COMPUTATION OF GALOIS GROUPS ASSOCIATED TO THE 2-CLASS TOWERS OF SOME QUADRATIC FIELDS

M. R. BUSH

Abstract. The \( p \)-group generation algorithm from computational group theory is used to obtain information about large quotients of the pro-2 group \( G = \text{Gal}(k^{nr,2}/k) \) for \( k = \mathbb{Q}(\sqrt{d}) \) with \( d = -445, -1015, -1595, -2379 \). In each case we are able to narrow the identity of \( G \) down to one of a finite number of explicitly given finite groups. From this follow several results regarding the corresponding 2-class tower.

1. Introduction

In recent years there has been much interest in trying to determine the behaviour of the \( p \)-class tower of a quadratic field especially in the case where \( p = 2 \). See for instance [1], [2], [4], [7] and [11]. Note that by \((p-)\text{class tower of } k\) we mean the chain of fields

\[
k = k_0 \subseteq k_1 \subseteq \ldots \subseteq k_n \subseteq \ldots
\]

where \( k_{n+1} \) is the Hilbert \((p-)\text{class field of } k_n\) for each nonnegative integer \( n \). We say that the tower is finite if \( k_n = k_{n+1} \) for some \( n \), and infinite otherwise. If it is finite then the minimal such \( n \) is called the length of the tower. In this paper we show that the 2-class towers of four imaginary quadratic fields \( k \) are finite using a computational method first introduced by Boston and Leedham-Green [4]. In fact we are able to give a short list of candidates for the Galois group \( \text{Gal}(k^{nr,2}/k) \) in each case. Here \( k^{nr,2} \) denotes the maximal unramified 2-extension of \( k \) which is obtained by taking the union of the fields occurring in the 2-class tower of \( k \).

The first field we consider is \( k = \mathbb{Q}(\sqrt{-2379}) \). It was noted by Stark [10] that this field has root discriminant \( \sqrt{|d_k|} \approx 48.8 \) which is just above the best known lower bound \((\approx 44.7 \text{ under GRH})\) for \( R = \lim \inf_{n \to \infty} R_n \) where \( R_n \) is the minimal root discriminant over all imaginary number fields of degree \( n \) (see [8]). If the class tower above \( k \) were infinite we would thus obtain a fairly tight upper bound on possible sharpenings of this lower bound (since root discriminants remain constant in class towers). Currently the best known upper bound on this lower bound is around 83.9 (see [8]) so this would be a significant improvement. We do not resolve whether or not the class tower of \( k \) is infinite here but our methods do show that the 2-class tower is finite of length 2.

The three other fields we consider are \( k = \mathbb{Q}(\sqrt{-445}), \mathbb{Q}(\sqrt{-1015}) \) and \( \mathbb{Q}(\sqrt{-1595}) \). It is observed in [1] that under GRH these fields are the first examples of imaginary fields with finite \((2-)\text{class towers} \) and \( \text{rank Cl}_2(k_1) \geq 3 \). Here we determine that

1991 Mathematics Subject Classification. Primary : 11Y40; Secondary : 11R37, 20D15.

Key words and phrases. class tower, class field, quadratic field, explicit Galois group.

The author would like to thank Nigel Boston for suggesting this problem and for many helpful discussions.
each field has finite 2-class tower unconditionally. We are also able to obtain the exact length of the tower and the 2-class groups which occur in it in each case.

2. The Method

The method is based on the $p$-group generation algorithm introduced by O’Brien \cite{5}. We now recall some definitions. Let $G$ be a pro-$p$ group. We recursively define a series of closed subgroups of $G$

$$G = P_0(G) \supseteq P_1(G) \supseteq P_2(G) \supseteq \ldots$$

by setting $P_n(G) = P_{n-1}(G)^p[G, P_{n-1}(G)]$ for each $n \geq 1$. Here the group on the right-hand side is the closed subgroup generated by all $p$th powers of elements in $P_{n-1}(G)$, and commutators of elements from $G$ and $P_{n-1}(G)$. If $G$ is a finite pro-$p$ group then the series above is finite and the smallest $c$ such that $P_c(G) = \{1\}$ will be called the $p$-class of $G$. A $p$-group $H$ is called a descendant of $G$ if $H/P_c(H) \cong G$ where $c$ is the $p$-class of $G$. It is an immediate descendant if it has $p$-class $c + 1$.

The $p$-group generation algorithm finds representatives (up to isomorphism) of all the immediate descendants of a given finite $p$-group $G$.

Now, fix an ordered pair $(G, \{G_i\}_{i=1}^n)$ where $G = \text{Gal}(k^{nr^2}/k)$ is a pro-2 group and $G_i$ is a closed subgroup of $G$ for $i = 1, \ldots, n$. We will be interested in the pairs $G_m = (G/P_m(G), \{G_i\}_{i=1}^n)$ where $m \geq 0$ and $G_i$ denotes the image of the subgroup $G_i$ under the natural map to the quotient $G/P_m(G)$. We note that $G/P_m(G)$ is always finite.

**Definition 1.** A pair $(H, \{H_i\}_{i=1}^n)$ will be called a representative of the pair $G_m$ if there exists an isomorphism $\psi : H \rightarrow G/P_m(G)$ such that $\psi(H_i) = G_i$ for each $i = 1, \ldots, n$.

We now have a lemma which follows easily from the definitions.

**Lemma 1.** Suppose that $(P, \{P_i\}_{i=1}^n)$ is a representative of $G_m$ and $(Q, \{Q_i\}_{i=1}^n)$ is a representative of $G_{m+1}$, then

1. $Q$ is an immediate descendant of $P$.
2. There exists a surjective map $f : Q \rightarrow P$ such that $f(Q_i) = P_i$ for $i = 1, \ldots, n$.

Given a representative of $G_m$ Lemma 1 allows us to compute a finite list of pairs containing a representative of $G_{m+1}$. This is because a finite group $P$ has only finitely many immediate descendants $Q$ up to isomorphism and for each descendant $Q$ there are only finitely many surjective maps $f : Q \rightarrow P$. Thus, starting with a list of pairs known to contain a representative of $G_t$ for some $t$ we can (by applying Lemma 1 repeatedly) compute a list of pairs which must contain a representative of $G_m$ for any $m > t$.

As it stands the above is not particularly useful since the number of pairs grows very quickly with $m$. To try to eliminate some of these we now suppose that we know the direct product decomposition of the abelian group $G_i/G'_i$ into cyclic groups for $i = 1, \ldots, n$. From now on this information about the decomposition will be referred to as the abelian quotient invariants of $G_i$. It will usually be given by listing the orders of the cyclic subgroups involved, so for instance if $G_i/G'_i \cong C_2 \times C_4 \times C_4$ (where $C_2$ and $C_4$ are cyclic groups of orders 2 and 4 respectively) then we would say that $G_i$ has abelian quotient invariants $[2, 4, 4]$. We note that in practice it is possible to get hold of such information for low index subgroups of $G$ by computing
the 2-Sylow subgroups of the ideal class groups of small subextensions of $k^{nr,2}/k$ and then applying Class Field Theory. If we also assume that $G_i \supseteq P_i(G)$ for each $i$ then for $m \geq t$ the abelian quotient invariants of the image of $G_i$ in $G/P_m(G)$ must be a quotient of those of $G_i$. In the examples considered below the application of these additional restrictions drastically reduces the number of candidates for representatives of $G_{(m)}$ for each $m$ allowing us to obtain useful information about the extension $k^{nr,2}/k$.

In summary, given a list of pairs $L_m$ containing a representative of $G_{(m)}$ we compute a list $L_{m+1}$ containing a representative of $G_{(m+1)}$ as follows

1. For each pair $(P, \{P_i\}_{i=1}^n)$ in $L_m$ we compute a list of all the immediate descendants of $P$ (up to isomorphism) using the $p$-group generation algorithm.
2. For each immediate descendant $Q$ we construct all possible surjective maps $f : Q \rightarrow P$.
3. For each $Q$ and $f : Q \rightarrow P$ we check to see whether the abelian quotient invariants of $f^{-1}(P_i)$ are a quotient of those of $G_i$ for every $i = 1, \ldots, n$. If this is the case then the pair $(Q, \{f^{-1}(P_i)\}_{i=1}^n)$ is appended to the list $L_{m+1}$.

In practice we can usually compute a suitable starting list $L_1$ or $L_2$. In the examples considered in the next section the sequence of lists $L_m$ that are then generated terminate, i.e. $L_m$ is empty for sufficiently large $m$. This implies that $G = \text{Gal}(k^{nr,2}/k)$ actually occurs as a group in one of the pairs on these lists and so must be finite. We now note that if $(H, \{H_i\}_{i=1}^n)$ is a representative of $(G, \{G_i\}_{i=1}^n)$ then the abelian quotient invariants of $H_i$ must match those of $G_i$ exactly. This observation motivates the following definition.

**Definition 2.** A finite group $H$ will be called a candidate for $G$ if there exists a pair $(H, \{H_i\}_{i=1}^n)$ such that the abelian quotient invariants of $H_i$ are equal to those of $G_i$ for all $i = 1, \ldots, n$.

As we generate pairs we keep track of all the candidates for $G$ that we find since in the event the sequence of lists terminate we know that $G$ must be isomorphic to one of them.

### 3. Some Examples

Two packages were used to carry out the actual computations in this section. KASH (see [3]) was used to construct 2-class fields above $k$ up to degree 16, as well as for ideal class group computations. MAGMA (see [3]) was used to calculate ideal class groups, as well as determining the subfield lattices and Galois groups of certain degree 16 subextensions of $Q$. We also made use of MAGMA’s implementation of the $p$-group generation algorithm. Throughout this section $G = \text{Gal}(k^{nr,2}/k)$.

**3.1. The field $k = Q(\sqrt{-2379})$.** Using KASH we have $G/G' \cong [4, 4]$. It follows from this that $G/P_1(G) \cong [2, 2]$.

Calculation of some 2-class fields shows that $Q(\sqrt{-3}, \sqrt{13}, \sqrt{61})$ is a degree 4 subextension of $k^{nr,2}/k$ with Galois group over $k$ equal to $[2, 2]$. This implies that the subgroup $P_1(G)$ of $G$ corresponds to the subfield $Q(\sqrt{-3}, \sqrt{13}, \sqrt{61})$. The following table shows the intermediate fields together with the abelian invariants of the 2-Sylow subgroup of the corresponding ideal class group.
We can thus construct a representative of \( G^{(1)} = (G/P, \{G_i\}_{i=1}^5) \) where the groups \( G_i \) are the subgroups of \( G \) corresponding to the intermediate fields of the extension \( \mathbb{Q}(\sqrt{-3}, \sqrt{13}, \sqrt{61})/k \). Let \( L_1 \) be the list containing just this pair. We now apply the method from Section 2 using the abelian quotient invariants given in the table to generate a sequence of lists \( L_m \) for \( m > 1 \). The collection of groups that occur in the pairs in these lists can be represented by a tree as shown in Figure 1.

Figure 1. A tree of groups

In this picture we have only displayed vertices which represent groups having at least one immediate descendant and which occur in one of the lists \( L_m \). Groups which do not have any descendants but which occur in one of the lists are not shown. This is done primarily for convenience since including such (terminal) groups would clutter up the picture and we are really only interested in determining whether or not this and other such trees are finite. Note that in this tree a vertex \( Q \) is a child of another vertex \( P \) if the group corresponding to \( Q \) is an immediate descendant of the group corresponding to \( P \). Thus the vertex numbered 0 corresponds to the group \([2, 2]\) of 2-class 1 (from the pair in \( L_1 \)). The groups numbered 1 to 6 have 2-class 2 and come from the pairs in \( L_2 \) and so on. Note that the groups in each level of the tree are pairwise nonisomorphic but each one may occur in more than one pair on the corresponding list.

While generating the lists a total of 81 candidates for \( G \) were found (all of them descendants of the group corresponding to vertex 6). Most of these are not displayed.
in Figure 1 since they do not have any descendents. At this stage we cannot conclude that $G$ must be one of these groups since after several computations part of the tree (below vertex 4) is still growing. We have however gained some useful information about the quotient $G/P_2(G)$. In particular since no candidates for $G$ were found in the finite subtrees lying below vertices 1,2,3 and 5 we can conclude that $G/P_2(G)$ must be isomorphic to the group corresponding to either vertex 4 or vertex 6. Let us denote these two groups by $H_4$ and $H_6$ respectively. $H_4$ is generated by \( \{ x_i \}_{i=1}^4 \) subject to the power commutator presentation

\[
H_4 : x_1^2 = x_4 \quad [x_2, x_1] = x_3
\]

$H_6$ is generated by \( \{ x_i \}_{i=1}^5 \) subject to the power commutator presentation

\[
H_6 : x_1^2 = x_4 \quad x_2^2 = x_5 \quad [x_2, x_1] = x_3
\]

**Remark 1.** Note that in any power commutator presentation if a power $x_r^t$ or commutator $[x_r, x_s]$ does not occur on the left hand side of the given relations then it is assumed to be trivial.

Using KASH we can find a degree 16 Galois extension $L$ over $\mathbb{Q}$ unramified over $k$. One such field is defined by the polynomial

\[
x^{16} - 2158x^{14} - 1166x^{13} + 1886402x^{12} + 1125558x^{11} - 73896514x^{10} + 24633036x^9 + 88589769625x^8 - 114401828130x^7 + 12435312336118x^6 + 15732271973132x^5 + 506694031967064x^4 - 98005626098698x^3 + 10557300816504844x^2 - 7195589177918350x + 41648817878658175
\]

and its Galois group is the direct product of the dihedral group of order 8 and the cyclic group of order 2. By considering the lattice of subfields of this extension over $k$ it can be shown that $\text{Gal}(L/k) \cong [2,4]$. The lattice of subfields and the 2-Sylow subgroups of the corresponding ideal class groups are shown in Figure 2.

![Figure 2. A lattice of subfields and 2-class groups](image)

Now $[2,4]$ is a group of 2-class 2 which means that the subgroup $P_2(G)$ of $G$ corresponds to some intermediate field of the extension $k^{nr,2}/L$. So we consider the pair $G_{(2)} = (G/P_2(G), \{G_i\}_{i=1}^7)$ where $G_i$ are the subgroups of $G$ corresponding to the intermediate fields (of degree at most 4) in the lattice above. A list $L_2$ containing a representative of $G_{i(2)}$ can be constructed by taking each group $H_r$ ($r = 4$ or $r = 6$) and adjoining all pairs of the form $(H_r, \{f^{-1}(R_i)\}_{i=1}^7)$ where $f$
runs through all the surjective homomorphisms from $H_r$ onto $[2, 4]$ and \{R_i\}_{i=1}^7 are the subgroups of $[2, 4]$ of index at most 4. When the method from Section 2 is applied to $L_2$ the sequence of lists generated terminates. The extra information about the abelian quotient invariants of the two additional subgroups of index 4 is restrictive enough to show $G$ must be finite. The number of candidates for $G$ found (with the additional restrictions) also decreases from 81 to 24. An investigation of these 24 groups shows that they fall naturally into two classes based on the abelian quotient invariants of their subgroups of index 4. In one of the classes (consisting of 8 groups) each group has several subgroups of index 4 with abelian quotient invariants $[4, 32]$. None of the subgroups of index 4 of the groups in the other class have these invariants. KASH can be used to show that the extension of $\mathbb{Q}$ defined by the polynomial
\[ x^8 + 9494x^6 + 33992937x^4 + 54094064336x^2 + 32175758727424 \]
is an unramified extension of $k$ with ideal class group $[4, 32]$. We conclude that $G$ must be isomorphic to one of 8 possible groups. Each one of these can be obtained by selecting $r, s, t \in \{0, 1\}$ and then considering the group generated by $\{x_i\}_{i=1}^{11}$ subject to the power commutator presentation
\[
[x_2, x_1] = x_3 \quad [x_4, x_3] = x_{10} \quad [x_6, x_1] = x_9
\[
[x_3, x_1] = x_6 \quad [x_5, x_1] = x_6x_7x_8x_9x_{10} \quad [x_8, x_1] = x_{10}
\]
\[
[x_3, x_2] = x_7 \quad [x_5, x_3] = x_{10}x_{11} \quad [x_8, x_2] = x_{10}x_{11}
\]
\[
[x_4, x_2] = x_8 \quad [x_5, x_4] = x_{10}x_{11} \quad [x_9, x_1] = x_{11}
\]
\[
x_1^2 = x_4 \quad x_5^2 = x_6x_9x_{10}x_{11}
\]
\[
x_2^2 = x_5 \quad x_6^2 = x_9x_{10}x_{11}
\]
\[
x_3^2 = x_6x_8x_9x_{10} \quad x_7^2 = x_{10}x_{11}
\]
\[
x_4^2 = x_7x_{11} \quad x_9^2 = x_{11}
\]
Remark 1 about power commutator presentations applies here also.

The 8 groups defined by these presentations are very similar. They all have order 2$^{11}$ and 2-class 5. They also possess derived series of the same length and with the same abelian factors. This allows us to deduce

**Proposition 1.** The 2-class tower of the imaginary quadratic field $k = \mathbb{Q}(\sqrt{-237})$ is finite of length 2, i.e. $k = k_0 \subset k_1 \subset k_2 = k^{nr,2}$. We have $\text{Gal}(k_1/k_0) \cong [4, 4]$ and $\text{Gal}(k_2/k_1) \cong [2, 4, 16]$.

3.2. The field $k = \mathbb{Q}(\sqrt{-445})$. In this case $G/G' \cong [2, 4]$ so we still have $G/P_1(G) \cong [2, 2]$. The field $\mathbb{Q}(\sqrt{-1}, \sqrt{5}, \sqrt{89})$ is a degree 4 subextension of $k^{nr,2}/k$. We can calculate the 2-Sylow subgroup of the ideal class group of each intermediate field, and construct a representative of the pair $G_{(i)} = (G/P_1(G), \{G_i\}_{i=1}^5)$ where the groups $G_i$ are the subgroups of $G$ corresponding to the intermediate fields. Applying the method from Section 2 we are able to narrow down $G/P_2(G)$ to one of 3 groups. Two of these can be identified as $[2, 4]$ and $D_4$ (the dihedral group of order 8). These can be eliminated as possibilities since it is easy to find examples of degree 8 subextensions of $k^{nr,2}/k$ with either of these groups as the Galois group. This implies that both groups must arise as quotients of $G/P_2(G)$. It follows that $G/P_2(G)$ must be isomorphic to the remaining group of order 16 which we will
denote $H_3$. The group $H_3$ is actually isomorphic to the group $H_4$ in the previous example.
As before we now consider an unramified degree 8 extension $L$ over $k$ defined over $\mathbb{Q}$ by the polynomial
\[
x^{16} + 12x^{14} + 4554x^{12} + 17928x^{10} + 2231251x^8 + 13625880x^6 - 10866150x^4 - 143437500x^2 + 244140625
\]
We have $\text{Gal}(L/k) \cong [2,4]$. The lattice of subfields of $L/k$ together with the 2-Sylow subgroups of the corresponding ideal class groups can be seen in Figure 3.

We construct $L_2$ by adjoining all pairs of the form $(H_3, \{f^{-1}(R_i)\})_{i=1}^7$ where $f$ runs over all the surjective maps from $H_3$ to $[2,4]$ and $\{f^{-1}(R_i)\}_{i=1}^7$ are the subgroups of $[2,4]$ of index at most 4. When we apply the method starting with $L_2$ the sequence of lists generated terminates and a total of 12 candidates for $G$ are found. To try and determine which one is isomorphic to $G$ we look again at the abelian quotient invariants of their index 4 subgroups. We find that only 2 of the 12 groups have an index 4 subgroup with invariants $[2,16]$. KASH can be used to show that the extension of $\mathbb{Q}$ defined by the polynomial
\[
x^8 + 702x^4 + 130321
\]
is an unramified extension of $k$ with the 2-Sylow subgroup of its ideal class group equal to $[2,16]$. It follows that $G$ must be isomorphic to one of these two groups.

Each one of these can be obtained by selecting $r \in \{0,1\}$ and then considering the group generated by $\{x_i\}_{i=1}^8$ subject to the power commutator presentation
\[
\begin{align*}
[x_2, x_1] &= x_3 & [x_5, x_2] &= x_8 & x_1^2 &= x_4 \\
[x_3, x_1] &= x_5 & [x_5, x_3] &= x_8 & x_2^2 &= x_5x_7 \\
[x_3, x_2] &= x_6 & [x_5, x_4] &= x_8 & x_3^2 &= x_6x_7 \\
[x_4, x_2] &= x_5x_6x_7x_8 & [x_7, x_1] &= x_8 & x_6^2 &= x_8 \\
[x_4, x_3] &= x_7 & [x_7, x_2] &= x_8 & \\
[x_5, x_1] &= x_7 & x_4^2 &= x_5^2
\end{align*}
\]
Remark 2 about power commutator presentations applies here also. Once again these groups are very similar. They both have order $2^8$ and 2-class 5 and by looking at their derived series we deduce
Proposition 2. The field $k = \mathbb{Q}(\sqrt{-445})$ has finite 2-class tower of length 3, i.e.
$k = k_0 \subset k_1 \subset k_2 \subset k_3 = k^{nr,2}$. We have $\text{Gal}(k_1/k_0) \cong [2,4]$, $\text{Gal}(k_2/k_1) \cong [2,2,4]$ and $\text{Gal}(k_3/k_2) \cong [2]$

Remark 2. We note that the finiteness of the towers in the propositions above is purely a group theoretic result. Any field $k$ for which there exists a degree 8 subextension $L$ of $k^{nr,2}/k$ such that the lattice of subfields and corresponding 2-class groups are the same as those in Figures 3 and 5 must also have a finite 2-class tower.

Remark 3. In each of the previous examples a single unramified degree 8 extension of $k$ was selected. The number theoretic information provided by this extension was sufficient for us to be able to show the finiteness of $\text{Gal}(k^{nr,2}/k)$ in each case. One obvious way to extend the algorithm would be to incorporate the information from several such extensions at the same time. In some sense we were already doing this (in an ad hoc fashion) when we took the initial finite list of candidates in each of the previous examples and eliminated some of them using additional number theoretic information. More precisely we now consider pairs of the form $(H, \{\{H^{(j)}\}^i_{i=1}\}_{j=1}^t)$ where $t$ is the number of extensions under consideration. Such a pair will be called a representative of $G_{(m)}$ if there exists a family of isomorphisms $\psi_j : H \rightarrow G/P_m(G)$ such that $\psi_j(H^{(j)}_i) = \overline{G}_i$ for each $i = 1, \ldots, n$ and $j = 1, \ldots, t$. As before given a list of pairs $L_m$ containing a representative of $G_{(m)}$ we can use the p-group generation algorithm to compute a list $L_{m+1}$ containing a representative of $G_{(m+1)}$.

3.3 The fields $k = \mathbb{Q}(\sqrt{-1015})$ and $\mathbb{Q}(\sqrt{-1595})$. In both cases $G/G' \cong [2,8]$ so we have $G/P_1(G) \cong [2,2]$. The fields $\mathbb{Q}(\sqrt{-7}, \sqrt[4]{5}, \sqrt[8]{29})$ and $\mathbb{Q}(\sqrt{-11}, \sqrt[4]{5}, \sqrt[8]{29})$ are degree 4 subextensions of $k^{nr,2}/k$ in each case. We can calculate the $2$-Sylow subgroup of the ideal class group of each intermediate field, and construct a representative of the pair $G_{(1)} = (G/P_1(G), \overline{G}_1^3_{i=1})$ where the groups $G_i$ are the subgroups of $G$ corresponding to the intermediate fields. For both the given fields we get the same representative of $G_{(1)}$. Applying the method from Section 2 we are able to narrow down $G/P_2(G)$ to one of 4 groups. Two of these can be identified as $[2,4]$ and $D_4$ (the dihedral group of order 8). These can be eliminated as possibilities since it is easy to find examples of degree 8 subextensions of $k^{nr,2}/k$ with either of these groups as the Galois group (see below). This implies that both groups must arise as quotients of $G/P_2(G)$. It follows that $G/P_2(G)$ must be isomorphic to one of the remaining two groups of order 16 which we will denote $H_3$ and $H_4$. The group $H_3$ is actually isomorphic to the group $H_3$ in the previous example.

Now taking into account Remark 3 we consider several unramified degree 8 extensions $L$ over $k$ instead of only one. For $k = \mathbb{Q}(\sqrt{-1015})$ we consider the fields defined over $\mathbb{Q}$ by the polynomials

$L_1 : \quad x^{16} + 8302x^{14} + 29865815x^{12} + 60621449422x^{10} + 75762817738769x^8 + 59625975137422568x^6 + 28858765154851072400x^4 + 7861191091575524181248x^2 + 92418232972720716353536$

$L_2 : \quad x^{16} + 68x^{14} - 26x^{13} + 1922x^{12} - 2316x^{11} + 29806x^{10} - 20958x^9 + 335885x^8 + 62002x^7 + 1639268x^6 + 2747082x^5 + 6227217x^4 + 7583004x^3 + 7628823x^2 + 4664142x + 1486431$
For \( k = \mathbb{Q}(\sqrt{-1595}) \) we consider the fields defined over \( \mathbb{Q} \) by the polynomials

\[
L_1 : \quad x^{16} + 75x^{14} + 3384x^{12} + 1497421x^{10} + 14831500x^8 + 12999744x^6 + 564715200x^4 + 1475789056x^2 + 13918403354887798784x^2
\]

\[
+ 793394183478882017536
\]

\[
L_2 : \quad x^{16} + 145x^{14} + 1087x^{12} + 336690x^{10} + 2932126x^8 + 22696270x^6 + 32760881x^4 - 90377775x^2 + 43046721
\]

\[
L_3 : \quad x^{16} - 2312x^{14} + 2359542x^{12} - 1183214812x^{10} + 276742820433x^8 - 63131144780036x^6 + 66951555767033248x^4 - 13918403354887798784x^2
\]

\[
+ 793394183478882017536
\]

In each case we obtain three lattices of subfields together with the 2-Sylow subgroups of the corresponding ideal class groups. These turn out to be the same for both \( k = \mathbb{Q}(\sqrt{-1015}) \) and \( k = \mathbb{Q}(\sqrt{-1595}) \) and are displayed in Figure 4. Note that \( \text{Gal}(L_1/k) = D_4 \), \( \text{Gal}(L_2/k) = [2, 4] \) and \( \text{Gal}(L_3/k) = D_4 \). A list \( L_2 \) containing a representative of \( G_{(2)} \) (see the modified definition in Remark 3) can be constructed by taking each group \( H_r \) (\( r = 3 \) or \( r = 4 \)) and adjoining all pairs of the form \( \langle f_j^{-1}(R_i^{(j)}) \rangle \in I_j \) where \( f_j \) runs through all the surjective homomorphisms from \( H_r \) onto \( \text{Gal}(L_j/k) \) and \( \{ R_i^{(j)} \} \) are the subgroups of \( \text{Gal}(L_j/k) \) of index at most 4. Here \( I_j \) is simply an indexing set for the subgroups, its size being determined by the structure of \( \text{Gal}(L_j/k) \). When the method from Section 2 is applied to \( L_2 \) the sequence of lists generated terminates and a total of 2 candidates for \( G \) are found. Each one of these can be obtained by selecting \( r \in \{ 0, 1 \} \) and

\[
\begin{align*}
L_3 : & \quad x^{16} + 208250x^{14} + 6454080x^{13} + 84986985877x^{12} - 319881524440x^{11}
+ 1050418617556042x^{10} + 3217249977395280x^9 + 2231207353583753604x^8
- 416523219752629706680x^7 + 162122207446262754901910082x^6
- 44492763756609875614160120x^5 + 231698962045584579544307721749x^4
- 46682108628574071299245171753200x^3
+ 79672649360104768243767297422156178x^2
- 379024708745623815695570165787116760x
+ 8159585378826852513556627342521162440521
\end{align*}
\]
then considering the group generated by \( \{ x_i \}_{i=1}^{9} \) subject to the power commutator presentation

\[
\begin{align*}
[x_2, x_1] &= x_3 & [x_5, x_2] &= x_9 & x_2^2 &= x_5 x_7 \\
[x_3, x_1] &= x_5 & [x_5, x_3] &= x_9 & x_3^2 &= x_7 x_8 x_9^{1-r} \\
[x_3, x_2] &= x_8 x_9^{1-r} & [x_5, x_4] &= x_9 & x_4^2 &= x_6 \\
[x_4, x_2] &= x_5 x_7 x_8 x_9^{r} & [x_7, x_1] &= x_9 & x_6^2 &= x_8 \\
[x_4, x_3] &= x_7 & [x_7, x_2] &= x_9 & x_8^2 &= x_9 \\
[x_5, x_1] &= x_7 & x_9^2 &= x_4
\end{align*}
\]

Remark 1 about power commutator presentations applies here also. Both of these groups have order 2\(^9\) and 2-class 5. By looking at their derived series we deduce

**Proposition 3.** The fields \( k = \mathbb{Q}(\sqrt{-1015}) \) and \( k = \mathbb{Q}(\sqrt{-1595}) \) have finite 2-class tower of length 3, i.e. \( k = k_0 \subset k_1 \subset k_2 \subset k_3 = k_{nr} \). In both cases we have \( \text{Gal}(k_1/k_0) \cong [2, 8] \), \( \text{Gal}(k_2/k_1) \cong [2, 2, 2] \) and \( \text{Gal}(k_3/k_2) \cong [2] \).
