Journal of Evolution of Medical and Dental Sciences 2015; Vol.4, Issue 06, January 19; Page: 925-932, DOI: 10.14260/jemds/2015/132

ABSTRACT: BACKGROUND: Metabolic syndrome is a specific clustering of cardiovascular risk factors, which increases the mortality and morbidity. Hence, we aimed to know the incidence of METS in coronary artery disease proven by coronary angiogram and assess its various components and its impact on the in hospital prognosis of 1 week. METHODS: A total of 100 CAD cases admitted to CCU of Government General Hospital, Guntur were studied over a period of 1 year. Cases were categorized according to the NCEP ATP III METS criteria (presence of ≥3 of the following: hyperglycemia; triglycerides ≥150mg/dl; HDL-C ≤40 mg/dl for males, ≤50mg/dl for females; blood pressure ≥130/85mg/dl; waist Circumference >102 cm in men or >88 cm in women). RESULTS: Among the 100 cases, 44 (44%) fulfilled the criteria for METS and were more likely to be women. Low HDL-C (95%) was the most prevalent component followed by high TGs (95%), hyperglycemia (82%), HT (86%) and high WC (39%). In hospital complications (1week) were higher in METS patients compared to those without and associated with four fold (odds ratio 3.8, p value <0.001) increased risk of complications including heart failure (52%). CONCLUSION: The prevalence of METS was high in coronary artery disease, associated with worse in hospital prognosis of 1week and with four fold higher risk of development of complications including heart failure.

KEYWORDS: Metabolic syndrome, Myocardial infarction.

INTRODUCTION: Coronary Heart Disease (CHD) has reached enormous proportions striking more and more at younger subjects. It will result in coming years the greatest epidemic mankind has faced; unless we are able to reverse the trend by concentrating on research into its cause and prevention.1 Coronary Heart disease and its major manifestations were a medical rarity prior to first world war.2

The prevalence of coronary heart disease is on the raise in our country, more so in South India cutting across all class and age distinctions, imposing severe burden on the health care system. Hence the present study aims to address the reasons for high prevalence of CAD and the risk factors involved, namely the Metabolic Syndrome.3 Metabolic syndrome refers to constellation of inter-related cardiac risk factors that appear to directly promote development of atherosclerotic cardiovascular disease.4 A recent review of insulin resistance syndrome revealed a rapid escalation of this syndrome among Indians and the prevalence of predominant component of METS varies from region to region.5

Studies have revealed the pathophysiology of this syndrome, with close to a six fold increase in cardiovascular mortality in those possessing this disorders.6 The increased risk of morbidity and mortality associated with the METS makes it essential that there be a clear understanding of the dimensions of this syndrome for the allocation of health care and research resources and for other purposes.7 Data regarding the prevalence of metabolic syndrome in coronary artery disease from this part of the country is scanty and conclusions are drawn based on the studies done in northern India.
Indian population is non-homogeneous and data specific to this region is a dire necessity which this study aims to address.

Only very few studies have reported on the prevalence of IRS as a whole in the native Indian population based on epidemiological studies. This is particularly relevant as India has the maximum number of diabetes patients in any given country in the world.8

This study was conducted in a large teaching hospital with a medical college fully equipped with a cardiology department with cath lab facility and located in the heart of Andhra Pradesh, thereby attracting representative population from all areas and especially the lower strata of society. Results of this study are therefore relevant to the general public in this part of the country. By examining the prevalence of metabolic syndrome in established CAD, this study aims to create awareness regarding the syndrome so that by early intervention, this menace could be tackled effectively.

OBJECTIVES:
1. To assess the prevalence of metabolic syndrome in angiogram proven coronary artery disease.
2. To assess the extent of coronary artery disease in patients with metabolic syndrome.

MATERIALS AND METHODS: This study is based on analysis of 100 patients admitted to the CCU of Government General hospital attached to the Medical College, Guntur during a period from March 2013 to March 2014.

CRITERIA: The proforma was used for the selection of patients with definitive evidence of myocardial infarction.

INCLUSION CRITERIA:
- Patients with evidence of coronary artery disease proven by coronary angiogram.
- Age > 30 years independent of sex.

EXCLUSION CRITERIA:
- Patients with evidence of coronary artery disease who has not undergone coronary angiogram.
- Patients having coexisting valvular heart disease.
- Age < 30 years.

All patients of CAD including both STEMI, and NSTEMI were included.
A final diagnosis of CAD was made in the presence of serial increases in serum biochemical markers of cardiac necrosis, has associated with typical electrocardiographic changes and by coronary angiography and/or typical symptoms as defined by the joint committee of the European society of cardiology and the American college of cardiology.

Patients with ST segment elevation or new or suspected new left bundle branch block on admission electrocardiogram were defined as having ST segment elevation MI (STEMI). The remaining patients were categorized as having non-STEMI.
CRITERIA OF DIAGNOSIS OF METS: The NCEP-ATP III definition was used for the diagnosis of METS includes any three of the following:

- **Central obesity**: waist circumference > 102 cm (male) or > 88 cm (female).
- **Hypertriglyceridemia**: triglycerides ≥ 150 mg/dl
- **HDL cholesterol**: <40 mg/dl (male) or <50 mg/dl (female)
- **Hypertension**: blood pressure ≥ 130 /85 mmHg or medication.
- **Fasting plasma glucose**: ≥ 110mg/dl.

A detailed case history was taken including the symptoms, past history of diabetes mellitus, HT, smoking and alcohol consumption.

A careful physical examination was done with special reference to resting BP before discharge, WC, Height and weight. The BMI was calculated using the formula BMI = Weight in kg/Height in m^2.

WC was recorded according to the national health and nutrition survey. “The subject stand and the examiner, positioned at the right of the subject, palpates the upper bone to locate the iliac crest. Just above the uppermost lateral border of right iliac crest, a horizontal mark is drawn, and then crossed with vertical mark on the midaxillary line.

RESULTS:

| Total No. of coronary artery disease | No. of cases admitted |
|--------------------------------------|-----------------------|
| Total No. of coronary artery disease | 100                   |
| METS with CAD                        | 44 (44%)              |

**TABLE 1: TOTAL ADMITTED CASES IN CCU OF ACUTE MI**

A total of 100 cases of acute CAD admitted during the 1 year study period, out of which 44 cases had METS which showed an overall percentage of 44% in the present study. These findings suggest the METS, as defined by the NCEP ATP III criteria, is very common among patients with CAD, because almost 1 in 2 patients had METS and that is associated with advanced coronary artery vascular damage.

This high incidence may be related to the vascular damage in METS by oxidative stress, endothelial dysfunction and pro-inflammatory state.

| Age (years) | With METS (n = 44) | Without METS (n = 56) | Total |
|-------------|-------------------|-----------------------|-------|
|             | No.   | %    | No.   | %    | No. | %    |
| 31-40       | 8     | 18   | 9     | 16   | 17  | 17   |
| 41-50       | 14    | 32   | 20    | 36   | 34  | 34   |
| 51-60       | 13    | 30   | 14    | 25   | 27  | 27   |
| 61-70       | 6     | 14   | 12    | 21   | 18  | 18   |
| 71-80       | 3     | 7    | 1     | 2    | 4   | 4    |
| Total       | 44    | 56   | 100   |      |     |      |

**TABLE 2: AGE GROUPING**
The age incidence was more between the age group 41-50 years followed by 51-60 years in both the groups. There was no statistical difference in age between the 2 groups. (p value 0.48) NS 

There is early incidence of METS in CAD patients in the present study compared to the other studies. About 25% CAD in India occurs under the age of 40 and 50% under 50\textsuperscript{10}. In general MI develops 5-10 years earlier in Asian Indian than in other population\textsuperscript{11-12}.

| Sex       | CAD with METS | CAD without METS | Total |
|-----------|---------------|-----------------|-------|
|           | N = 44        | %              | N = 56 | %         | N = 100 | %         |
| Males     | 33            | 75             | 44     | 79        | 77      | 77        |
| Females   | 11            | 25             | 12     | 21        | 33      | 33        |

Table 3: SEX DISTRIBUTION

Chi-square test. \(X^2=1.33, p\ value = 0.25\) NS.

It was observed that 77 case among the 100 studied cases were male. The males predominated in both the groups. The METS was more in females with MI but it was not statistically significant. (p value 0.25)NS. Comparison between the two groups indicates that patients with METS were more likely to be a female, which was consistent with the other studies. In the present study, confounding factors like pre or post-menopausal status and presence or absence of anemia have not yielded statistically significant results. Higher waist circumference and BMI appeared to play a more significant role in female subjects than in males.

| Symptoms                | With METS (n = 44) | Without METS (n = 56) | Total |
|-------------------------|-------------------|-----------------------|-------|
|                         | No.               | %                     | No.   | %         | No.   | %         |
| Chest pain              | 42                | 95                    | 56    | 100       | 98    | 98        |
| Breathlessness          | 14                | 32                    | 11    | 20        | 25    | 25        |
| Cough/sputum            | 8                 | 18                    | 10    | 18        | 18    | 18        |
| Palpitation             | 7                 | 16                    | 8     | 14        | 15    | 15        |
| Syncope                 | 2                 | 4.5                   | 1     | 2         | 3     | 3         |
| Sweating                | 25                | 56                    | 20    | 36        | 45    | 45        |
| Vomiting                | 2                 | 4.5                   | 5     | 9         | 7     | 7         |

TABLE 4: SYMPTOMATOLOGY AT PRESENTATION

The most common mode of presentation in both groups was chest pain followed by sweating. Breathlessness (32% vs. 20%) & sweating (56% vs. 36%) were more common in METS compared to those without METS.

| Risk factors            | With METS (n = 44) | Without MET (n = 56) | Total |
|-------------------------|-------------------|----------------------|-------|
|                         | No.               | %                    | No.   | %        | No.   | %        | P* value, sig. |
| Diabetes Mellitus       | 25                | 57                   | 16    | 29       | 41    | 41       | 0.004 S       |
| Hypertension            | 24                | 56                   | 16    | 29       | 35    | 35       | 0.01 S        |
| Family History          | 12                | 27                   | 12    | 21       | 24    | 24       | 0.49 NS       |
Chi-square test. S=Significant, NS=Not Significant.

The past history of DM and HT were more common in the METS group compared to those without METS which were statistically significant. There was no significant difference in the current history of smoking, alcohol consumption and family history of CAD in both the groups.

![Table 5: Risk Factors](https://example.com/table5)

| Components of METS | With METS (n = 44) | Without MET (n = 56) | Total | P* value, sig. |
|--------------------|--------------------|----------------------|-------|---------------|
|                    | No. | %    | No. | %    | No. | %    |       |               |
| FBS = 110mg/dl     | 36  | 82   | 21  | 38   | 57  | 57   |       | P < 0.001 HS  |
| HTN or BP = 130/85 mm Hg | 37 | 84   | 12  | 21   | 49  | 49   |       | P < 0.001 HS  |
| TGS = 150 mg/dl    | 42  | 95   | 18  | 32   | 60  | 60   |       | P < 0.001 HS  |
| HDL < 40 mg/dl(males) <50 mg/dl(females) | 42 | 95   | 32  | 57   | 74  | 74   |       | P < 0.001 HS  |
| Waist circumference >102 cm(males) > 88 cm(females) | 17 | 39   | 8   | 14   | 25  | 25   |       | 0.01 S       |

![Table 6: Components of METS](https://example.com/table6)

| Components of METS | MI with METS | MI without METS | P value |
|--------------------|--------------|-----------------|---------|
| FBS (mg/dl)        | 174.2 ± 66   | 133.3 ± 54.2    | 0.001 HS|
| TC (mg/dl)         | 186.5 ± 46.7 | 191.2 ± 49.8    | 0.63 NS |
| TGS (mg/dl)        | 246.1 ± 109.8| 157.9 ± 46.3    | < 0.001 HS |
| HDL-C (mg/dl)      | 35.8 ± 5.6   | 39.1 ± 3.9      | < 0.001 HS |
| LDL-C (mg/dl)      | 137.3 ± 40.4 | 129.1 ± 41.2    | 0.31 NS |
| SBP mm of Hg       | 139.6 ± 29.4 | 128.8 ± 23.1    | 0.04 S  |
| DBP mm of Hg       | 88.2 ± 19.6  | 81.6 ± 10.1     | 0.03 S  |

Unpaired t test. HS= Highly significant, NS: Not significant, S=Significant.

It was observed that, the all the components were more common in the METS group than patients without METS and were highly significant. Low HDL-C was the major component in both the groups. High TGS is the next major component in METS group followed by the DM or FBS ≥110mg/dl,
HT or BP ≥ 130/85 and high WC. HT or BP ≥ 130/85 was the next major component in patients without METS followed by high TGS, DM or FBS ≥110mg/dl and high WC.

| Other factors               | CAD with METS | CAD without METS | Total | P value |
|-----------------------------|---------------|------------------|-------|---------|
|                             | N = 44        | N = 56           | N = 100 |
| Obesity (BMI ≥ 30kg/m²)     | 17            | 3                | 20    | 0.01 S  |
| Serum cholesterol (≥240mg/dl)| 9             | 6                | 15    | 0.63 NS |
| LDL-C > 160mg/dl            | 12            | 9                | 21    | 0.31 NS |

**TABLE 8: OTHER FACTORS**

S= Significant, NS: Not significant.

The obesity with BMI> 30Kg/m² was present in 38.6 (Mean 27.2±3.3) of patients with METS compared to 5.3% (25.7±2.4) of those without METS, which was statically significant (p Value).

| Angiogram | With METS (n = 44) | Without METS (n = 56) | Total | P* value, sig. |
|-----------|--------------------|------------------------|-------|----------------|
|           | No.   | %     | No.   | %     | No.   | %     |       |
| LAD       | 28    | 64    | 40    | 71    | 68    | 68    | 0.4 NS |
| RCA       | 8     | 18    | 14    | 25    | 22    | 22    | 0.4 NS |
| LCX       | 8     | 18    | 10    | 18    | 18    | 18    | 0.9 NS |

**TABLE 9: ANGIOGRAM**

It was observed that LAD was the most common vessel involved of the 100 studied cases 70 case 71 case were LAD and there was no much significance related to METS.

| Prognosis in 1 week of hospital stay | CAD with METS | CAD without METS | Total | P value |
|-------------------------------------|---------------|------------------|-------|---------|
|                                     | N = 44        | N = 56           | N = 100 |        |
| Heart failure                       | 23            | 10               | 33    | <0.001 HS |
| Arrhythmias VT/VF                   | 4             | 4                | 8     | 0.98 NS |
| Recurrent MI                        | 3             | 2                | 4     | 0.74 NS |

**TABLE 10: IN HOSPITAL PROGNOSIS OF CAD IN 1 WEEK**

HS= Highly Significant, NS: Not significant.

All the complication was more common in the METS group compared to those without METS group. Heart failure was present in 52% of METS patents compared to the 18% in those without METS which was statistically highly significant (P value <0.001). There was no significant difference in the development of other complications like arrhythmias (ventricular tachycardia/fibrillation), recurrent MI.
CONCLUSION: This is one of the prospective study carried out to describe the prevalence of metabolic syndrome in coronary artery disease and to assess its impact on hospital outcome.

The metabolic syndrome is a highly prevalent condition among the patients with coronary artery disease and has detrimental impact on short term outcome.

Metabolic syndrome is a clustering of risk factors of metabolic origin that are together associated with higher risk of cardiovascular disease and the need to develop strategies for controlling this syndrome and its component conditions.

In the industrialized countries there is a continuing decline of CAD during the last three decades. Between 1965-1990, CAD mortality had decreased by 60% in Japan and Finland and by 50% in USA, Canada, France, and Australia. This has been possible by focusing on public education programmes for modifying the known risk factors and by targeting high risk individuals. This achievement of the industrialized nations must become an inspiration for the physicians and the policy makers in India.

Considering that there is a strong genetic predisposition for onset of CAD in India, focus should be on cascade testing of families to identify mutations in LDL receptor gene, ApoB and ApoE gene responsible for premature onset of CAD. Innovative combination of genetic testing and cholesterol testing at an affordable price to the at-risk families with strong history of CAD is the need of the hour.

Early investigations diagnosis, treatment including lifestyle modification and prevention of the metabolic syndrome will reduce the development of cardiovascular diseases like myocardial infarction including its complications and it present a major challenge for health care professionals facing an epidemic of overweight and sedentary lifestyle.

To conclude, cardiovascular disease patients with METS must be identified and managed aggressively to reduce both morbidity and mortality since it is a preventable condition.
