V_0} E_x^2 = 0, \] \footnote{The solution of the Dirac equation at exactly zero energy for the scalar field given by eq. (3) is a simplification of the Jackiw-Rebbi model first proposed by Rajaraman-Bell\footnote{The precise formulation of the external scalar potential is not important as long as it asymptotically approaches an opposite sign at x → ±∞. The wave function may change corresponding to a particular form of the external scalar potential, but the existence of the zero energy state is determined solely by the fact that the mass is positive on one side and negative on the other. Therefore, the solution is very robust against the external scalar potential.}}
We can easily construct the zero energy mode by setting \( \psi \) in eq. (12) and solving for the uncoupled first order differential equations (16) given by one of the authors (GG). The relation between Poisson’s equation and Schrödinger equation in one dimension has been pointed out before by one of the authors (GG).

Interestingly, the electrostatic field given by eq. (16) has the same form as the external scalar field given by eq. (13) that allows the existence of the zero energy state in the JR model. The electrostatic potential for the electric field given by eq. (16) is

\[
V(x) = -\int_0^x E_x(x)\,dx = \begin{cases} \frac{\sigma}{\epsilon_1}, & \text{for } x > 0 \\ \frac{\epsilon_2}{\sigma}, & \text{for } x < 0 \end{cases}
\]

FIG. 3: The figure shows the electrostatic Jackiw-Rebbi zero energy mode given by Eq. (18) for the following values \( \sigma = V_0 = 1, \epsilon_1 = 1 \) and \( \epsilon_2 = 2 \).

Using eq. (15) we see that we need to set \( C_+ = 0 \) in order to make the two-component spinor normalizable. Therefore, the normalized wave function for the zero mode is given by

\[
\Psi(x) = \sqrt{\frac{\sigma}{V_0(\epsilon_1 + \epsilon_2)}} \begin{pmatrix} e^{V(x)/V_0} \\ 0 \end{pmatrix}.
\]

In Fig. 3, we show the electrostatic zero energy wave function for the Jackiw-Rebbi model, the wave function dominantly distributes near the interface \( x = 0 \) and decays exponentially away. The solution given in eq. (18) for \( \epsilon_1 = \epsilon_2 \) is the same as the Jackiw-Rebbi zero energy state.

### IV. CONCLUSIONS

In conclusion we have shown that the Poisson equation in one dimensional inhomogeneous media can be used to simulate the Jackiw-Rebbi model in one space dimension for the zero energy state. In particular, we demonstrate how the zero energy state of the Jackiw-Rebbi model can be implemented in an electrostatic set up with an infinite charged sheet that separates two different media. Based on these findings, we have introduced an electrostatic platform for realizing the zero energy state of the Jackiw-Rebbi model which allows one to probe in the laboratory.
