Posttraumatic infections can occur in orthopedic trauma patients, especially in open fractures. Rapid and accurate identification of pathogens in orthopedic trauma is important for clinical diagnosis and antimicrobial treatment. Matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS) has been successfully used for first-line identification of pathogens grown on culture plates. However, for direct analysis of liquid clinical specimens, pre-purification of the sample is necessary. Herein, we investigated the feasibility of coupling Fc-MBL@Fe3O4 enrichment with MALDI-TOF MS profiling in the identification of pathogens in liquid-cultured samples. This method is successfully used for the identification of pathogens in a patient with an open-leg fracture obtained at sea. Pathogens were enriched by Fc-MBL@Fe3O4 from briefly pre-cultured liquid media and identified by MALDI-TOF MS. We identified an opportunistic pathogen, Vibrio alginolyticus, which is uncommon in clinical orthopedic trauma infection but exists widely in the sea. Therefore, combining Fc-MBL@Fe3O4 enrichment and MALDI-TOF MS profiling has great potential for direct identification of microbes in clinical samples.

Keywords: MALDI-TOF MS, orthopedic trauma infection, magnetic enrichment, pathogen identification, Vibrio alginolyticus

INTRODUCTION

Orthopedic traumas are complex and diverse. Serious wounds are always difficult to debride; especially, when complicated fractures are combined, the surgical treatment is often required (Morgenstern et al., 2018; Tuon et al., 2019). Posttraumatic infections can occur in orthopedic trauma patients when it is not treated in a timely manner or after surgical treatment (Arnold et al., 2013; Yun et al., 2016; Backes et al., 2018). Rapid identification of pathogenic bacteria in orthopedic trauma, especially open fractures, guides the clinical diagnosis and antimicrobial treatment (Yun et al., 2016; Patrulie et al., 2020). Thus, superficial wound swabs or deep fluid samples are always sent to the clinical microbiology lab for bacterial identification.
The current standard of bacterial identification in hospitals continues to rely on culture-based biochemical testing, which may take days to complete (Varadi et al., 2017; Backes et al., 2018). Moreover, culture-based methods suffer increasing skepticism about their sensitivity and accuracy (Rhoads et al., 2012; Firoozabadi et al., 2015). Molecular methods that rely on the analysis of genomic markers, such as ribosomal RNA sequencing, have better sensitivity and accuracy for pathogen identification (Rhoads et al., 2012). However, molecular diagnostic methods have high cost and require sophisticated expertise (Woo et al., 2008; Segawa et al., 2014). In recent years, matrix-assisted laser desorption/ionization-time-of-flight mass spectrometry (MALDI-TOF MS) has been introduced into clinical microbiology laboratories. Due to the specificity, speed of analysis, and low cost of consumables, MALDI-TOF MS has been widely acclaimed for clinical bacterial identification (Singhal et al., 2015). MALDI-TOF MS can be compared to the MS database to identify the bacterial ribosomal proteins in the analysis of clinical bacteria, fungi, mycobacteria, and Nocardia (Feng et al., 2020). Nevertheless, the single colonies are always needed for this method. Clinical samples or liquid cultured samples are inoculated on solid culture plate to grow single colonies for identification of clinical bacteria, fungi, mycobacteria, and Nocardia. For direct analysis of bacteria in liquid clinical samples, the pre-purification steps are mandatory. Since approximately 10⁵ CFU of bacteria are needed for successful identification, direct analysis of bacteria in clinical samples seems only possible for urine samples (Zboromyrska et al., 2016). Utilizing of liquid cultures has increased the sensitivity and decreased the turn-around time of bacterial culture, especially for samples with low bacterial loads. Hence, development of pre-purification methods for liquid-cultured bacterial sample is sorely needed.

Functionalized magnetic nanoparticles (MNPs) have been developed to capture bacteria and simplify the purification processes due to its large ratio of surface area to volume, ease of operation, and good biocompatibility (Liébana et al., 2009; Cheng et al., 2016; Zhu et al., 2016; Yi et al., 2018; Nemr et al., 2019). Specific aptamers and antibodies were conjugated with MNPs to enrich certain bacteria or part of microbes from suspension (Liébana et al., 2009; Cheng et al., 2016; Zhu et al., 2016; Yi et al., 2018; Nemr et al., 2019). Mannose-binding lectin (MBL) is an important opsonin component of the lectin pathway associated with innate immunity, which can recognize and bind carbohydrates on the surfaces of different bacteria, fungi, and viruses in a calcium-dependent manner (Takahashi and Ezekowitz, 2005). Ingber et al. genetically engineered a new version of MBL by fusing the carbohydrate recognition region of MBL to the flexible neck of the Fc portion of IgG1, which conjugated with MNPs and was used to cleanse septic blood or enrich bacteria in clinical samples (Kang et al., 2014; Bicart-See et al., 2016). These studies indicated that Fc-MBL has binding capability for a wide range of microbes, which prompted us to utilize Fc-MBL@Fe₃O₄ to enrich bacteria and combine with the MALDI-TOF MS identification.

Herein, we investigated the feasibility of the MALDI-TOF MS profiling coupled with Fc-MBL@Fe₃O₄ enrichment for identification of bacteria in liquid culture media (Scheme 1). After the verification, the application of this method in real case was explored. A patient obtained an open fracture at sea and did not acquire treatment for more than 20 h due to diagnostic limitations. Considering that the patient was injured at sea, uncommon species of bacteria may have adhered to the wound; we attempt to use Fc-MBL@Fe₃O₄ enrichment coupled with MALDI-TOF MS identification. A wound swab and fluid were short-term cultured on liquid media and analyzed by the proposed method, wherein Vibrio alginolyticus was identified. These results show that these pathogen identification procedures are more rapid than traditional methods and beneficial for clinical treatment of patients.

**MATERIAL AND METHODS**

**Patient**

A 56-year-old male patient was crushed while working on the boats, and his right calf was stressed, accompanied by skin lacerations and bleeding. He had an open wound approximately 6 × 15 cm in the lower part of the right calf, and the fractured end was exposed. Because the patient was unable to acquire clinical treatment at sea, the wound was simply bandaged to stop the bleeding. After more than 20 h, the patient was sent to the hospital and diagnosed with open comminuted fracture of the lower right tibia and fibula. This study was approved by the Ethics Committee of Ningbo No. 6 Hospital.

**Chemicals and Instruments**

α-Cyano-4-hydroxycinnamonic acid (CHCA), formic acid, and acetonitrile (ACN) were purchased from Merck (Darmstadt, Germany). Trifluoroacetic acid (TFA) was obtained from Shanghai Macklin Biochemical Technology Co., Ltd. (Shanghai, China). Tryptone soybean agar (TSA) and Luria–Bertani (LB) broth were purchased from Beijing Land Bridge Technology Co., Ltd (Beijing, China). The functionalized MNPs (Fc-MBL@Fe₃O₄) were synthesized as in our previous study (Sun et al., 2021). The detailed synthesis procedures and characterization results are presented in the Supporting Information.

The mass spectra for the verification of method were obtained by Autoflex max TOF/TOF mass spectrometer (Bruker Daltonics, Germany) with a pulsed Nd:YAG laser (355 nm) in a linear positive mode. The acceleration voltage was set at 20 kV, each spectrum was acquired by 1000 laser shots, and the laser intensity was regulated to ensure a good signal-to-noise ratio. MALDI-TOF MS identification was carried out using an M-Discover 100 mass spectrometer (Zhuhai Meihua Medical Technology Co., Ltd, China) in a linear positive mode with the m/z range 2–20 KDa. The mass spectra were calibrated by Escherichia coli (ATCC 8739) according to the manufacturer’s
instructions. MicroCtrl 1.0 software was used to acquire the spectra and for real-time interpretation and identification; the raw spectra were processed by smoothing, baseline removal, and peak-picking, and the processed spectra were compared with the reference spectra in the database by using the pattern-matching algorithm of the software. The scores that ranged from 0.00 to 3.00 were calculated based on the correlation between the two spectra. According to the manufacturer, a score >2.0 is considered reliable in the species level, a score 1.7–2.0 indicates identification in the genus level, and a score <1.7 indicates unreliable result. Transmission electron microscopy (TEM) images were obtained by microscope JEOL JEM 2100 (Japan) at 200 kV.

Sample Preparation and MNP Enrichment
For verification of the method, the standard bacteria strains (S. aureus, ATCC 25923; K. pneumoniae, CICC 21519) were inoculated on the TSA solid plate, and the single colonies were adjusted to certain concentrations by measuring the absorbance at 600 nm using UV–vis absorption spectroscopy. For the enrichment efficiency of Fc-MBL@Fe3O4, 1000 or 100 CFUs of S. aureus and 10 μl of Fc-MBL@Fe3O4 solution (10 mg/ml) were added in 30 μl Tris-HCl buffer (0.1 mM, pH 7.4) containing 10 mM CaCl2 and 0.05% Tween-20 and incubated at 37°C for 15 min with shaking. After magnetic enrichment, the pellets were washed twice with 100 μl of water. The bacterial proteins were extracted as above description. For the verification, the subcultured liquid samples were grown on the TSA solid medium for 24 h, and the bacterial colonies were identified by MALDI-TOF MS.

MALDI-TOF MS Analysis
The bacterial protein solution (1 μl) extracted from MNPs was deposited on a MALDI target plate. Then, CHCA matrix (10 mg/ml in ACN/H2O (v/v = 1/1) containing 2% TFA) was deposited on the sample spot after drying. For analysis of bacteria grown on the solid TSA medium, the standard extraction method was used (Matsuda et al., 2012). Briefly, a 1-μl loop of bacteria was suspended in 300 μl H2O, and 900 μl ethanol was added. After vigorous vortex, the mixture was centrifuged at 12,000 rpm for 5 min. The supernatant was discarded, and 30 μl of 70% formic acid was added to the pellets and thoroughly mixed. Next, 30 μl of ACN was added, and the resulting solution was centrifuged again at 12,000 rpm for 5 min. One microliter of supernatant was deposited on the MALDI target plate and dried at room temperature. Finally, 1 μl of CHCA matrix was placed on the sample spots and left to dry.

Clinical Routine Pathogen Identification
The clinical samples were inoculated on the Columbia blood agar, Sabouraud’s fungus agar, and anaerobic medium plate in a sterile manner and incubated in 35 ± 2°C for 24–48 h in clinical microbiology laboratory. The bacteria grown on the solid media were subjected to Gram staining, and the isolates were identified using a VITEK2-Compact automatic bacterial identification instrument (Biomérieux) in accordance with the manufacturer’s instructions.

RESULTS AND DISCUSSION
Feasibility of the Proposed Method
The workflow of the proposed method was illustrated in Scheme 1. The pathogens in liquid clinical samples or short-term–cultured liquid samples were captured by Fc-MBL@
the enriched bacteria were extracted by formic acid from Fe₃O₄ and subjected to MALDI-TOF MS identification. Before application in real case, we investigated the feasibility of the method. A common pathogen in orthopedic infection, *Staphylococcus aureus* (*S. aureus*), was selected as model to verify the method. The synthesis and characterization of Fe₃O₄ were presented in supporting information. The TEM images of Fe₃O₄ binding to *S. aureus* are shown in Figure 1A, which indicated the binding capability of Fe₃O₄ to *S. aureus*. Next, the capture efficiency of Fe₃O₄ was evaluated by the plate-counting method. Briefly, the different amounts of *S. aureus* suspension were enriched by Fe₃O₄; the bacteria in original solution, captured by Fe₃O₄, and the supernatant were inoculated on the TSA plate in parallel, and the results are shown in Figure 1B. It can be seen that bacteria were almost captured completely by Fe₃O₄. Then, the different amounts (10⁸/10⁷/10⁶/10⁵ CFU) of *S. aureus* in 1 ml buffer solution were enriched by Fe₃O₄ and identified by MALDI-TOF MS. As shown in Figure 2, the spectra of ≥10⁶ CFU of bacteria in buffer enriched by Fe₃O₄ show similar profiles with the standard spectrum of pure bacteria. It is should be noted that approximately ~10⁶ CFU are needed on the target plate for successful bacteria identification with MALDI-TOF MS (Segawa et al., 2014), which means the concentration of 10⁶ CFU/ml is needed, wherein 1 µl of bacteria suspension is deposited on the target plate. In this method, the enriched pellets were eluted by 10 µl solution (5 µl 70% formic acid +5 µl ACN), and the 1 µl of solution is deposited on the target plate. Thus, the results are rational that 10⁶ CFU of bacteria in 1 ml buffer solution could be detected successfully by the proposed method. Furthermore, *S. aureus* and another bacteria *Klebsiella pneumoniae* (*K. pneumoniae*) were spiked in LB liquid media at 10⁸ CFU/ml (the concentration of clinical positive cultures is ~10⁶ CFU/ml). The 100 µl of liquid bacterial cultures were enriched by Fe₃O₄ and analyzed by MALDI-TOF MS. The pure bacteria were tested by MALDI-TOF MS, and the obtained spectra were compared with those captured by Fe₃O₄ from LB media. As shown in Figure 3, the spectra of captured bacteria (*S. aureus* and *K. pneumoniae*) from LB media show similar profiles to pure bacteria. For evaluation of reproducibility, the sample of *S. aureus* in LB broth was carried out in triplicate, and each sample was deposited at three spots; the obtained spectra all show matched profiles (Supplementary Figure S5). These results indicated the feasibility of the proposed method for rapid identification of bacteria in clinical bacterial liquid cultures.

### Identification of Bacteria in a Patient With Open Fracture

Rapid and accurate identification of progressive bacteria colonizing orthopedic trauma, especially open fracture, is important for clinical diagnosis and treatment to avoid posttraumatic or postoperative infections. In the case presented here, the patient’s leg suffered an open fracture on the coastal sea of China. Fe₃O₄ possesses a universal enrichment capacity for different pathogens, and MALDI-TOF MS can identify a wide range of pathogens, including bacteria and fungi, with high accuracy at both the genus and species level (97–99% and 85–97%, respectively) (Patel, 2013). Considering the special of this case, we attempt to use MALDI-TOF MS in coupling with Fe₃O₄ enrichment for the identification of probable pathogens in this case. For analysis of clinical bacterial samples, a short-term subculture step is always needed since the amount of ~10⁶ CFU is requisite for MALDI-TOF MS identification. Herein, the wound swab and fluid were short-term cultured in liquid LB media, and the liquid samples were analyzed by the proposed method. As a control, a sterile swab was
cultured in liquid LB media in parallel. Four sample spots were tested in parallel, and the representative mass spectrum is shown in Figure 4. The mass spectra of the bacteria in the wound swab matched *Vibrio alginolyticus* (*V. alginolyticus*), a common pathogenic bacteria of numerous aquatic animals that is widely present in the sea, with an average score of 2.15 (Table 1). The fluid sample was also identified as *V. alginolyticus*, with an average score of 2.31 (Table 1). Thus, these scores indicated that the identification results were reliable at the species level. The LB media of the control group keep the clear liquid phase, and the identification results by the proposed method were unreliable (score <1.7), indicating that the control group is negative for bacteria.

**Verification of the Results**

To verify the results, short-term–cultured liquid samples continue to grow on a solid medium, and the isolates were analyzed by MALDI-TOF MS. The results were consistent with those obtained by magnetic enrichment coupled with MALDI-TOF MS (Table 1 and Supplementary Figure S6).
Furthermore, Gram staining showed that the bacteria were Gram-negative rods (Supplementary Figure S7), and the pathogen was identified as *V. alginolyticus* by the VITEK2-Compact automatic bacterial identification system. *V. alginolyticus*, a type of Gram-negative opportunistic bacteria, infects both humans and aquatic animals (Xie et al., 2020). This infection is one of the main causes of aquaculture disease resulting in economic losses in mariculture in South China (Xie et al., 2005; Yu et al., 2018; Yu et al., 2019). Therefore, it was not surprising that *V. alginolyticus* was identified in this case. The whole process of the routine method required >24 h. The identification results from MALDI-TOF MS coupled with Fc-MBL@Fe₃O₄ enrichment were in agreement with the conventional method and required only ~9 h.

**CONCLUSION**

In conclusion, direct pathogen identification from liquid-cultured clinical samples can be achieved by MALDI-TOF MS identification and appropriate pre-purification. Fc-MBL@Fe₃O₄ could recognize and capture broad-spectrum microbes, and therefore, it is adaptable to combine with MALDI-TOF MS. In this study, we identified *V. alginolyticus* in a patient with an open fracture using MALDI-TOF MS profiling coupled with Fc-MBL@Fe₃O₄ enrichment. With extension of the MALDI microbial database, particularly for bacterial mixtures, magnetic enrichment coupled with MALDI-TOF MS has great potential for more clinical samples.
