**Abstract**  
We present in detail the calculation of the $O(\alpha_s^3)$ inclusive total cross section for the process $p\bar{p} \rightarrow t\bar{t}h$ in the Standard Model, at the Tevatron center-of-mass energy $\sqrt{s_H} = 2$ TeV. The next-to-leading order QCD corrections significantly reduce the renormalization and factorization scale dependence of the Born cross section. They slightly decrease or increase the Born cross section depending on the values of the renormalization and factorization scales.
1 Introduction

Among the most important goals of present and future colliders is the study of the electroweak symmetry breaking mechanism and the origin of fermion masses. If the introduction of one or more Higgs fields is responsible for the breaking of the electroweak symmetry, then at least one Higgs boson should be relatively light, and certainly in the range of energies of present (Tevatron) or future (LHC) hadron colliders. The present lower bounds on the Higgs boson mass from direct searches at LEP2 are $M_h > 114.1$ GeV (at 95% CL) [1] for the Standard Model (SM) Higgs boson, and $M_{h^0} > 91.0$ GeV and $M_{A^0} > 91.9$ GeV (at 95% CL, $0.5 < \tan \beta < 2.4$ excluded) [2] for the light scalar ($h^0$) and pseudoscalar ($A^0$) Higgs bosons of the minimal supersymmetric standard model (MSSM). At the same time, global SM fits to all available electroweak precision data indirectly point to the existence of a light Higgs boson, $M_h < 212 - 236$ GeV [3], while the MSSM requires the existence of a scalar Higgs boson lighter than about 130 GeV [4]. Therefore, the possibility of a Higgs boson discovery in the mass range around 115-130 GeV seems increasingly likely.

In this context, the Tevatron will play a crucial role and can potentially discover a Higgs boson in the mass range between the present experimental lower bound and about 180 GeV [5]. The dominant Higgs production modes at the Tevatron are gluon-gluon fusion ($gg \rightarrow h$) and the associated production with a weak boson ($q\bar{q} \rightarrow W h, Z h$). Because of small event rates and large backgrounds, the Higgs boson search in these channels is extremely difficult, requiring the highest possible luminosity. It is therefore important to investigate all possible production channels, in the effort to fully exploit the range of opportunities offered by the available statistics.

Recently, attention has been drawn to the possibility of detecting a Higgs signal in association with a pair of top-antitop quarks at the Tevatron, i.e. in $p\bar{p} \rightarrow tt h$ [6]. This production mode can play a role over most of the Higgs mass range accessible at the Tevatron. Although it has a small event rate, $\sim 1 - 5$ fb for a SM-like Higgs boson, and even lower for an MSSM Higgs boson, the signature ($W^+ W^- b\bar{b} b\bar{b}$) is quite spectacular. Furthermore, at the Tevatron, after fully reconstructing both top quarks, the shape of the invariant mass distribution of the remaining $b\bar{b}$ pair is quite different for the signal and for the background. The statistics is too low to allow any direct measurement of the top-quark Yukawa coupling, but recent studies [7] indicate that this channel can reduce the luminosity required for the discovery of a SM-like Higgs boson at Run II of the Tevatron by as much as 15-20%.

The total cross section for $p\bar{p} \rightarrow tt h$ has been known at tree-level for quite some time [8]. As for any other hadronic process, next-to-leading (NLO) QCD corrections are expected to be important and are crucial in order to reduce the dependence of the cross section on the renormalization and factorization scales. Preliminary indications of the magnitude of the NLO QCD corrections can be obtained in the framework of the Effective Higgs Approximation (EHA), where terms of order $M_h/\sqrt{s}$ and $M_h/m_t$ are systematically neglected in the computation [9]. This approximation correctly reproduces the collinear bremsstrahlung of the Higgs boson from
the heavy top quarks. However, we expect the EHA to be more reliable at the LHC center-of-mass energies, for which it was originally proposed, than at the Tevatron center-of-mass energies. We will briefly discuss the predictions of the EHA for \( p\bar{p} \rightarrow t\bar{t}h \) in Sec. 6.

We also notice that QCD corrections to the associated production of a Higgs boson with a pair of \( b\bar{b} \) quarks, which is dominated by the \( gg \rightarrow b\bar{b}h \) channel, have been computed in the limit of large \( M_h \) [10], by resuming the leading \( \ln(M_h/m_t) \) terms. However this result cannot be applied to the \( t\bar{t}h \) production of a relatively light Higgs boson at the Tevatron, both because the ratio \( M_h/m_t \) is of \( \mathcal{O}(1) \) and does not justify the large \( M_h \) limit, and because the \( gg \) channel is negligible for \( t\bar{t}h \) production at the Tevatron.

In this paper we present in detail the calculation of the NLO inclusive total cross section for \( p\bar{p} \rightarrow t\bar{t}h \), \( \sigma_{NLO}(p\bar{p} \rightarrow t\bar{t}h) \), in the Standard Model, at the Tevatron center-of-mass energy. For \( p\bar{p} \) collisions at hadronic center-of-mass energy \( \sqrt{s_H} = 2 \text{ TeV} \), more than 95% of the tree-level cross section comes from the sub-process \( q\bar{q} \rightarrow t\bar{t}h \). Therefore, we include only the \( q\bar{q} \rightarrow t\bar{t}h \) channel when computing the tree-level total cross section, and we calculate the NLO total cross section by adding the complete set of virtual and real \( \mathcal{O}(\alpha_s) \) corrections to \( q\bar{q} \rightarrow t\bar{t}h \).

The Feynman diagrams contributing to \( q\bar{q} \rightarrow t\bar{t}h \) at lowest order are shown in Fig. 1, while examples of \( \mathcal{O}(\alpha_s) \) virtual and real corrections are given in Figs. 2-6. The main challenge in the calculation of the \( \mathcal{O}(\alpha_s) \) virtual corrections comes from the presence of pentagon diagrams with several massive external and internal particles. We have calculated the corresponding pentagon scalar integrals as linear combinations of scalar box integrals using the method of Ref. [11]. The real corrections are computed using the phase space slicing method, in both the double [12, 13] and single [14–16] cutoff approach. This is the first application of the single cutoff phase space slicing approach to a cross section involving more than one massive particle in the final state.

Numerical results for our calculation of \( \sigma_{NLO}(p\bar{p} \rightarrow t\bar{t}h) \) at the hadronic center-of-mass energy \( \sqrt{s_H} = 2 \text{ TeV} \) have been presented in [17]. An independent calculation of the NLO total cross section for \( p\bar{p} \rightarrow t\bar{t}h \) has been performed by Beenakker et al. [18]. The numerical results of both calculations have been compared and they are found to be in very good agreement. The \( \mathcal{O}(\alpha_s) \) corrections to the sub-process \( gg \rightarrow t\bar{t}h \) are, however, crucial for determining \( \sigma_{NLO}(pp \rightarrow t\bar{t}h) \) at the LHC, since \( pp \) collisions at \( \sqrt{s_H} = 14 \text{ TeV} \) are dominated by the gluon-gluon initial state. Results for the LHC are presented elsewhere [18, 19].
The outline of our paper is as follows. In Sec. 2 we summarize the general structure of the NLO cross section, and proceed in Secs. 3 and 4 to present the details of the calculation of both the virtual and real parts of the NLO QCD corrections. In Sec. 5 we explicitly show the factorization of the initial-state singularities into the quark distribution functions, and finally summarize our result for the NLO inclusive total cross section for $p\bar{p} \rightarrow t\bar{t}h$ at the Tevatron in Eqs. (33) and (34). Numerical results for the total cross section are presented in Sec. 6. Explicit analytic results for the scalar pentagon and the infrared-singular box integrals are presented in Appendices A and B. Appendix C contains a collection of soft phase space integrals that are used in the calculation of the real $O(\alpha_s)$ corrections to $q\bar{q} \rightarrow t\bar{t}h$ with the double cutoff phase space slicing method. Finally, in Appendix D we give the explicit structure of the real gluon emission color ordered amplitudes that are used in the calculation of the real $O(\alpha_s)$ corrections to $q\bar{q} \rightarrow t\bar{t}h$ with the single cutoff phase space slicing method.

2 General Framework

The inclusive total cross section for $p\bar{p} \rightarrow t\bar{t}h$ at $O(\alpha^3_s)$ can be written as:

$$\sigma_{NLO}(p\bar{p} \rightarrow t\bar{t}h) = \sum_{ij} \int dx_1 dx_2 F_i^p(x_1, \mu) F_j^\bar{p}(x_2, \mu) \hat{\sigma}^{ij}_{NLO}(x_1, x_2, \mu) ,$$

(1)

where $F_i^p$ are the NLO parton distribution functions (PDF) for parton $i$ in a proton/antiproton, defined at a generic factorization scale $\mu_f = \mu$, and $\hat{\sigma}^{ij}_{NLO}$ is the $O(\alpha^3_s)$ parton-level total cross section for incoming partons $i$ and $j$, composed of the two channels $qq$, $gg \rightarrow t\bar{t}h$, and renormalized at an arbitrary scale $\mu_r$ which we also take to be $\mu_r = \mu$. Throughout this paper we will always assume the factorization and renormalization scales to be equal, $\mu_r = \mu_f = \mu$. The partonic center-of-mass energy squared, $s$, is given in terms of the total hadronic center-of-mass energy squared, $s_h$, by $s = x_1 x_2 s_h$. As explained in the introduction, we consider only the $q\bar{q} \rightarrow t\bar{t}h$ channel, summed over all light quark flavors, and neglect the $gg \rightarrow t\bar{t}h$ channel, since the $gg$ initial state is numerically irrelevant at the Tevatron.

We write the NLO parton-level total cross section $\hat{\sigma}^{ij}_{NLO}(x_1, x_2, \mu)$ as:

$$\hat{\sigma}^{ij}_{NLO}(x_1, x_2, \mu) = \alpha_s^2(\mu) \left\{ f_{LO}^{ij}(x_1, x_2) + \frac{\alpha_s(\mu)}{4\pi} F_{NLO}^{ij}(x_1, x_2, \mu) \right\}$$

(2)

$$\equiv \hat{\sigma}^{ij}_{LO}(x_1, x_2, \mu) + \delta\hat{\sigma}^{ij}_{NLO}(x_1, x_2, \mu) ,$$

where $\alpha_s(\mu)$ is the strong coupling constant renormalized at the arbitrary scale $\mu_r = \mu$, $\hat{\sigma}^{ij}_{LO}(x_1, x_2, \mu)$ is the $O(\alpha^2_s)$ Born cross section, and $\delta\hat{\sigma}^{ij}_{NLO}(x_1, x_2, \mu)$ consists of the $O(\alpha_s)$ corrections to the Born cross section, including the effects of mass factorization (see Sec. 5).

The Born cross section to $q\bar{q} \rightarrow t\bar{t}h$ is given by [20]:

$$\hat{\sigma}_{LO}^{qq}(x_1, x_2, \mu) = \frac{\alpha_s^2(\mu)}{27\pi s} \left( \frac{m_t}{v} \right)^2 \int_{x_h^{\min}}^{x_h^{\max}} dx_h \left\{ \frac{4\bar{\beta}}{x_h^2 - \beta^2} \left( 1 + \frac{2m_t^2}{s} \right) \left( \frac{4m_t^2 - M_h^2}{s} \right) + \right\}$$

(3)

\[3\]
\[
\left[ x_h + 2 \left( \frac{4m_t^2 - M_h^2}{s} \right) + \frac{2}{x_h} \left( \frac{4m_t^2 - M_h^2}{s} \right) \left( 2m_t^2 - M_h^2 \right) \right] \frac{8m_t^2}{s x_h} \ln \left( \frac{x_h + \beta}{x_h - \beta} \right) ,
\]

where \( x_h = 2E_h/\sqrt{s} \), \( E_h \) is the Higgs boson energy in the \( q \bar{q} \) center-of-mass frame, \( x_h^{\text{min}} = 2M_h/\sqrt{s} \), \( x_h^{\text{max}} = 1 - 4m_t^2/s + M_h^2/s \), and we have introduced:

\[
\hat{\beta} = \left( \frac{\left[ x_h^{\text{min}} \right]}{\left[ x_h^{\text{max}} - x_h + 4m_t^2/s \right]} \right)^{1/2} .
\]

Moreover, we have defined the Yukawa coupling of the top quark to be \( g_t = m_t/v \), where \( v = (G_F \sqrt{2})^{-1/2} \) is the vacuum expectation value of the SM Higgs boson, given in terms of the Fermi constant \( G_F \).

The NLO QCD contribution, \( \delta \hat{\sigma}_{NLO}^{ij}(x_1, x_2, \mu) \), contains both virtual and real \( \mathcal{O}(\alpha_s) \) corrections to the lowest-order cross section and can be written as the sum of two terms:

\[
\delta \hat{\sigma}_{NLO}^{ij}(x_1, x_2, \mu) = \int d(PS_3) \sum |A_{\text{virt}}(ij \rightarrow t\bar{t}h)|^2 + \int d(PS_4) \sum |A_{\text{real}}(ij \rightarrow t\bar{t}h + g)|^2 \\
= \delta_{\text{virt}}^{ij}(x_1, x_2, \mu) + \delta_{\text{real}}^{ij}(x_1, x_2, \mu) ,
\]

(5)

where \( |A_{\text{virt}}(ij \rightarrow t\bar{t}h)|^2 \) and \( |A_{\text{real}}(ij \rightarrow t\bar{t}h + g)|^2 \) are respectively the squared matrix elements for the \( \mathcal{O}(\alpha_s^3) \) \( ij \rightarrow t\bar{t}h \) and \( ij \rightarrow t\bar{t}h + g \) processes, and \( \sum \) indicates that they have been averaged over the initial-state degrees of freedom and summed over the final-state ones. Moreover, \( d(PS_3) \) and \( d(PS_4) \) denote the integration over the corresponding three and four-particle phase spaces respectively. The first term in Eq. (5) represents the contribution of the virtual gluon corrections, while the second one is due to the real gluon emission. For the \( q \bar{q} \rightarrow t\bar{t}h \) sub-process, examples of \( \mathcal{O}(\alpha_s) \) virtual and real corrections are illustrated in Figs. [3][4] and their structure is separately explained in Secs. [3] and [4].

Finally, we observe that, in order to assure the renormalization scale independence of the total cross section at \( \mathcal{O}(\alpha_s^3) \), \( f_{NLO}^{ij}(x_1, x_2, \mu) \) in Eq.(2) must be of the form:

\[
f_{NLO}^{ij}(x_1, x_2, \mu) = f_1^{ij}(x_1, x_2) + \tilde{f}_1^{ij}(x_1, x_2) \ln \left( \frac{\mu^2}{s} \right) ,
\]

(6)

with \( \tilde{f}_1^{ij}(x_1, x_2) \) given by:

\[
\tilde{f}_1^{ij}(x_1, x_2) = 2 \left\{ 4\pi b_0 f_{LO}^{ij}(x_1, x_2) - \sum_k \left[ \int_0^1 dz_1 P_{ik}(z_1) f_{LO}^{kj}(x_1 z_1, x_2) \right] \right\} ,
\]

(7)

where \( \rho = (2m_t + M_h)^2/s \), \( P_{ij}(z) \) denotes the lowest-order Altarelli-Parisi splitting function [21] of parton \( i \) into parton \( j \), when \( j \) carries a fraction \( z \) of the momentum of parton \( i \), (see e.g.
Sec. 4.1.2), and \( b_0 \) is determined by the one-loop renormalization group evolution of the strong coupling constant \( \alpha_s \):

\[
\frac{d\alpha_s(\mu)}{d \ln(\mu^2)} = -b_0 \alpha_s^2 + \mathcal{O}(\alpha_s^3) \quad , \quad b_0 = \frac{1}{4\pi} \left( \frac{11}{3} N - \frac{2}{3} n_{lf} \right) ,
\]

(8)

with \( N = 3 \), the number of colors, and \( n_{lf} = 5 \), the number of light flavors. The origin of the terms in Eq. (7) will become manifest in Secs. 3 and 4, when we describe in detail the calculation of both virtual and real \( \mathcal{O}(\alpha_s) \) corrections to \( q\bar{q} \to t\bar{t}h \).

\[\begin{align*}
q_1 &+ \bar{q}_2 \to t(p_t) + \bar{t}(p'_t) + h(p_h) , \quad (9) \\
\sum |A_{\text{virt}}|^2 = \sum_i \sum (A_{LO}^i A_{D_i}^* + A_{LO}^{i*} A_{D_i}) = \sum_i \sum 2 \mathcal{R} \epsilon \left( A_{LO}^{i*} A_{D_i}^* \right) , \quad (10)
\end{align*}\]
Figure 3: $\mathcal{O}(\alpha_s)$ virtual corrections: vertex diagrams $V^{(1,2)}_1-V^{(1,2)}_6$. 
Figure 4: $\mathcal{O}(\alpha_s)$ virtual corrections: box diagrams $B_1$, $B_2^{(1,2)}$ and $B_3^{(1-4)}$. 
where the index $i$ runs over the set of all virtual diagrams, and $\mathcal{A}^d_{LO}$ denotes the tree-level amplitude for $q\bar{q} \to t\bar{b}$ calculated in $d = 4 - 2\epsilon$ dimensions. The lowest order amplitude $\mathcal{A}^d_{LO}$ must be computed to $O(\epsilon^2)$ in order to properly account for both the singular and finite contributions generated by the interference of $\mathcal{A}^d_{LO}$ with the single and double poles present in the virtual amplitudes $\mathcal{A}_D$. In what follows, we denote by $\mathcal{A}^d_{LO}$ the lowest order amplitude to $O(\epsilon^0)$, i.e. calculated in $d=4$ dimensions. Also, in the following sections, the contribution of a given diagram or set of diagrams to $\hat{\sigma}_{q\bar{q}}^{\text{virt}}$ is always to be understood as the contribution of the corresponding term in the sum in Eq. (10).

The calculation of the virtual diagrams has been performed using dimensional regularization, always in $d = 4 - 2\epsilon$ dimensions. The diagrams have been evaluated using FORM [22] and Maple, and all tensor integrals have been reduced to linear combinations of a fundamental set of scalar one-loop integrals using standard techniques [23]. The scalar integrals which give rise to either ultraviolet (UV) or infrared (IR) singularities have been computed analytically, while finite scalar integrals have been evaluated using standard packages [24].

Self-energy and vertex diagrams contain both IR and UV divergences. The UV divergences are renormalized by introducing a suitable set of counterterms. Since the cross section is a renormalization group invariant, we only need to renormalize the wave function of the external fields, the top-quark mass, and the coupling constants. We discuss the renormalization of the UV singularities of the virtual cross section in Sec. 3.1.

Box and pentagon diagrams are ultraviolet finite, but have infrared singularities. The IR poles in the $O(\alpha_s)$ virtual corrections are eventually canceled by analogous singularities in the $O(\alpha_s)$ real corrections to the tree-level cross section. We discuss the structure of the IR
singularities of the virtual cross section in Sec. 3.2. The structure of the IR singularities of the real cross section will be the subject of Secs. 4.1 and 4.2.

The calculation of many of the box scalar integrals and in particular of the pentagon scalar integrals are extremely laborious, due to the large number of massive particles present in the final state and in the loop. We have evaluated the necessary pentagon scalar integrals (one for diagram $P_1$ and one for diagram $P_2$), using the method of Ref. [11], which allows the reduction of a scalar five-point function to a sum of five scalar four-point functions, plus terms of $O(\epsilon)$ which can be neglected. Since this is a crucial ingredient of this calculation, we will explain in detail in Appendix A how the method of Ref. [11] has been applied to our case. The IR-divergent box scalar integrals are also collected in Appendix B.

3.1 UV singularities and counterterms

The UV singularities of the $O(\alpha_s^3)$ total cross section originate from self-energy and vertex virtual corrections. These singularities are renormalized by introducing counterterms for the wave function of the external fields ($\delta Z_2^{(q)}$, $\delta Z_2^{(t)}$), the top-quark mass ($\delta m_t$), and the coupling constants ($\delta g_t$, $\delta Z_{\alpha_s}$). If we denote by $\Delta_{UV}(S_i^{(1,2)})$ and $\Delta_{UV}(V_i^{(1,2)})$ the UV-divergent contribution of each self-energy ($S_i^{(1,2)}$) or vertex diagram ($V_i^{(1,2)}$) to the virtual amplitude squared (see Eq. (10)), we can write the UV-singular part of the total virtual amplitude squared as:

$$\sum |A_{virt}^{UV}|^2 = \sum |A_{LO}|^2 \left\{ \sum_{i=1}^{2} \Delta_{UV}(S_i^{(1)} + S_i^{(2)}) + \sum_{i=1}^{6} \Delta_{UV}(V_i^{(1)} + V_i^{(2)}) \right\} + 2 \left[ \left( \delta Z_2^{(q)} \right)_{UV} + \left( \delta Z_2^{(t)} \right)_{UV} + \frac{\delta m_t}{m_t} + \delta Z_{\alpha_s} \right].$$

As described earlier, we denote by $|A_{LO}|^2$ the matrix element squared of the tree-level amplitude for $q\bar{q} \rightarrow t\bar{t}h$, computed in $d = 4$ dimensions. We also notice that, in writing Eq. (11), we have included in the top-quark self-energy the top-mass counterterm, and we have used the fact that the Yukawa-coupling counterterm coincides with the top-mass counterterm.

The UV-divergent contributions due to the individual diagrams are explicitly given by:

$$\Delta_{UV} \left( S_1^{(1)} + S_1^{(2)} \right) = \frac{\alpha_s}{2\pi} N_t \left( \frac{N}{2} - \frac{1}{2N} \right) \left( \frac{1}{\epsilon_{UV}} \right),$$

$$\Delta_{UV} \left( S_2^{(1)} + S_2^{(2)} \right) = \frac{\alpha_s}{2\pi} \left[ N_s \left( \frac{5}{3} N - \frac{2}{3} n_{lf} \right) - N_t^2 \frac{2}{3} \right] \left( \frac{1}{\epsilon_{UV}} \right),$$

$$\Delta_{UV} \left( V_1^{(1)} + V_1^{(2)} \right) = \frac{\alpha_s}{2\pi} N_s \left( -\frac{1}{2N} \right) \left( \frac{1}{\epsilon_{UV}} \right),$$

$$\Delta_{UV} \left( V_2^{(1)} + V_2^{(2)} \right) = \frac{\alpha_s}{2\pi} N_s \left( \frac{N}{2} \right) \left( \frac{3}{\epsilon_{UV}} \right),$$

$$\Delta_{UV} \left( V_3^{(1)} + V_3^{(2)} \right) = \frac{\alpha_s}{2\pi} N_t \left( -\frac{1}{2N} \right) \left( \frac{1}{\epsilon_{UV}} \right),$$

(12)
\[ \Delta_{UV} \left( V_4^{(1)} + V_4^{(2)} \right) = \frac{\alpha_s}{2\pi} N_t \left( \frac{N}{2} - \frac{1}{2N} \right) \left( \frac{4}{\epsilon_{UV}} \right), \]
\[ \Delta_{UV} \left( V_5^{(1)} + V_5^{(2)} \right) = \frac{\alpha_s}{2\pi} N_t \left( \frac{N}{2} - \frac{1}{2N} \right) \left( \frac{4}{\epsilon_{UV}} \right), \]
\[ \Delta_{UV} \left( V_6^{(1)} + V_6^{(2)} \right) = 0, \]

where \( N_s \) and \( N_t \) are standard normalization factors defined as:

\[ N_s = \left( \frac{4\pi\mu^2}{s} \right)^\epsilon \Gamma(1 + \epsilon), \quad N_t = \left( \frac{4\pi\mu^2}{m_t^2} \right)^\epsilon \Gamma(1 + \epsilon). \] (13)

Moreover we define the needed counterterms according to the following convention. For the external fields, we fix the wave-function renormalization constants of the external fields \( Z_2^{(i)} = 1 + \delta Z_2^{(i)}, \ i = q, t \) using on-shell subtraction, i.e.:

\[ \left( \delta Z_2^{(q)} \right)_{UV} = -\left( \frac{\alpha_s}{4\pi} \right) N_s \left( \frac{N}{2} - \frac{1}{2N} \right) \left( \frac{1}{\epsilon_{UV}} \right), \]
\[ \left( \delta Z_2^{(t)} \right)_{UV} = -\left( \frac{\alpha_s}{4\pi} \right) N_t \left( \frac{N}{2} - \frac{1}{2N} \right) \left( \frac{1}{\epsilon_{UV}} + 4 \right). \] (14)

We notice that both \( \delta Z_2^{(q)} \) and \( \delta Z_2^{(t)} \), as well as some of the vertex corrections \( V^{(1,2)} \), have also IR singularities. In this section we limit the discussion to the UV singularities only, while the IR structure of these terms will be given explicitly in Sec. 3.2.

We define the subtraction condition for the top-quark mass \( m_t \) in such a way that \( m_t \) is the pole mass, in which case the top-mass counterterm is given by:

\[ \frac{\delta m_t}{m_t} = -\left( \frac{\alpha_s}{4\pi} \right) N_t \left( \frac{N}{2} - \frac{1}{2N} \right) \left( \frac{3}{\epsilon_{UV}} + 4 \right). \] (15)

This counterterm has to be used twice: to renormalize the top-quark mass, in diagrams \( S_1^{(1)} \) and \( S_1^{(2)} \), and to renormalize the top-quark Yukawa coupling. As we already noted, \( \Delta_{UV}(S_1^{(1)} + S_1^{(2)}) \) in Eq. (12) already includes the top-mass counterterm.

Finally, for the renormalization of \( \alpha_s \) we use the \( \overline{MS} \) scheme, modified to decouple the top quark. The first \( n_{lf} \) light flavors are subtracted using the \( \overline{MS} \) scheme, while the divergences associated with the top-quark loop are subtracted at zero momentum:

\[ \delta Z_{\alpha_s} = \left( \frac{\alpha_s}{4\pi} \right) (4\pi)^\epsilon \Gamma(1 + \epsilon) \left[ \left( \frac{2}{3} n_{lf} - \frac{11}{3} N \right) \frac{1}{\epsilon_{UV}} + \frac{2}{3} \left( \frac{1}{\epsilon_{UV}} + \ln \left( \frac{\mu^2}{m_t^2} \right) \right) \right], \] (16)

such that, in this scheme, the renormalized strong coupling constant \( \alpha_s \) evolves with \( n_{lf} = 5 \) light flavors.
It is easy to verify that the sum of all the UV-singular contributions as given in Eq. (11) is finite. We also notice that the left over renormalization scale dependence, due to the mismatch between the renormalization scale dependence of \( \Delta_{UV}(S_2) \) and \( \delta(Z_{\alpha_s}) \), is given by:

\[
\sum |A_{LO}|^2 \Delta_s(\mu) \left( -\frac{2}{3} m_f + \frac{11}{3} N \right) \ln \left( \frac{\mu^2}{s} \right),
\]

and corresponds exactly to the first term of Eq. (10), as predicted by renormalization group arguments.

### 3.2 IR singularities

This section describes the structure of the IR singularities originating from the \( \mathcal{O}(\alpha_s) \) virtual corrections. The virtual IR singularities come from the following set of diagrams: vertex diagrams \( V_1^{(1,2)} \) and \( V_2^{(1,2)} \), box diagrams \( B_2^{(1,2)} \), box diagrams \( B_3^{(1-4)} \), pentagon diagrams \( P_1 \) and \( P_2 \), and from the wave function renormalization of the external fields, \( \delta Z_2^{(q)} \) and \( \delta Z_2^{(t)} \). The IR-singular part of the total virtual amplitude squared is then of the form:

\[
\sum |A_{virt}|^2 = \sum |A_{LO}|^2 \left\{ \Delta_{IR} \left[ (V_1^{(1)} + V_1^{(2)}) + \Delta_{IR} \left[ (V_2^{(1)} + V_2^{(2)}) + (\delta Z_2^{(q)})_{IR} + (\delta Z_2^{(t)})_{IR}

where $N_s$ and $N_t$ are given in Eq. (13). Moreover, we have introduced the following kinematic invariants:

$$s = s_{q\bar{q}} = 2q_1 \cdot q_2, \quad s_{t\bar{t}} = 2p_t \cdot p'_t, \quad s_{q_1 \cdot p_t}, \quad s_{q_2 \cdot p_t}, \quad s_{q \cdot p_t'}, \quad s_{q \cdot p_t},$$

and we have defined

$$\beta_{t} = \sqrt{1 - \frac{4m_t^2}{(p_t + p'_t)^2}},$$

$$\Lambda_{t} = \ln \left( \frac{1 + \beta_{t}}{1 - \beta_{t}} \right).$$

Substituting the explicit expression for the IR-divergent contributions given in Eq. (19) into Eq. (18) yields:

$$\sum |A_{IR}^R|^2 = \left( \frac{\alpha_s}{2\pi} \right) N_t \sum |A_{LO}|^2 \left\{ \frac{X_{virt}}{\epsilon^2_{IR}} + \frac{X_{virt}}{\epsilon_{IR}} + \delta_{IR} \right\},$$

where

$$X_{virt}^{-2} = - \left( N - \frac{1}{N} \right),$$

$$X_{virt}^{-1} = N \left[ - \frac{5}{2} + \ln \left( \frac{s_{q\bar{q}}}{m_t^2} \right) + \ln \left( \frac{s_{q\bar{q}}}{m_t^2} \right) \right]$$

$$+ \frac{1}{N} \left[ - \ln \left( \frac{s_{t\bar{t}}}{m_t^2} \right) + \frac{s_{t\bar{t}}}{2} \right] \Lambda_{t} - 2 \ln \left( \frac{s_{q\bar{q}} s_{t\bar{t}}}{s_{q\bar{q}} s_{t\bar{t}}} \right),$$

while $\delta_{IR}^{virt}$ is a finite term that derives from having factored out a common factor $N_t$, and is given by:

$$\delta_{IR}^{virt} = \left( N - \frac{1}{N} \right) \left[ \frac{3}{2} \ln \left( \frac{s}{m_t^2} \right) \right] + \frac{1}{N} \left[ \frac{1}{2} \ln^2 \left( \frac{s}{m_t^2} \right) \right].$$

In Secs. 4.1.1 and 4.2.3, we will show how the IR singularities of the real cross section exactly cancel the IR poles of the virtual cross section (see Eqs. (33)-(34) and Eqs. (77)-(78)), as predicted by the Bloch-Nordsieck [26] and Kinoshita-Lee-Nauenberg [27, 28] theorems.

### 4 Real Corrections

The $O(\alpha_s)$ corrections to $q\bar{q} \to t\bar{t}h$ due to real gluon emission (see Fig. 3) give origin to IR singularities which cancel exactly the analogous singularities present in the $O(\alpha_s)$ virtual corrections (see Sec. 3.2). These singularities can be either of soft or collinear nature and can
be conveniently isolated by slicing the $q\bar{q} \to t\bar{t}h + g$ phase space into different regions defined by suitable cutoffs, a method which goes under the general name of Phase Space Slicing (PSS). The dependence on the arbitrary cutoff(s) introduced in the process is not physical, and, in fact, cancels at the level of the total real gluon emission hadronic cross section, i.e. in $\sigma_{\text{real}}$, the real part of $\sigma_{\text{NLO}}$. This constitutes an important check of the calculation.

We have calculated the cross section for the process

$$q(q_1) + \bar{q}(q_2) \to t(p_t) + \bar{t}(p'_t) + h(p_h) + g(k)$$

(25)

using two different implementations of the PSS method which we call the two-cutoff and one-cutoff method respectively, depending on the number of cutoffs introduced. The two-cutoff implementation of the PSS method has been originally developed to study QCD corrections to dihadron production [12] and has since then been applied to a variety of processes. A nice review has recently appeared [13] to which we refer for more extensive references and details. The one-cutoff PSS method has been developed for massless quarks in Ref. [14,15] and extended to the case of massive quarks in Ref. [16].

In the next two sections we explain in detail how we have applied the PSS method to our case, using the two-cutoff implementation in Sec. 4.1 and the one-cutoff implementation in Sec. 4.2. The results for $\sigma_{\text{real}}$ obtained using PSS with one or two cutoffs agree within the statistical errors. In spite of the fact that both methods are realizations of the general idea of phase space slicing, they have very different characteristics and finding agreement between the two represents an important check of our calculation.

4.1 Phase Space Slicing method with two cutoffs

The general implementation of the PSS method using two cutoffs proceeds in two steps. First, by introducing an arbitrary small soft cutoff $\delta_s$ we separate the overall integration of the $q\bar{q} \to t\bar{t}h + g$ phase space into two regions, according to whether the energy of the gluon is soft, i.e. $E_g \leq \delta_s \sqrt{s}/2$, or hard, i.e. $E_g > \delta_s \sqrt{s}/2$. The partonic real cross section of Eq. (5) can then be written as:

$$\hat{\sigma}^{q\bar{q}}_{\text{real}} = \hat{\sigma}_{\text{soft}} + \hat{\sigma}_{\text{hard}},$$

(26)

where $\hat{\sigma}_{\text{soft}}$ is obtained by integrating over the soft region of the gluon phase space, and contains all the IR soft divergences of $\hat{\sigma}^{q\bar{q}}_{\text{real}}$. To isolate the remaining collinear divergences from $\hat{\sigma}_{\text{hard}}$, we further split the integration over the hard gluon phase space according to whether the gluon is ($\hat{\sigma}_{\text{hard/coll}}$) or is not ($\hat{\sigma}_{\text{hard/non-coll}}$) emitted within an angle $\theta$ from the initial-state massless quarks such that $(1 - \cos \theta) < \delta_c$, for an arbitrary small collinear cutoff $\delta_c$:

$$\hat{\sigma}_{\text{hard}} = \hat{\sigma}_{\text{hard/coll}} + \hat{\sigma}_{\text{hard/non-coll}}.$$  

(27)

The hard non-collinear part of the real cross section, $\hat{\sigma}_{\text{hard/non-coll}}$, is finite and can be computed numerically, using standard Monte-Carlo techniques. In the soft and collinear regions, the
integration over the phase space of the emitted gluon can be performed analytically, thus allowing us to isolate the IR collinear divergences of $\hat{\sigma}_{\text{soft}}$. More details on the calculation of $\hat{\sigma}_{\text{soft}}$ and $\hat{\sigma}_{\text{hard}}$ are given in Sec. 4.1.1 and Sec. 4.1.2, respectively. The cross sections describing soft, collinear and IR-finite gluon radiation depend on the two arbitrary parameters, $\delta_s$ and $\delta_c$. However, in the real hadronic cross section $\sigma_{\text{real}}$, after mass factorization, the dependence on these arbitrary cutoffs cancels, as will be explicitly shown in Sec. 3.

4.1.1 Soft gluon emission

The soft region of the $q\bar{q} \to t\bar{t}h + g$ phase space is defined by requiring that the energy of the gluon satisfies:

$$E_g < \delta_s \frac{\sqrt{s}}{2},$$

(28)

for an arbitrary small value of the soft cutoff $\delta_s$. In the limit when the energy of the gluon becomes small, i.e. in the soft limit, the matrix element squared for the real gluon emission, $\sum |A_{\text{real}}|^2$, assumes a very simple form, i.e. it factorizes into the Born matrix element squared times an eikonal factor $\Phi_{\text{eik}}$:

$$\sum |A_{\text{real}}(q\bar{q} \to t\bar{t}h + g)|^2 \overset{soft}{\longrightarrow} (4\pi\alpha_s) \sum |A_{\text{LO}}|^2 \Phi_{\text{eik}},$$

(29)

where the eikonal factor is given by:

$$\Phi_{\text{eik}} = \frac{N}{2} \left[ -\frac{m_t^2}{(p_t \cdot k)^2} - \frac{m_t^2}{(p'_t \cdot k)^2} + \frac{s_{qt}}{(q_1 \cdot k)(p_t \cdot k)} + \frac{s_{q\bar{t}}}{(q_2 \cdot k)(p'_t \cdot k)} \right]$$

$$+ \frac{1}{2N} \left[ \frac{m_t^2}{(p_t \cdot k)^2} + \frac{m_t^2}{(p'_t \cdot k)^2} - \frac{s}{(q_1 \cdot k)(q_2 \cdot k)} - \frac{s_{ti}}{(p_t \cdot k)(p'_t \cdot k)} \right]$$

$$+ 2 \left( -\frac{s_{qt}}{(q_1 \cdot k)(p_t \cdot k)} + \frac{s_{q\bar{t}}}{(q_1 \cdot k)(p'_t \cdot k)} + \frac{s_{qt}}{(q_2 \cdot k)(p_t \cdot k)} - \frac{s_{q\bar{t}}}{(q_2 \cdot k)(p'_t \cdot k)} \right).$$

Moreover, in the soft region the $q\bar{q} \to t\bar{t}h + g$ phase space also factorizes as:

$$d(PS_4)(q\bar{q} \to t\bar{t}h + g) \overset{\text{soft}}{\longrightarrow} d(PS_4)(q\bar{q} \to t\bar{t}h) d(PS_g)_{\text{soft}}$$

(31)

$$= d(PS_3)(q\bar{q} \to t\bar{t}h) \frac{d^{(d-1)}k}{(2\pi)^{(d-1)}2E_g} \theta(\delta_s \frac{\sqrt{s}}{2} - E_g),$$

where $d(PS_g)_{\text{soft}}$ denotes the integration over the phase space of the soft gluon. The parton level soft cross section can then be written as:

$$\hat{\sigma}_{\text{soft}} = (4\pi\alpha_s) \mu^{2\epsilon} \int d(PS_3) \sum |A_{\text{LO}}|^2 \int d(PS_g)_{\text{soft}} \Phi_{\text{eik}}.$$

(32)

Since the contribution of the soft gluon is now completely factorized, we can perform the integration over $d(PS_g)_{\text{soft}}$ in Eq. 32 analytically, and extract the soft poles that will have
to cancel $X_{-2}^{\text{virt}}$ and $X_{-1}^{\text{virt}}$ of Eq. (23). The integration over the gluon phase space in Eq. (32) can be performed using standard techniques and we refer to Refs. [13,29] for more details. For sake of completeness, in Appendix C we give explicit results for the soft integrals used in our calculation.

Finally, the soft gluon contribution to $\hat{\sigma}_{\text{soft}}^{\text{real}}$ can be written as follows:

$$\hat{\sigma}_{\text{soft}} = \frac{\alpha_s}{2\pi} N_t \int d(PS_3) \sum |A_{LO}|^2 \left\{ \frac{X_{-2}^s}{\epsilon^2} + \frac{X_{-1}^s}{\epsilon} + NC_1^s + \frac{C_2^s}{N} \right\}, \quad (33)$$

where

$$X_{-2}^s = -X_{-2}^{\text{virt}}, \quad (34)$$

$$X_{-1}^s = -X_{-1}^{\text{virt}} - \left( N - \frac{1}{N} \right) \left[ \frac{3}{2} + 2\ln(\delta_s) \right], \quad \left( \frac{s_{t_1}^2}{m_t^2} \right)$$

$$C_1^s = \frac{3}{2} \ln \left( \frac{s}{\mu^2} \right) + 2\ln^2(\delta_s) - 2\ln(\delta_s) \left[ 1 + \frac{\frac{m_t^2}{s_{t_1}}}{s_{t_1}^2 s_q s_g} \right]$$

$$+ \frac{1}{2} \ln^2 \left( \frac{s}{m_t^2} \right) - \frac{\pi^2}{3} - \ln \left( \frac{s}{m_t^2} \right) \left[ \frac{5}{2} + \frac{\frac{s_{t_1}^2}{s_{t_1}^2 s_q s_g}}{\frac{s_{t_1}^2}{s_{t_1}^2 s_q s_g}} \right]$$

$$+ \frac{\Lambda_{t t}}{\beta_{t t}} + \frac{1}{2} \left[ F_{q t} + F_{q t} \right] + \left[ \frac{3}{2} + 2\ln(\delta_s) \right] \ln \left( \frac{\mu^2}{m_t^2} \right),$$

$$C_2^s = \frac{3}{2} \ln \left( \frac{s}{\mu^2} \right) - 2\ln^2(\delta_s) - 2\ln(\delta_s) \left[ -1 + \frac{s_{t_1}}{(2m_t^2 + s_{t_1}) \beta_{t t}} \Lambda_{t t} \right]$$

$$+ \ln \left( \frac{s}{\mu^2} \right) + 2\ln \left( \frac{s_{q t} s_{q g}}{s_{q t} s_{q g}} \right)$$

$$- \frac{1}{2} \ln^2 \left( \frac{s}{m_t^2} \right) + \frac{\pi^2}{3} - \ln \left( \frac{s}{m_t^2} \right) \left[ -\frac{5}{2} + \frac{s_{t_1}}{(2m_t^2 + s_{t_1}) \beta_{t t}} \Lambda_{t t} \right]$$

$$+ 2\ln \left( \frac{s_{q t} s_{q g}}{s_{q t} s_{q g}} \right) - \frac{\Lambda_{t t}}{\beta_{t t}}$$

$$+ \frac{2s_{t_1}}{(2m_t^2 + s_{t_1}) \beta_{t t}} \left[ \text{Li}_2 \left( \frac{2\beta_{t t}}{1 + \beta_{t t}} \right) + \frac{1}{4} \ln^2 \left( \frac{1 + \beta_{t t}}{1 - \beta_{t t}} \right) \right]$$

$$- F_{q t} + F_{q t} + F_{q t^2} - F_{q t} - \left[ \frac{3}{2} + 2\ln(\delta_s) \right] \ln \left( \frac{\mu^2}{m_t^2} \right),$$

while $N_t$ is defined in Eq. (13), and $\text{Li}_2$ denotes the dilogarithm as described in Ref. [30]. $\beta_{t t}$ and $\Lambda_{t t}$ are defined in Eq. (21), while for any initial parton $i$ and final parton $f$, the function $F_{i f}$ can be written as:

$$F_{i f} = \ln^2 \left( \frac{1 - \beta_f}{1 - \beta_f \cos \theta_{i f}} \right) - \frac{1}{2} \ln^2 \left( \frac{1 + \beta_f}{1 - \beta_f} \right)$$

$$+ 2\text{Li}_2 \left( \frac{-\beta_f (1 - \cos \theta_{i f})}{1 - \beta_f} \right) - 2\text{Li}_2 \left( -\frac{\beta_f (1 + \cos \theta_{i f})}{1 - \beta_f \cos \theta_{i f}} \right), \quad (35)$$

15
where \( \cos \theta_{if} \) is the angle between partons \( i \) and \( f \) in the center-of-mass frame of the initial state partons, and
\[
\beta_f = \sqrt{1 - \frac{m_i^2}{(p_f^0)^2}}, \quad 1 - \beta_f \cos \theta_{if} = \frac{s_{if}}{p_f^0 \sqrt{s}}.
\]

All the quantities in Eq. (35) can be expressed in terms of kinematic A l invariants, once we use \( s_{if} = 2p_i \cdot p_f \) together with:
\[
p_i^0 = \frac{s - \bar{s}_h + m_i^2}{2 \sqrt{s}} \quad \text{and} \quad p_i^0 = \frac{s - \bar{s}_h + m_i^2}{2 \sqrt{s}},
\]

where \( \bar{s}_h = (p_f + p_h)^2 \). As can be easily seen from Eqs. (23) and (34), the IR poles of the virtual corrections are exactly canceled by the corresponding singularities in the soft gluon contribution. The remaining IR poles in \( \hat{\sigma}_{soft} \) will be canceled by the PDF counterterms as described in detail in Sec. [4].

### 4.1.2 Hard gluon emission

The hard region of the gluon phase space is defined by requiring that the energy of the emitted gluon is above a given threshold. As we discussed earlier this is expressed by the condition that
\[
E_g > \delta_s \frac{\sqrt{s}}{2},
\]
for an arbitrary small soft cutoff \( \delta_s \), which automatically assures that \( \hat{\sigma}_{hard} \) does not contain soft singularities. However, a hard gluon can still give origin to singularities when it is emitted at a small angle, i.e. collinear, to a massless incoming or outgoing parton. In order to isolate these divergences and compute them analytically, we further divide the hard region of the \( q\bar{q} \rightarrow t\bar{t}h + g \) phase space into a hard/collinear and a hard/non-collinear region, by introducing a second small collinear cutoff \( \delta_c \). The hard/non-collinear region is defined by the condition that both
\[
\frac{2q_1 \cdot k}{E_g \sqrt{s}} > \delta_c \quad \text{and} \quad \frac{2q_2 \cdot k}{E_g \sqrt{s}} > \delta_c
\]
are verified. The contribution from the hard/non-collinear region, \( \hat{\sigma}_{hard/non-coll} \), is finite and we compute it numerically by using standard Monte Carlo integration techniques.

In the hard/collinear region, one of the conditions in Eq. (39) is not satisfied and the hard gluon is emitted collinear to one of the incoming partons. In this region, the initial-state parton \( i \) (\( i = q, \bar{q} \)) is considered to split into a hard parton \( i' \) and a collinear gluon \( g \), \( i \to i'g \), with \( p_{i'} = z p_i \) and \( k = (1 - z)p_i \). The matrix element squared for \( ij \to t\bar{t}h + g \) factorizes into the Born matrix element squared and the Altarelli-Parisi splitting function for \( i \to i'g \), i.e.:
\[
\sum_i |A_{real}(ij \to t\bar{t}h + g)|^2 \xrightarrow{\text{collinear}} (4\pi \alpha_s) \sum_i \sum_j |A_{LO}(i'j \to t\bar{t}h)|^2 \frac{2P_{i'}(z)}{z s_{ig}},
\]

16
with \( s_{ig} = 2p_i \cdot k \). In our case:

\[
P_{ir}(z) = P_{qq}(z) = C_F \left( \frac{1 + z^2}{1 - z} - \epsilon(1 - z) \right)
\]

(41)
is the unregulated Altarelli-Parisi splitting function for \( q \to q + g \) at lowest order, including terms of \( \mathcal{O}(\epsilon) \), and \( C_F = (N^2 - 1)/2N \). Moreover, in the collinear limit, the \( q\bar{q} \to t\bar{t}h + g \) phase space also factorizes as:

\[
d(PS_1)(ij \to t\bar{t}h + g) \xrightarrow{\text{collinear}} d(PS_3)(i'j \to t\bar{t}h) \frac{z d^{(d-1)}k}{(2\pi)_{(d-1)}^2 E_g} \theta \left( E_g - \delta_s \frac{\sqrt{s}}{2} \right) \times
\]

(42)

\[
\theta(\cos \theta_{ig} - (1 - \delta_c))
\]

\[
d_{d=4-2\epsilon} \frac{\Gamma(1 - \epsilon)}{\Gamma(1 - 2\epsilon)} \frac{(4\pi)\epsilon}{16\pi^2} z \, dz \, ds_{ig} \left[ (1 - z) s_{ig} \right]^{-\epsilon} \theta \left( \frac{(1 - z)}{z} \delta_c \frac{\delta_c}{2} - s_{ig} \right),
\]

where the integration range for \( s_{ig} \) in the collinear region is given in terms of the collinear cutoff, and we have defined \( s' = 2p_{ir} \cdot p_j \). The integral over the collinear gluon degrees of freedom can then be performed separately, and this allows us to explicitly extract the collinear singularities of \( \hat{\sigma}_{\text{hard}} \). \( \hat{\sigma}_{\text{hard/coll}} \) turns out to be of the form \([33]([13])\):

\[
\hat{\sigma}_{\text{hard/coll}} = \frac{\alpha_s}{2\pi} \frac{\Gamma(1 - \epsilon)}{\Gamma(1 - 2\epsilon)} \left( \frac{4\pi \mu^2}{m_i^2} \right)^\epsilon \left( \frac{1}{\epsilon} \right) \delta_c^{-\epsilon} \times
\]

(43)

\[
\left\{ \int_0^{1-\delta_c} dz \left[ \frac{(1 - z)^2}{2z} \frac{s'}{m_i^2} \right]^{-\epsilon} P_{ir}(z) \hat{\sigma}_{\text{LO}}(i'j \to t\bar{t}h) + (i \leftrightarrow j) \right\}.
\]

The upper limit on the \( z \) integration ensures the exclusion of the soft gluon region. As usual, these initial-state collinear divergences are absorbed into the parton distribution functions as will be described in detail in the Sec. 3.

### 4.2 Phase Space Slicing method with one cutoff

An alternative way of isolating both soft and collinear singularities is to divide the phase space of the final state partons into two regions according to whether all partons can be resolved (the \( \text{hard} \) region) or not (the \( \text{infrared} \), or \( \text{ir} \), region). In the case of \( q\bar{q} \to t\bar{t}h + g \), the \( \text{hard} \) and \( \text{ir} \) regions are defined by whether the gluon is resolved or not. The emitted gluon is not resolved, and therefore considered \( \text{ir} \), when

\[
s_{ig} = 2p_i \cdot k < s_{\text{min}} \quad \text{, with} \quad i = q, \bar{q}, t, \bar{t},
\]

(44)

for an arbitrary small cutoff \( s_{\text{min}} \). Similarly to Eq. (27), the partonic real cross section can be written as the sum of two terms:

\[
\hat{\sigma}_{\text{qg}}^{\text{real}} = \hat{\sigma}_{\text{ir}} + \hat{\sigma}_{\text{hard}},
\]

(45)
where \( \sigma_{ir} \) includes both soft and collinear singularities, while \( \sigma_{hard} \) is finite. Following the general idea of PSS, we calculate \( \sigma_{ir} \) analytically, while we evaluate \( \sigma_{hard} \) numerically, using standard Monte Carlo integration techniques. Both \( \sigma_{ir} \) and \( \sigma_{hard} \) depend on the cutoff \( s_{min} \), but the hadronic real cross section, \( \sigma_{real} \), is cutoff independent, after mass factorization, as will be shown in Sec. 3.

In order to calculate \( \sigma_{ir} \) we apply the formalism developed in Refs. [14–16] as follows.

- We consider the crossed process \( h \to q\bar{q}t\bar{t} + g \) which is obtained from \( q\bar{q} \to t\bar{t}h + g \) by crossing all the initial state colored partons to the final state, while crossing the Higgs boson to the initial state. For a systematic extraction of the IR singularities within the one-cutoff method, we organize the amplitude for \( h \to q\bar{q}t\bar{t} + g \), \( \mathcal{A}^{h \to q\bar{q}t\bar{t} + g} \), in terms of colored ordered amplitudes [12]. Using the color decomposition:

\[
T^a_{c_1c_2}T^a_{c_3c_4} = \frac{1}{2} \left( \delta_{c_1c_2}\delta_{c_3c_4} - \frac{1}{N}\delta_{c_1c_2}\delta_{c_3c_4} \right),
\]

we write \( \mathcal{A}^{h \to q\bar{q}t\bar{t} + g} \) as the sum of four color ordered amplitudes \( \mathcal{A}_1, \ldots, \mathcal{A}_4 \) as follows:

\[
\mathcal{A}^{h \to q\bar{q}t\bar{t} + g} = ig_s \delta_{f_qf_{\bar{q}}} \delta_{f_tf_{\bar{t}}} \frac{1}{2} \left( \delta_{c_qc_t} T^a_{c_qc_t} A_1(p_t, p'_t, q_1, q_2, k) + T^a_{c_qc_t} \delta_{c_qc_t} A_2(p_t, p'_t, q_1, q_2, k) \right)
- \frac{1}{N} \delta_{c_qc_t} T^a_{c_qc_t} A_3(p_t, p'_t, q_1, q_2, k) - \frac{1}{N} T^a_{c_qc_t} \delta_{c_qc_t} A_4(p_t, p'_t, q_1, q_2, k) \right),
\]

where \( g_s = \sqrt{4\pi\alpha_s} \), while \((f_q, f_{\bar{q}}, f_t, f_{\bar{t}})\) and \((c_q, c_{\bar{q}}, c_t, c_{\bar{t}})\) denote the flavor and color indices of the various outgoing quarks. The amplitudes \( \mathcal{A}_i(p_t, p'_t, q_1, q_2, k) \) (for \( i = 1, 2, 3, 4 \)) correspond to the four possible independent color structures that arise in the \( h \to t\bar{t}q\bar{q} + g \) process, and each \( \mathcal{A}_i \) contains terms describing the emission of the gluon from a different pair of external quarks. We give the explicit expressions for the \( \mathcal{A}_i \) amplitudes in Appendix [13]. Due to this decomposition, the partonic cross section for \( h \to q\bar{q}t\bar{t} + g \) can be written in a very compact form:

\[
\hat{\sigma}^{h \to q\bar{q}t\bar{t} + g} = \int d(P S_b) \sum |\mathcal{A}^{h \to q\bar{q}t\bar{t} + g}|^2,
\]

with

\[
\sum |\mathcal{A}^{h \to q\bar{q}t\bar{t} + g}|^2 = \left( \frac{g_s^2 N}{2} \right) \left( \frac{N^2 - 1}{4} \right) \sum \left\{ |\mathcal{A}_1|^2 + |\mathcal{A}_2|^2 + \frac{1}{N^2} \left[ -2 |\mathcal{A}_3 + \mathcal{A}_4|^2 + |\mathcal{A}_3|^2 + |\mathcal{A}_4|^2 \right] \right\}.
\]

- Using the one-cutoff PSS method and the factorization properties of both the color ordered amplitudes \( \mathcal{A}_i \) and the gluon phase space in the soft/collinear limit, we extract the IR
singularities of $\hat{\sigma}^{h \to q\bar{q} \bar{t}t} \to q\bar{q} \bar{t}t$ into $\hat{\sigma}_{\text{soft}}^{h \to q\bar{q} \bar{t}t}$ and $\hat{\sigma}_{\text{coll}}^{h \to q\bar{q} \bar{t}t}$ as follows:

$$\hat{\sigma}_{\text{soft}}^{h \to q\bar{q} \bar{t}t} \to \hat{\sigma}_{\text{soft}}^{h \to q\bar{q} \bar{t}t} = \int d(PS_4) d(PS_g) \sum |A_{\text{soft}}^{h \to q\bar{q} \bar{t}t}|^2 , \quad (50)$$

$$\hat{\sigma}_{\text{coll}}^{h \to q\bar{q} \bar{t}t} \to \hat{\sigma}_{\text{coll}}^{h \to q\bar{q} \bar{t}t} = \int d(PS_4) d(PS_g) \sum |A_{\text{coll}}^{h \to q\bar{q} \bar{t}t}|^2 , \quad (51)$$

where we denote by $d(PS_g)_{\text{soft}}$ ($d(PS_g)_{\text{coll}}$) the phase space of the gluon in the soft (collinear) limit, while $\sum |A_{\text{soft}}^{h \to q\bar{q} \bar{t}t}|^2$ ($\sum |A_{\text{coll}}^{h \to q\bar{q} \bar{t}t}|^2$) represents the soft (collinear) limit of Eq. (49). The explicit calculation of $\hat{\sigma}_{\text{soft, coll}}^{h \to q\bar{q} \bar{t}t}$ is described in detail in Sections 4.2.1 and 4.2.2, respectively. The factorization of soft and collinear singularities for color ordered amplitudes has been discussed in the literature mainly for the leading color terms ($O(N)$). For our application of the one-cutoff PSS method, we will have to extend these results to the sub-leading color terms ($O(1/N)$).

- Finally, the IR singular contribution $\hat{\sigma}_{\text{ir}}$ in Eq. (13) consists of two terms:

$$\hat{\sigma}_{\text{ir}} = \hat{\sigma}_{\text{ir}} + \hat{\sigma}_{\text{crossing}} . \quad (52)$$

As described in detail in Sec. 4.2.3, $\hat{\sigma}_{\text{ir}}^t$ is obtained by crossing $q$ and $\bar{q}$ to the initial state and $h$ to the final state in the sum of $\hat{\sigma}_{\text{soft}}^{h \to q\bar{q} \bar{t}t}$ and $\hat{\sigma}_{\text{coll}}^{h \to q\bar{q} \bar{t}t}$, while $\hat{\sigma}_{\text{crossing}}$ corrects for the difference between the collinear gluon radiation from initial and final state partons [13], as will be discussed in detail in Sec. 3. As explicitly shown in Sec. 4.2.3, the IR singularities of $\hat{\sigma}_{\text{virt}}^{q\bar{q}}$ of Sec. 12 are exactly canceled by the corresponding singularities in $\hat{\sigma}_{\text{ir}}^t$. On the other hand, $\hat{\sigma}_{\text{crossing}}$ still contains collinear divergences that will be canceled by the PDF counterterms when the parton cross section is convoluted with the PDFs (see Sec. 3).

### 4.2.1 Soft gluon emission

We first consider the case of soft singularities, when, in the limit of $E_g \to 0$ (soft limit), one or more $s_{i\gamma} < s_{\text{min}}$ ($i = q, \bar{q}, t, \bar{t}$). Using the factorization properties of the color ordered amplitudes $A_i$ in the soft limit, the amplitude squared for $h \to q\bar{q} \bar{t}t + g$ can be written as:

$$\sum |A_{h \to q\bar{q} \bar{t}t}^{h \to q\bar{q} \bar{t}t}|^2 \to \sum |A_{\text{soft}}^{h \to q\bar{q} \bar{t}t}|^2 \to \left( g_s^2 N \right) \sum |A_{\text{LO}}^{h \to q\bar{q} \bar{t}t}|^2 \left\{ f_{q\bar{q}}(g) + f_{q\bar{t}}(g) \right. - \frac{1}{N^2} \left[ f_{q\bar{q}}(g) + f_{q\bar{q}}(g) - 2 \left( f_{q\bar{t}}(g) - f_{q\bar{t}}(g) - f_{q\bar{t}}(g) + f_{q\bar{t}}(g) \right) \right] , \quad (53)$$

where, for any pair of quarks $(a, b)$, the soft functions $f_{a\bar{b}}(g)$ are defined as:

$$f_{a\bar{b}}(g) = \frac{4s_{a\bar{b}}}{s_{a\bar{b}}s_{\gamma\gamma}} - \frac{4m_a^2}{s_{a\bar{b}}} - \frac{4m_b^2}{s_{a\bar{b}}} , \quad (54)$$
and, as before (see Eq. (20)),
\[ s_{ij} \equiv 2p_i \cdot p_j , \]
both for massless and massive quarks. \( A_{LO}^{h \rightarrow q\bar{q}t\bar{t}} \) is the tree level amplitude for the process \( h \rightarrow q\bar{q}t\bar{t} \) as given by Eq. (130). We note that Eq. (53) corresponds to the factorization property expressed in Eq. (29). Since, in the soft limit, the \( h \rightarrow q\bar{q}t\bar{t} + g \) phase space also factorizes, in analogy to Eq. (31), we can integrate out the soft gluon degrees of freedom and obtain the soft gluon part of the cross section for \( h \rightarrow q\bar{q}t\bar{t} + g \) as:
\[
\hat{\sigma}_{soft}^{h \rightarrow q\bar{q}t\bar{t}g} = \int d(PS_{4}) \sum |A_{LO}^{h \rightarrow q\bar{q}t\bar{t}}|^2 \left\{ S_{qt} + S_{qt} - \frac{1}{N^2} [S_{tt} + S_{qq} - 2 (S_{qt} - S_{qt} - S_{qt} + S_{qt})] \right\} ,
\]
(55)
where, for any pair of quarks \((a, b)\), the integrated soft functions \( S_{ab} \) are defined as:
\[
S_{ab} = \frac{g_s^2 N_c}{2} \int d(PS_g)_{soft}(a, b, g) f_{ab}(g) .
\]
(56)
In the one-cutoff PSS method, the explicit form of the soft gluon phase space integral is given by \[16\]:
\[
d(PS_g)_{soft}(a, b, g) = \left\{ \frac{16\pi^2}{\lambda \Gamma(1-\epsilon)} \left[ s_{ag} s_{bg} - m_b^2 s_{ag} - m_a^2 s_{bg} \right]^{-\epsilon} ds_{ag} ds_{bg} \times \theta(s_{ag} - s_{min})\theta(s_{bg} - s_{min}) \right\} ,
\]
(57)
where
\[
\lambda = s_{ab}^2 - 4m_a^2 m_b^2 ,
\]
and the integration boundaries for \( s_{ag} \) and \( s_{bg} \) vary accordingly to whether \( a \) and \( b \) are massive or massless quarks (see Ref. \[16\] for more details).

The explicit form of the integrated soft functions \( S_{ab} \) is obtained by carrying out the integration in Eq. (56). When \( a = q \) and \( b = \bar{q} \), i.e. when both quarks are massless, the integrated soft function \( S_{qq} \) is given by \[14\]:
\[
S_{qq} = \left( \frac{\alpha_s N_c}{2\pi} \right) \frac{1}{\Gamma(1-\epsilon)} \left( \frac{4\pi \mu^2}{s_{min}} \right)^{\epsilon} \left( \frac{1}{s^\epsilon} \right) \left( \frac{s}{s_{min}} \right)^{\epsilon} ,
\]
(59)
where, in our notation, \( s = s_{qq} \) is the parton center-of-mass energy (see Eq. (20)). On the other hand, when \( a = q, \bar{q} \) and \( b = t, \bar{t} \), i.e. when one quark is massless and the other is massive, the corresponding integrated soft functions are of the form \[14\]:
\[
S_{ab} = \left( \frac{\alpha_s N_c}{2\pi} \right) \frac{1}{\Gamma(1-\epsilon)} \left( \frac{4\pi \mu^2}{s_{min}} \right)^{\epsilon} \left( \frac{s_{ab}}{s_{min}} \right)^{\epsilon} \times \left\{ \frac{1}{\epsilon^2} \left( 1 - \frac{1}{2} \left( \frac{s_{ab}}{m_t^2} \right)^\epsilon \right) + \frac{1}{2\epsilon} \left( \frac{s_{ab}}{m_t^2} \right)^\epsilon - \frac{1}{2} \zeta(2) + \frac{m_t^2}{s_{ab}} \right\} ,
\]
(58)
where we have defined:

Finally, using Eqs. (59)-(62), we can derive the complete form of ̂σ_{soft}:

Finally, when \( a = t \) and \( b = \bar{t} \), i.e. when both quarks are massive, the corresponding integrated soft function \( S_{ti} \) is given by [10]:

where we have defined:

\[
\frac{m_i^2}{\sqrt{\lambda_{ti}}} \alpha_s N \frac{1}{\Gamma(1-\epsilon)} \left( \frac{4\pi \mu^2}{m_i} \right)^\epsilon \left\{ \frac{1}{2\epsilon^2} + \frac{1}{2\epsilon} \ln \left( \frac{m_i^2}{m_{\text{min}}^2} \right) \right\} \text{ (60)}
\]

Finally, using Eqs. (59)-(62), we can derive the complete form of ̂σ_{soft}:

\[
\hat{\sigma}^{h \to q\bar{q} \ell\ell\bar{\ell}}_{\text{soft}} = \frac{\alpha_s}{2\pi} \frac{1}{\Gamma(1-\epsilon)} \left( \frac{4\pi \mu^2}{m_i^2} \right)^\epsilon \int d(PS_4) \sum \left| A_{LO}^{h \to q\bar{q} \ell\ell\bar{\ell}} \right|^2 \left\{ \tilde{X}_2^s + \tilde{X}_1^s + N \tilde{C}_1^s + \tilde{C}_2^s \right\},
\]

(63)
where

\[
X_{s2}^s = \left(N - \frac{1}{N}\right),
\]

\[
X_{s1}^s = N \left[1 + 2 \ln \left(\frac{m_t^2}{s_{\min}}\right)\right] - \frac{1}{N} \left[\ln \left(\frac{s}{s_{\min}}\right) + \ln \left(\frac{m_t^2}{s_{\min}}\right) + 1 - \frac{s_{tt}}{(2m_t^2 + s_{tt})\beta_{tt}}\right],
\]

\[
\tilde{C}_1^s = 2 \ln^2 \left(\frac{m_t^2}{s_{\min}}\right) + \ln \left(\frac{m_t^2}{s_{\min}}\right) - \frac{1}{2} \ln^2 \left(\frac{s_{qt}}{m_t^2}\right) - \frac{1}{2} \ln^2 \left(\frac{s_{qt}}{m_t^2}\right) + \ln \left(\frac{s_{qt}s_{\tilde{q}t}}{m_t^2s_{\min}}\right)
\]

\[
- \zeta(2) + m_t^2 \left(\frac{1}{s_{qt}} + \frac{1}{s_{\tilde{q}t}}\right),
\]

\[
\tilde{C}_2^s = - \left[\frac{1}{2} \ln^2 \left(\frac{m_t^2}{s_{\min}}\right) + \ln \left(\frac{m_t^2}{s_{\min}}\right) \left(\ln \left(\frac{s}{s_{\min}}\right) + 1 - \frac{s_{tt}}{(2m_t^2 + s_{tt})\beta_{tt}}\right)\right]
\]

\[
\quad + \frac{1}{2} \ln^2 \left(\frac{s}{s_{\min}}\right) + \frac{m_t^2}{\beta_{tt}} (J_a + J_b) + \ln^2 \left(\frac{s_{qt}}{m_t^2}\right) - \ln^2 \left(\frac{s_{qt}}{m_t^2}\right) - \ln^2 \left(\frac{s_{\tilde{q}t}}{m_t^2}\right)
\]

\[
\quad + \ln^2 \left(\frac{s_{\tilde{q}t}}{m_t^2}\right) - 2 \ln \left(\frac{s_{qt}s_{\tilde{q}t}}{s_{\min}}\right) - 2m_t^2 \left(\frac{1}{s_{qt}} - \frac{1}{s_{\tilde{q}t}} + \frac{1}{s_{\tilde{q}t}}\right)\right].
\]

(64)

4.2.2 Collinear gluon emission

In the collinear limit when an external massless quark (i) and a hard gluon become collinear and cluster to form a new parton (i') (i + g → i', with collinear kinematics: \(p_i = z p_{i'}\) and \(k = (1 - z)p_{i'}\)), the color ordered amplitudes factorize and the amplitude squared for \(h \rightarrow q\bar{q}\tilde{t} + g\) can be written as:

\[
\sum |A_{\text{hist}}|^2 \sum |A_{\text{coll}}|^2 = \left(\frac{g_s^2 N}{2}\right) \sum |A_{\text{LO}}|^2 \left\{ f^q_{\tilde{t}g \rightarrow q} + f^q_{\tilde{t}g \rightarrow \tilde{q}} - \frac{1}{N^2} \left[ f_{\tilde{q}}^q_{\tilde{g} \rightarrow \tilde{q}} + f_{\tilde{g}}^q_{\tilde{g} \rightarrow \tilde{q}} - 2 \left( f_{\tilde{g}}^q_{g \rightarrow q} - f_{\tilde{q}}^q_{g \rightarrow \tilde{q}} - f_{\tilde{g}}^q_{g \rightarrow \tilde{q}} + f_{\tilde{q}}^q_{g \rightarrow \tilde{q}}\right)\right]\right\}.
\]

(65)

The collinear functions \(f^q_{\tilde{g} \rightarrow i'}\) contain the collinear singularity and are proportional to the Altarelli-Parisi splitting function for \(ig \rightarrow i'\) (see Eq. (11)), i.e.:

\[
f^q_{\tilde{g} \rightarrow i'} \equiv \frac{2}{s_{ig}} \left(\frac{1 + z^2}{1 - z} - \epsilon(1 - z)\right).\]

(66)

Using this definition, we can see that Eq. (15) is equivalent to Eq. (11), although \(q\) and \(\tilde{q}\), the massless quarks, are now considered as final state quarks. The reason why we use a more involved expression is because this allows us to match the collinear and soft regions of the gluon phase space in a very natural way, as will be explained in the following. In the same spirit, the lower index \(j\) of the collinear functions \(f^q_{\tilde{g} \rightarrow i'}\) keeps track of which color ordered amplitude a
given collinear pole comes from. Although seemingly useless at this stage, this will be crucial in deriving Eqs. (67) and (68), where the integration over the collinear region of the gluon phase space is performed in such a way to avoid to overlap with the soft gluon phase space integration in Eqs. (54) and (50). Finally, we note that there is no \( f_t^{ig\rightarrow t} \) or \( f_t^{tg\rightarrow t} \) in Eq. (65) since the gluon emission from a massive quark does not give origin to collinear singularities.

In the collinear limit, the \( h \rightarrow q\bar{q}t\bar{t} + g \) phase space also factorizes, in complete analogy to Eq. (12), provided the obvious changes between initial and final state partons are taken into account. Therefore, we can integrate out analytically the collinear gluon degrees of freedom and obtain the collinear part of the partonic cross section for \( h \rightarrow q\bar{q}t\bar{t} + g \) as:

\[
\hat{\sigma}_{\text{coll}}^{h \rightarrow q\bar{q}t\bar{t}} = \int d(P S_g) \sum |A_{LO}^{h \rightarrow q\bar{q}t\bar{t}}|^2 \left\{ C_{qt} + C_{\bar{q}t} - \frac{1}{N^2} \left[ C_{q\bar{t}} - 2 (C_{qt} - C_{\bar{q}t} - C_{q\bar{t}} + C_{\bar{q}t}) \right] \right\} ,
\]

(67)

where, for any pair of quarks \((i, j)\), the integrated collinear functions \( C_{ij} \) are defined as:

\[
C_{ij} = \left( \frac{g_s^2 N}{2} \right) \int d(P S_g)_{\text{coll}}(i, j, z) f_{j}^{ig\rightarrow i'}(z) = -\left( \frac{\alpha_s N}{2\pi} \right) \frac{1}{\Gamma(1-\epsilon)} \left( \frac{4\pi N^2}{s_{\text{min}}} \right)^{\epsilon} \frac{1}{\epsilon} I_{ig\rightarrow i'}(z_1, z_2) .
\]

(68)

The phase space of the collinear gluon can be written as:

\[
d(P S_g)_{\text{coll}}(i, j, z) = \frac{1}{16\pi^2} \frac{1}{\Gamma(1-\epsilon)} s_{ig}^{-\epsilon} d s_{ig}[z(1-z)]^{-\epsilon} d z (s_{\text{min}} - s_{ig}) ,
\]

(69)

and the integration boundaries on \( z \) are defined by the requirement that only one \( s_{ig} \) verifies the condition \( s_{ig} < s_{\text{min}} \). This is necessary in order to avoid overlapping with the region of phase space where the gluon is soft (see Eq. (52)), and it is easily translated into an upper bound on the \( z \) integration, thanks to the structure of Eqs. (53) and (67). In fact, each term in Eqs. (53) and (50) depends on only two invariants, \( s_{ig} \) and \( s_{jg} \), and each term in \( \hat{\sigma}_{\text{coll}}^{h \rightarrow q\bar{q}t\bar{t}} \) corresponds to an analogous term in \( \sigma_{\text{soft}}^{h \rightarrow q\bar{q}t\bar{t}} \) (except that \( C_{it} \) is missing since there is no collinear emission from \( t \) and \( \bar{t} \)). Therefore, for each \( C_{ij} \) we only need to require that when \( s_{ig} < s_{\text{min}} \):

\[
s_{jg} = (1-z)s_{ij}' > s_{\text{min}} \quad \rightarrow \quad z < 1 - s_{\text{min}}/s_{ij}' = 1 - z_2 .
\]

(70)

The lower bound on \( z \) is not constrained and the integration starts at \( z_1 = 0 \). For sake of simplicity, and since this does not give origin to ambiguities, in the following we will denote the \( s_{ij}' \) invariants in Eq. (70) by \( s_{ij} \). Finally, when the integration over the collinear gluon degrees of freedom is performed, one finds that the \( I_{ig\rightarrow i'}(z_1, z_2) \) functions in Eq. (68) are of the form [14]:

\[
I_{ig\rightarrow i'}(z_1, z_2) = \left[ \frac{z_2 - 1}{\epsilon} \right] - \frac{3}{4} + \left( \frac{\pi^2}{6} - \frac{7}{4} \right) \epsilon + O(\epsilon^2) .
\]

(71)
When \( i = q, \bar{q} \) and \( j = t, \bar{t} \), i.e. when one quark is massless and the other is massive, the integrated collinear functions \( C_{ij} \) are given by:

\[
C_{ij} = \left( \frac{\alpha_s N}{2\pi} \right) \frac{1}{\Gamma(1-\epsilon)} \frac{4\pi \mu^2}{s_{\text{min}}} \left\{ \left[ \ln \left( \frac{s_{ij}}{s_{\text{min}}} \right) - \frac{3}{4} \right] \frac{1}{\epsilon} + \frac{\pi^2}{6} - \frac{7}{4} + O(\epsilon) \right\},
\]

(72)

while when both \( i, j = q, \bar{q} \), i.e. when both quarks are massless,

\[
C_{q\bar{q}} = \left( \frac{\alpha_s N}{2\pi} \right) \frac{1}{\Gamma(1-\epsilon)} \frac{4\pi \mu^2}{s_{\text{min}}} \left\{ \left[ 2 \ln \left( \frac{s}{s_{\text{min}}} \right) - \frac{3}{2} \right] \frac{1}{\epsilon} + \ln^2 \left( \frac{s}{s_{\text{min}}} \right) \right\},
\]

(73)

Using these results, we can finally explicitly write the partonic cross section for collinear gluon radiation as follows:

\[
\hat{\sigma}_{\text{coll}}^{h \rightarrow q\bar{q}t\bar{t}g} = \left( \frac{\alpha_s}{2\pi} \right) \frac{1}{\Gamma(1-\epsilon)} \left( \frac{4\pi \mu^2}{m_t^2} \right) \int d(PS_4) \sum |A_{\text{LO}}^{h \rightarrow q\bar{q}t\bar{t}g}|^2 \left\{ \frac{X_{-1}}{\epsilon} + NC_1 + \frac{C_2}{N} \right\},
\]

(74)

where

\[
X_{-1} = N \left[ \frac{3}{2} - \ln \left( \frac{s_{\bar{q}t}}{s_{\text{min}}} \right) - \ln \left( \frac{s_{qt}}{s_{\text{min}}} \right) \right] + \frac{1}{N} \left[ -\frac{3}{2} + 2 \ln \left( \frac{s}{s_{\text{min}}} \right) - 2 \ln \left( \frac{s_{qt}s_{\bar{q}t}}{s_{\text{min}}} \right) \right],
\]

(75)

\[
C_1^c = -\ln \left( \frac{m_t^2}{s_{\text{min}}} \right) \left( \ln \left( \frac{s_{\bar{q}t}}{s_{\text{min}}} \right) + \ln \left( \frac{s_{qt}}{s_{\text{min}}} \right) - \frac{3}{2} \right) - \frac{1}{2} \ln^2 \left( \frac{s_{\bar{q}t}}{s_{\text{min}}} \right) + \frac{1}{2} \ln^2 \left( \frac{s_{qt}}{s_{\text{min}}} \right) + \frac{7}{2} - \frac{\pi^2}{3},
\]

\[
C_2^c = \ln^2 \left( \frac{s}{s_{\text{min}}} \right) + \ln^2 \left( \frac{s_{\bar{q}t}}{s_{\text{min}}} \right) + \ln^2 \left( \frac{s_{qt}}{s_{\text{min}}} \right) - \ln^2 \left( \frac{s_{\bar{q}t}}{s_{\text{min}}} \right) - \ln^2 \left( \frac{s_{qt}}{s_{\text{min}}} \right) + \ln \left( \frac{m_t^2}{s_{\text{min}}} \right) \left[ -\frac{3}{2} + 2 \ln \left( \frac{s}{s_{\text{min}}} \right) - 2 \ln \left( \frac{s_{qt}s_{\bar{q}t}}{s_{\text{min}}} \right) \right] + \frac{\pi^2}{3} - \frac{7}{2}.
\]

\[\]

4.2.3 IR-singular gluon emission: complete result for \( \hat{\sigma}_{\text{IR}} \)

As already described in the beginning of Sec. 4.2.2, the partonic cross section for the IR-singular real gluon radiation for the process \( q\bar{q} \rightarrow t\bar{t}h \) using the one-cutoff PSS method is given by

\[
\hat{\sigma}_{\text{IR}} = \hat{\sigma}_{\text{IR}}^{\text{coll}} + \hat{\sigma}_{\text{IR}}^{\text{soft}}
\]

\[
= \left[ \hat{\sigma}_{\text{IR}}^{\text{coll}} + \hat{\sigma}_{\text{IR}}^{\text{soft}} \right]_{\text{crossed}} + \hat{\sigma}_{\text{crossing}}.
\]

(76)
Note that crossing $\hat{\sigma}^{h\rightarrow q\bar{q}tg}$ and $\hat{\sigma}^{h\rightarrow q\bar{q}tg}$ only implies the interchange of the momenta of the quark and antiquark, since particle and antiparticle interchange under crossing. In the case of soft gluon emission this can be easily verified by comparing Eq. (29) with Eq. (53), after flipping helicities and momenta of the crossed particles. For collinear gluon emission, the crossing is complicated by the difference between initial and final state collinear radiation. Using $\hat{\sigma}^{h\rightarrow q\bar{q}tg}$ in Eqs. (13) and (14), $\hat{\sigma}_{ir}$ can be explicitly written as:

$$\hat{\sigma}_{ir} = \left(\frac{\alpha_s}{2\pi}\right) N_f \int d(PS_3) \sum |A_{LO}|^2 \left\{ \frac{X^{ir}}{\epsilon^2} + \frac{X^{-1}}{\epsilon} + C_1 N + C_2 \frac{1}{N} \right\}, \quad (77)$$

where

$$X^{ir} = -X^{-1}, \quad X^{-1} = -X^{ir}.$$

$$C_1^{ir} = \ln \left(\frac{m_t^2}{s_{min}}\right) \left[ -2 \ln \left(\frac{s_{\hat{q}}}{m_t^2}\right) - 2 \ln \left(\frac{s_{\hat{q}}}{m_t^2}\right) + \frac{7}{2} - \ln \left(\frac{m_t^2}{s_{min}}\right) \right]$$

$$+ \ln \left(\frac{s_{\hat{q}}}{m_t^2}\right) + \ln \left(\frac{s_{\hat{q}}}{m_t^2}\right) - \ln^2 \left(\frac{s_{\hat{q}}}{m_t^2}\right) - \ln^2 \left(\frac{s_{\hat{q}}}{m_t^2}\right)$$

$$+ \frac{7}{2} - \frac{\pi^2}{2} - \zeta(2) + m_t^2 \left(\frac{1}{s_{\hat{q}}} - \frac{1}{s_{\hat{q}}}\right) ,$$

$$C_2^{ir} = \ln \left(\frac{m_t^2}{s_{min}}\right) \left[ 2 \ln \left(\frac{s}{m_t^2}\right) + 4 \ln \left(\frac{s_{\hat{q}}}{s_{\hat{q}}}\right) - \frac{5}{2} + \ln \left(\frac{m_t^2}{s_{min}}\right) + \frac{s_{\bar{t}}}{(2m_t^2 + s_{\bar{t}})\beta_{\bar{t}}}, \right]$$

$$+ \frac{1}{2} \ln^2 \left(\frac{s}{m_t^2}\right) - 2 \ln^2 \left(\frac{s_{\hat{q}}}{m_t^2}\right) + 2 \ln^2 \left(\frac{s_{\hat{q}}}{m_t^2}\right) + 2 \ln^2 \left(\frac{s_{\hat{q}}}{m_t^2}\right)$$

$$- 2 \ln \left(\frac{s_{\hat{q}}}{s_{\hat{q}}\bar{t}}\right) - 2 m_t^2 \left(\frac{1}{s_{\hat{q}}} - \frac{1}{s_{\hat{q}}} - \frac{1}{s_{\bar{t}}} + \frac{1}{s_{\bar{t}}}\right)$$

$$+ \frac{\pi^2}{2} - \frac{7}{2} - \frac{m_t^2}{\sqrt{\lambda_{\bar{t}}}} (J_a + J_b) .$$

while $N_f$ is defined in Eq. (13), and $A_{LO}$ is the tree-level amplitude for $q\bar{q} \rightarrow t\bar{t}h$ in $d = 4$ dimensions.

As described in detail in Ref. [15], $\hat{\sigma}_{crossing}$ is given by

$$\hat{\sigma}_{crossing} = \alpha_s \int_0^1 dz \hat{\sigma}_{LO}^{q\bar{q}} (X_{q\rightarrow q}(z) + X_{q\rightarrow q}(z)), \quad (79)$$

where $X_{q\rightarrow q}(z) (X_{q\rightarrow q}(z))$ is the unrenormalized crossing function of Ref. [15], which accounts for the difference between collinear gluon radiation off an initial or a final state quark (antiquark):

$$X_{q\rightarrow q}(z) = - \frac{C_F}{2\pi} \left(\frac{4\pi \mu^2}{s_{min}}\right)^\epsilon \frac{1}{\Gamma(1 - \epsilon)} \left(\frac{1}{\epsilon}\right) \times$$

$$\left\{ \left[ 3 - \epsilon \left(\frac{\pi^2}{3} - \frac{7}{2}\right) \right] \delta(1 - z) + \left[ \frac{1 + z^2}{(1 - z)^{1+\epsilon}} + \epsilon (1 - z)^{1-\epsilon} \right] \right\}. \quad (80)$$
5 Total cross section for $p\bar{p} \to t\bar{t}h$ and mass factorization

As described in Sec. 2, the observable total cross section at NLO is obtained by convoluting the parton cross section with the NLO quark distribution functions $F^p_{q}(x, \mu)$, thereby absorbing the remaining initial-state singularities of $\delta \sigma^q_{NLO}$ into the quark distribution functions. This can be understood as follows. First the parton cross section is convoluted with the bare quark distribution functions $F^p_{q}(x)$ and subsequently $F^p_{q}(x, \mu)$ is replaced by the renormalized quark distribution functions $\hat{F}^p_{q}(x, \mu)$ defined in some subtraction scheme. Using the $\overline{MS}$ scheme, the scale-dependent NLO quark distribution functions are given in terms of $F^p_{q}(x, \mu)$ and the QCD NLO parton distribution function counterterms $[13, 15]$ as follows:

\[
\begin{align*}
\text{two-cutoff PSS method} \\
F^p_{q}(x, \mu) &= F^p_{q}(x) \left[ 1 - \frac{\alpha_s}{2\pi} \frac{\Gamma(1-\epsilon)}{(1-\epsilon)} \left( \frac{4\pi}{\epsilon} \right) \frac{1}{\epsilon} C_F \left( 2 \ln(\delta_s) + \frac{3}{2} \right) \right] \\
&\quad + \left[ \frac{\alpha_s}{2\pi} \frac{\Gamma(1-\epsilon)}{(1-\epsilon)} \right] \int_x^{1-\delta_s} \frac{dz}{z} \left( -\frac{1}{\epsilon} \right) P_{qq}(z) F^p_{j}(\frac{x}{z}) \, ,
\end{align*}
\]

\[
\begin{align*}
\text{one-cutoff PSS method} \\
F^p_{q}(x, \mu) &= F^p_{q}(x) \left[ 1 - \frac{\alpha_s}{2\pi} \frac{(4\pi)_s^{\epsilon}}{\epsilon} \left( \frac{1}{\epsilon} \right) C_F \frac{3}{2} \right] \\
&\quad + \left[ \frac{\alpha_s}{2\pi} \frac{(4\pi)^\epsilon}{\epsilon} \right] \int_x^1 \frac{dz}{z} \left( -\frac{1}{\epsilon} \right) C_F \frac{1 + z^2}{(1-z)_+} F^p_{j}(\frac{x}{z}) \, ,
\end{align*}
\]

where the $O(\alpha_s)$ terms in the previous equations are calculated from the $O(\alpha_s)$ corrections to the $q \to qg$ splitting, in the PSS formalism, and $P_{qq}(z)$ is the Altarelli-Parisi splitting function of Eq. (41). Note that, again, we choose the factorization and renormalization scales to be equal. Therefore there is no explicit factorization scale dependence in Eqs. (81) and (82), and the only $\mu$-dependence in $F^p_{q}(x, \mu)$ comes from $\alpha_s(\mu)$. When using the two-cutoff method and convoluting the parton cross section with the renormalized quark distribution function of Eq. (81), the IR singular counterterm of Eq. (81) exactly cancels the remaining IR poles of $\hat{\sigma}^{qg} + \hat{\sigma}^{soft}$ and $\hat{\sigma}^{hard/coll}$. In case of the one-cutoff PSS method, the IR singular counterterm of Eq. (82) exactly cancels the IR poles of $\hat{\sigma}^{crossing}$. Finally, the complete $O(\alpha_s^2)$ inclusive total cross section for $p\bar{p} \to t\bar{t}h$ in the $\overline{MS}$ factorization scheme can be written as follows:

\[
\begin{align*}
\sigma_{NLO} &= \sum_{qq} \int dx_1 dx_2 F^p_{q}(x_1, \mu) F^p_{\bar{q}}(x_2, \mu) \left[ \hat{\sigma}^{qq}_{NLO}(x_1, x_2, \mu) + \hat{\sigma}^{qg}(x_1, x_2, \mu) + \hat{\sigma}^{soft}(x_1, x_2, \mu) \right] \\
&\quad + \frac{\alpha_s}{2\pi} C_F \sum_{qq} \int dx_1 dx_2 \left\{ \int_{x_1}^{1-\delta_s} \frac{dz}{z} \left[ F^p_{q}(\frac{x_1}{z}, \mu) F^p_{\bar{q}}(x_2, \mu) + F^p_{\bar{q}}(x_2, \mu) F^p_{q}(\frac{x_1}{z}, \mu) \right] \right\} \, .
\end{align*}
\]
Figure 7: Dependence of $\sigma_{NLO}(p\bar{p} \to t\bar{t}h)$ on the arbitrary cutoff of the one-cutoff PSS method, $s_{\rm min}$, at $\sqrt{s_H} = 2$ TeV, for $M_h = 120$ GeV, and $\mu = m_t$. The upper plot shows the cancellation of the $s_{\rm min}$ dependence between $\sigma_{ir}$, $\sigma_{\text{crossing}}$, and $\sigma_{\text{hard}}$. The lower plot shows, on an enlarged scale, the dependence of $\sigma_{NLO}$ on $s_{\rm min}$, with the corresponding statistical errors.

\[
\times \hat{\sigma}_{LO}^{qq}(x_1, x_2, \mu) \left[ \frac{1 + z^2}{1 - z} \ln \left( \frac{s}{\mu^2} \frac{(1 - z)^2 \delta_c}{2} \right) + 1 - z \right] + (1 \leftrightarrow 2) \right) \\
+ \sum_{q\bar{q}} \int dx_1 dx_2 F_p^q(x_1, \mu) F_{\bar{q}}^{\bar{p}}(x_2, \mu) \hat{\sigma}_{\text{hard/soft}}(x_1, x_2, \mu) ,
\]

with

$\hat{\sigma}'_{\text{soft}} = \hat{\sigma}_{\text{soft}} + \frac{\alpha_s}{2\pi} \frac{\Gamma(1 - \epsilon)}{\Gamma(1 - 2\epsilon)} \frac{1}{(4\pi)^\epsilon} \left( \frac{1}{\epsilon} \right) C_F \left[ 4 \ln(\delta_s) + 3 \right] , \quad (84)$

one-cutoff PSS method

\[
\sigma_{NLO} = \sum_{q\bar{q}} \int dx_1 dx_2 F_p^q(x_1, \mu) F_{\bar{q}}^{\bar{p}}(x_2, \mu) \left\{ \hat{\sigma}_{LO}^{qq}(x_1, x_2, \mu) + \hat{\sigma}_{\text{virt}}^{qq}(x_1, x_2, \mu) \right\} \\
+ \frac{\alpha_s}{2\pi} \frac{\Gamma(1 - \epsilon)}{\Gamma(1 - 2\epsilon)} \frac{1}{(4\pi)^\epsilon} \left( \frac{1}{\epsilon} \right) C_F \left[ 4 \ln(\delta_s) + 3 \right] , \quad (85)
\]

\[
\times \hat{\sigma}_{LO}^{qq}(x_1, x_2, \mu) \left[ \frac{1 + z^2}{(1 - z)^+} \ln \left( \frac{s}{\mu^2} \frac{s_{\text{min}}}{s} \right) + 1 - z + (1 + z^2) \left( \frac{\ln(1 - z)}{1 - z} \right)_+ \right] \\
\]
\[ + (1 \leftrightarrow 2) \right) + \sum_{q \bar{q}} \int dx_1 dx_2 F_q^p(x_1, \mu) F_{\bar{q}}^p(x_2, \mu) \hat{\sigma}_{hard}(x_1, x_2, \mu). \]

We note that \( \sigma_{NLO} \) is finite, since, after mass factorization, both soft and collinear singularities have been canceled between \( \hat{\sigma}_{virt}^{q\bar{q}} + \hat{\sigma}_{soft}' \) and \( \hat{\sigma}_{hard/coll} \) in the two-cutoff PSS method, and between \( \hat{\sigma}_{virt}^{q\bar{q}} \) and \( \hat{\sigma}_{c}^{\alpha} \) in the one-cutoff PSS method. The last terms respectively describe the finite real gluon emission of Eq. (27) and Eq. (45). Note that the second term in Eqs. (83) and (85), which is proportional to \( \ln \left( \frac{s_{\mu^2}}{\mu^2} \right) \), corresponds exactly to the second and third terms of Eq. (7), as predicted by renormalization group arguments. Before we discuss in detail the

Figure 8: Dependence of \( \sigma_{NLO}(p\bar{p} \rightarrow t\bar{t}h) \) on the soft cutoff \( \delta_s \) of the two-cutoff PSS method, at \( \sqrt{s_h} = 2 \) TeV, for \( M_h = 120 \) GeV, \( \mu = m_t \), and \( \delta_c = 10^{-4} \). The upper plot shows the cancellation of the \( \delta_s \)-dependence between \( \sigma_{soft} + \sigma_{hard/coll} \) and \( \sigma_{hard/non-coll} \). The lower plot shows, on an enlarged scale, the dependence of \( \sigma_{NLO} \) on \( \delta_s \) with the corresponding statistical errors.

numerical results for the NLO total cross section for \( p\bar{p} \rightarrow t\bar{t}h \) we first demonstrate that \( \sigma_{NLO} \) does not depend on the arbitrary cutoffs of the PSS method, i.e. on \( s_{min} \) when we use the one-cutoff method, and on the soft and hard/collinear cutoffs \( \delta_s \) and \( \delta_c \) when we use the two-cutoff method. We note that the cancellation of the cutoff dependence at the level of the total NLO cross section is a very delicate issue, since it involves both analytical and numerical contributions. It is crucial to study the behavior of \( \sigma_{NLO} \) in a region where the cutoff(s) are small enough to justify the approximations used in the analytical calculation of the IR-divergent part of \( \hat{\sigma}_{real}^{q\bar{q}} \), but not so small to give origin to numerical instabilities.
Fig. 7 is about the one-cutoff PSS method and shows the dependence of $\sigma_{NLO}$ on $s_{min}$. In the upper window, we illustrate the cancellation of the $s_{min}$ dependence between $\sigma_{ir}$, $\sigma_{crossing}$, and $\sigma_{hard}$, while in the lower window, we show, on a larger scale, the behavior of $\sigma_{NLO}$ including the statistical errors from the Monte-Carlo integration. We note that $\sigma_{NLO}$ also includes the Born cross section and the virtual contribution to the NLO cross section, which are both $s_{min}$-independent, and are therefore not shown explicitly in the upper part of Fig. 7. Clearly a plateau is reached in the region $0.1 \text{ GeV}^2 < s_{min} < 100 \text{ GeV}^2$.

Figs. 8 and 9 are about the two-cutoff PSS method. In Fig. 8, we show the dependence of $\sigma_{NLO}$ on the soft cutoff, $\delta_s$, for a fixed value of the hard/collinear cutoff, $\delta_c = 10^{-4}$. In Fig. 9, we show the dependence of $\sigma_{NLO}$ on the hard/collinear cutoff, $\delta_c$, for a fixed value of the soft cutoff, $\delta_s = 5 \times 10^{-4}$. In the upper window of Fig. 8(9), we illustrate the cancellation of the $\delta_s(\delta_c)$ dependence between $\sigma_{soft} + \sigma_{hard/coll}$ and $\sigma_{hard/non-coll}$. The lower plot shows, on an enlarged scale, the dependence of $\sigma_{NLO}$ on $\delta_c$ with the corresponding statistical errors.

Figure 9: Dependence of $\sigma_{NLO}(p\bar{p} \rightarrow t\bar{t}h)$ on the collinear cutoff $\delta_c$ of the two-cutoff PSS method, at $\sqrt{s_H} = 2 \text{ TeV}$, for $M_h = 120 \text{ GeV}$, $\mu = m_t$, and $\delta_s = 5 \times 10^{-4}$. The upper plot shows the cancellation of the $\delta_c$-dependence between $\sigma_{soft} + \sigma_{hard/coll}$ and $\sigma_{hard/non-coll}$. The lower plot shows, on an enlarged scale, the dependence of $\sigma_{NLO}$ on $\delta_c$ with the corresponding statistical errors.

Figs. 8 and 9 are about the two-cutoff PSS method. In Fig. 8, we show the dependence of $\sigma_{NLO}$ on the soft cutoff, $\delta_s$, for a fixed value of the hard/collinear cutoff, $\delta_c = 10^{-4}$. In Fig. 9, we show the dependence of $\sigma_{NLO}$ on the hard/collinear cutoff, $\delta_c$, for a fixed value of the soft cutoff, $\delta_s = 5 \times 10^{-4}$. In the upper window of Fig. 8(9), we illustrate the cancellation of the $\delta_s(\delta_c)$ dependence between $\sigma_{soft} + \sigma_{hard/coll}$ and $\sigma_{hard/non-coll}$, while in the lower window, we show, on a larger scale, $\sigma_{NLO}$ with the statistical errors from the Monte-Carlo integration. As before, $\sigma_{NLO}$ also includes the contribution from the Born and the virtual cross sections, which are both cutoff-independent and are not shown explicitly in the upper parts of Figs. 8. For $\delta_s$ in the range $10^{-4} - 2.5 \times 10^{-3}$ and $\delta_c$ in the range $10^{-5} - 10^{-3}$, a clear plateau is reached and the NLO total cross section is independent of the technical cutoffs of the two-cutoff PSS method. All the results presented in the following are obtained using the two-cutoff PSS method with
\( \delta_s \) and \( \delta_c \) in the range \( 10^{-4} - 10^{-3} \). We have confirmed them using the one-cutoff PSS method with \( 1 \leq s_{\text{min}} \leq 10 \).

6 Numerical results

In the following we discuss in detail our results for the NLO inclusive total cross section for \( \bar{p}p \rightarrow t\bar{t}h \), \( \sigma_{\text{NLO}}(\bar{p}p \rightarrow t\bar{t}h) \), as introduced in Sect. 2 and explicitly given by Eqs. (83) and (85). Our numerical results are found using CTEQ4M parton distribution functions [33] and the 2-loop evolution of \( \alpha_s(\mu) \) for the calculation of the NLO cross section, and CTEQ4L parton distribution functions and the 1-loop evolution of \( \alpha_s(\mu) \) for the calculation of the lowest order cross section, unless stated otherwise. The top-quark mass is taken to be \( m_t = 174 \text{ GeV} \) and \( \alpha_{\text{NLO}}(M_Z) = 0.116 \).

![Figure 10](image)

Figure 10: Dependence of \( \sigma_{\text{LO, NLO}}(\bar{p}p \rightarrow t\bar{t}h) \) on the renormalization/factorization scale \( \mu \), at \( \sqrt{s_H} = 2 \text{ TeV} \), for \( M_h = 120 \text{ GeV} \).

First of all, in Fig. 10 we show how at NLO the dependence on the arbitrary renormalization/factorization scale \( \mu \) is significantly reduced. We use \( M_h = 120 \text{ GeV} \) for illustration purposes. We note that only for scales \( \mu \) of the order of \( 2m_t + M_h \) or bigger is the NLO result greater than the lowest order result at \( \sqrt{s_H} = 2 \text{ TeV} \).

Fig. 11 shows both the LO and the NLO total cross section for \( \bar{p}p \rightarrow t\bar{t}h \) as a function of \( M_h \), at \( \sqrt{s_H} = 2 \text{ TeV} \), for two values of the renormalization/factorization scale, \( \mu = m_t \) and \( \mu = 2m_t \). Over the entire range of \( M_h \) accessible at the Tevatron, the NLO corrections decrease the rate
Figure 11: $\sigma_{NLO}$ and $\sigma_{LO}$ for $p\bar{p} \rightarrow t\bar{t}h$ as functions of $M_h$, at $\sqrt{s} = 2$ TeV, for $\mu = m_t$ and $\mu = 2m_t$.

Figure 12: K-factor for $p\bar{p} \rightarrow t\bar{t}h$ as a function of $M_h$, at $\sqrt{s} = 2$ TeV, for $\mu = m_t$ and $\mu = 2m_t$. 
for renormalization/factorization scales $\mu < 2m_t + M_h$. The reduction is much less dramatic at $\mu = 2m_t$ than at $\mu = m_t$, as can be seen from both Fig. 10 and Fig. 11. An illustrative sample of results is also given in Table 1. The error we quote on our values is the statistical error of the numerical integration involved in evaluating the total cross section. We estimate the remaining theoretical uncertainty on the NLO results to be of the order of 12%. This is mainly due to: the left over $\mu$-dependence (about 8%), the dependence on the PDFs (about 6%), and the error on $m_t$ (about 7%) which particularly plays a role in the Yukawa coupling.

The corresponding K-factor, i.e. the ratio of the NLO cross section to the LO one,

$$K = \frac{\sigma_{NLO}}{\sigma_{LO}},$$

is shown in Fig. 12. For scales $\mu$ between $\mu = m_t$ and $\mu = 2m_t$, the K-factor varies roughly between $K = 0.70$ and $K = 0.95$, when $M_h$ varies in the range between 100 and 200 GeV. For scales of the order of $\mu = 2m_t + M_h$ the K-factor is of order one and becomes larger than one for higher scales. Given the strong scale dependence of the LO cross section, the K-factor also shows a significant $\mu$-dependence and therefore is an equally unreliable prediction. Moreover it is important to remember that the K-factor depends on how the LO cross section is calculated. We choose to calculate the LO cross section using both LO $\alpha_s(\mu)$ and LO PDFs, denoted by $\sigma_{LO}$ in Table 1. An equally valid approach could be to evaluate the LO cross section using NLO $\alpha_s(\mu)$ and NLO PDFs, denoted by $\bar{\sigma}_{LO}$ in Table 1, in which case the K-factor would just represent the impact of the $O(\alpha_s)$ corrections that do not originate from the running

Table 1: Values of both $\sigma_{LO}$ (calculated with LO $\alpha_s(\mu)$ and LO PDFs), $\bar{\sigma}_{LO}$ (calculated with NLO $\alpha_s(\mu)$ and NLO PDFs), and $\sigma_{NLO}$ for different values of $M_h$ and for different renormalization/factorization scales $\mu$.

| $M_h$ (GeV) | $\mu$ | $\sigma_{LO}$ (fb) | $\bar{\sigma}_{LO}$ (fb) | $\sigma_{NLO}$ (fb) |
|------------|-------|---------------------|--------------------------|---------------------|
| 120        | $m_t$ | $6.8662 \pm 0.0013$ | $5.2843 \pm 0.0008$     | $4.863 \pm 0.029$  |
|            | $m_t + M_h/2$ | $5.9085 \pm 0.0011$ | $4.5846 \pm 0.0007$     | $4.847 \pm 0.024$  |
|            | $2m_t$ | $4.8789 \pm 0.0009$ | $3.8252 \pm 0.0006$     | $4.691 \pm 0.020$  |
|            | $2m_t + M_h$ | $4.2548 \pm 0.0008$ | $3.3600 \pm 0.0005$     | $4.511 \pm 0.017$  |
| 150        | $m_t$ | $3.4040 \pm 0.0006$ | $2.5811 \pm 0.0005$     | $2.355 \pm 0.013$  |
|            | $m_t + M_h/2$ | $2.8289 \pm 0.0005$ | $2.1668 \pm 0.0004$     | $2.315 \pm 0.011$  |
|            | $2m_t$ | $2.4007 \pm 0.0004$ | $1.8553 \pm 0.0004$     | $2.253 \pm 0.010$  |
|            | $2m_t + M_h$ | $2.0282 \pm 0.0004$ | $1.5813 \pm 0.0003$     | $2.147 \pm 0.008$  |
| 180        | $m_t$ | $1.7605 \pm 0.0003$ | $1.3153 \pm 0.0002$     | $1.160 \pm 0.007$  |
|            | $m_t + M_h/2$ | $1.4142 \pm 0.0003$ | $1.0693 \pm 0.0002$     | $1.158 \pm 0.005$  |
|            | $2m_t$ | $1.2326 \pm 0.0002$ | $0.9390 \pm 0.0001$     | $1.132 \pm 0.004$  |
|            | $2m_t + M_h$ | $1.0096 \pm 0.0002$ | $0.7773 \pm 0.0001$     | $1.069 \pm 0.004$  |
of $\alpha_s(\mu)$ and the PDFs. Since $\sigma_{LO} > \bar{\sigma}_{LO}$, the K-factor obtained using $\sigma_{LO}$ is smaller than the one obtained using $\bar{\sigma}_{LO}$, and it is important to match the right K-factor to the right $\sigma_{LO}$ or $\bar{\sigma}_{LO}$. Therefore we would like to stress once more that we only discuss the K-factor as a qualitative indication of the impact of $O(\alpha_s)$ QCD corrections, for different processes or when using different approaches. The physical meaningful quantity is the NLO cross section, not the K-factor.

For comparison, we have estimated the K-factor also in the EHA \cite{9}, and we obtain $K \approx 0.6 - 0.7$, for Higgs boson masses up to 150 GeV and renormalization/factorization scales in the range between $\mu = m_t$ and $\mu = 2m_t + M_h$. As anticipated, we do not expect the EHA to give a quantitatively good approximation of the full $p\bar{p} \to t\bar{t}h$ calculation at $O(\alpha_s)$, since at $\sqrt{s_H} = 2$ TeV and for a SM Higgs boson above the experimental bound, we cannot work in the limit $M_h, m_t/\sqrt{s} \ll 1$ or $M_h/m_t \ll 1$. Still the EHA gives a remarkably good qualitative indication of the fact that the first order QCD corrections may lower the LO total cross section.

It is interesting to compare our NLO result for $p\bar{p} \to t\bar{t}h$ with the NLO result for $p\bar{p} \to t\bar{t}$. Since the Higgs boson is colorless, one would naively expect the QCD corrections to both processes to be of roughly the same size. Defining the NLO cross section using the NLO evolution of $\alpha_s(\mu)$ and the NLO CTEQ4M PDFs, and the LO cross section using the LO evolution of $\alpha_s(\mu)$ and the LO CTEQ4L PDFs, the K-factor for $t\bar{t}$ production at $\sqrt{s_H} = 2$ TeV, with $\mu = m_t$ and $m_t = 174$ GeV, is:

$$K(p\bar{p} \to t\bar{t})_{q\bar{q}} = 0.98,$$
$$K(p\bar{p} \to t\bar{t})_{tot} = 1.05,$$  \hspace{1cm} (87)

where the $q\bar{q}$ label indicates that only the $q\bar{q}$ initial state is included. The size of the QCD corrections to $p\bar{p} \to t\bar{t}$ is thus similar in magnitude to the result obtained in Fig. 12, taking into account that $p\bar{p} \to t\bar{t}h$ is completely dominated by the $q\bar{q}$ channel. Of course, we do not expect a better agreement, since in $p\bar{p} \to t\bar{t}h$ an additional heavy particle is produced, and new contributions to the virtual corrections arise. Moreover, taking the EHA as an indication, one could naively expect that the radiation of a Higgs boson introduces an additional negative contribution. We also observe that, if we now use as LO cross section the one obtained using NLO $\alpha_s(\mu)$ and NLO CTEQ4M PDFs, the two K-factors in Eq. (87) increase, according to the comment we made above, and become:

$$K(p\bar{p} \to t\bar{t})_{q\bar{q}} = 1.18,$$
$$K(p\bar{p} \to t\bar{t})_{tot} = 1.24,$$  \hspace{1cm} (88)

in agreement with the literature \cite{34}. Moreover, since the NLO cross section for $p\bar{p} \to t\bar{t}$ is further increased by the resummation of the leading and next-to-leading logarithms arising \footnote{We have compared our results with Fig. 9 of Ref. \cite{34}, and we see very good agreement with the LO and the NLO curves, using $m_t = 175$ GeV and $\sqrt{s_H} = 1.8$ TeV.}
from the threshold region dynamics, the total K-factor for \( p\bar{p} \to t\bar{t} \) can be as high as 1.33 for \( \mu = m_t \). With this respect, we also note that, contrary to \( p\bar{p} \to t\bar{t} \), in the threshold region for \( p\bar{p} \to t\bar{t}h \) there are large negative contributions, mainly from soft gluon radiation, which are largely compensated by large positive contributions from hard gluon radiation at larger \( \sqrt{s} \). In the threshold region the Coulomb term, coming from the exchange of virtual gluons between the \( t/\bar{t} \) external legs, is important and contributes to decrease the NLO cross section, although it is moderated by the behavior of the three-body phase space. In the strict threshold limit, the Coulomb contribution to \( p\bar{p} \to t\bar{t}h \) goes to zero, while for \( t\bar{t} \) production it is constant and dominates the NLO cross section.

### 7 Conclusion

The NLO inclusive total cross section for the Standard Model process \( p\bar{p} \to t\bar{t}h \) at \( \sqrt{s_H} = 2 \) TeV shows a significantly reduced scale dependence as compared to the Born result and leads to increased confidence in predictions based on these results. The NLO QCD corrections slightly decrease or increase the Born level cross section depending on the renormalization/factorization scales used. The NLO inclusive total cross section for Higgs boson masses in the range accessible at the Tevatron, \( 120 < M_h < 180 \) GeV, is of the order of \( 1 - 5 \) fb.

The contributions to the NLO cross section resulting from real gluon emission have been calculated in two variations of the phase space slicing method, involving one or two arbitrary numerical cutoff parameters, respectively. This is the first application of the one-cutoff phase space slicing approach, ("\( s_{\text{min}} \)"), to a cross section involving more than one massive particle in the final state. The correspondence between the two phase space slicing approaches is made explicit. The virtual contributions to the NLO cross section require the calculation of both box and pentagon diagrams involving several massive particles and explicit results for the integrals have been presented in the appendices. These techniques can now be applied to other similar processes.

### Acknowledgments

We are particularly thankful to Z. Bern and F. Paige for valuable discussions and encouragement. We would like to thank W. Giele, S. Keller, and W. Kilgore for very useful suggestions and insights. We are grateful to the authors of Ref. [18] for detailed comparisons of results prior to publication. The work of L.R. (S.D.) is supported in part by the U.S. Department of Energy under grant DE-FG02-97ER41022 (DE-AC02-76CH00016). The work of D.W. is supported by the U.S. Department of Energy under grant DE-FG02-91ER40685.
A Pentagon scalar integrals

In this appendix we review the details of the calculation of the pentagon scalar integrals that appear in the calculation of diagrams $P_1$ and $P_2$ illustrated in Fig. 5. Using the momentum flow and the notation shown in Fig. 5, the pentagon scalar integral originating from diagram $P_1 (E_0p_1)$ can be written as:

$$E_0p_1 = \mu^{d-4} \int \frac{1}{(2\pi)^d N_1N_2N_3N_4N_5},$$  \hspace{1cm} (89)

where

$$N_1 = k^2, \hspace{1cm} (90)$$  
$$N_2 = (k + q_1)^2,$$  
$$N_3 = (k + q_1 + q_2)^2,$$  
$$N_4 = (k + q_1 + q_2 - p'_t)^2 - m_t^2,$$  
$$N_5 = (k + q_1 + q_2 - p'_t - p_h)^2 - m_t^2.$$

We note that we included a factor $\mu^{d-4}$ in the definition of the $d$-dimensional scalar integrals in order to have them in the most convenient form for the calculation of the virtual amplitude squared. The pentagon scalar integral originating from diagram $P_2, E_0p_2$, can be obtained from Eqs.(89) and (90) by exchanging $q_1 \leftrightarrow q_2$. Therefore in the following we limit our discussion to $E_0p_1$, the generalization to $E_0p_2$ being straightforward.

We calculate these integrals following the method introduced by the authors of Ref. [11]. To make contact with their notation, we denote by $k_i$ the external momenta (such that $k_i^2 = m_i^2$), by $M_i$ the internal masses, by $p_i$ the sum of the first $i$ external momenta, $p_i^\mu = \sum_{j=1}^{i} k_j^\mu$, by $p_{ij}$ the difference $p_{ij}^\mu = p_{i-1}^\mu - p_{j-1}^\mu = k_i^\mu + k_{i+1}^\mu + \cdots + k_{j-1}^\mu$ (for $i < j$), and finally by $s_{ij} = (k_i + k_j)^2$.

The topology of the generic pentagon scalar integral is illustrated in Fig. 13, which can be specified to our case by identifying:

$$k_1 \rightarrow -q_1 \text{ (incoming $q$)}$$  
$$k_2 \rightarrow -q_2 \text{ (incoming $\bar{q}$)}$$  
$$k_3 \rightarrow p'_t \text{ (outgoing $\bar{t}$)}$$  
$$k_4 \rightarrow p_h \text{ (outgoing $h$)}$$  
$$k_5 \rightarrow p_t \text{ (outgoing $t$)}.$$  \hspace{1cm} (91)

Using the standard Feynman parameterization technique, the pentagon integral in Eq.(89) can be written as:

$$E_0p_1 = -\frac{i}{16\pi^2} (4\pi \mu^2)^{\epsilon} \Gamma(3 + \epsilon) \int_{0}^{1} \frac{\prod_{i=1}^{5} da_i \delta(1 - \sum_{i=1}^{5} a_i)}{[D_{p_1}(a_i)]^{3+\epsilon}},$$  \hspace{1cm} (92)
where the denominator $D_{p1}(a_i)$ is:

$$D_{p1}(a_i) = \sum_{i,j=1}^{5} S_{ij} a_i a_j - i\eta \ , \quad (93)$$

and the symmetric matrix $S_{ij}$ is given by:

$$S_{ij} = \frac{1}{2}(M_i^2 + M_j^2 - p^2_{ij}) \ . \quad (94)$$

For our particular process, the matrix $S_{ij}$ has the following explicit form:

$$S = \frac{1}{2} \begin{pmatrix}
0 & 0 & -\tilde{s}_{12} & (m_i^2 - \tilde{s}_{45}) & 0 \\
0 & 0 & 0 & (m_i^2 - \tilde{s}_{23}) & (m_i^2 - \tilde{s}_{15}) \\
-\tilde{s}_{12} & 0 & 0 & 0 & (m_i^2 - \tilde{s}_{34}) \\
(m_i^2 - \tilde{s}_{45}) & (m_i^2 - \tilde{s}_{23}) & 0 & 2m_i^2 & (2m_i^2 - M_h^2) \\
0 & (m_i^2 - \tilde{s}_{15}) & (m_i^2 - \tilde{s}_{34}) & (2m_i^2 - M_h^2) & 2m_i^2
\end{pmatrix} \ . \quad (95)$$

Following Ref. [11], $E_{0_{p1}}$ can then be written as the linear combination of five scalar box integrals $D_{0_{p1}}^{(i)}$:

$$E_{0_{p1}} = -\frac{1}{2} \sum_{i=1}^{5} c_i D_{0_{p1}}^{(i)} \ , \quad (96)$$

where each $D_{0_{p1}}^{(i)}$ scalar box integral can be obtained from the scalar pentagon integral $E_{0_{p1}}$ of Eq. (92) in the limit where one of the Feynman parameters $a_i$ of the internal propagators goes to zero (i.e. $D_{0_{p1}}^{(i)}$ is obtained when $a_i \rightarrow 0$). The five box scalar integrals we need are given in Secs. A.1-A.5. The coefficients $c_i$ in Eq. (96) are given by:

$$c_i = \sum_{j=1}^{5} S_{ij}^{-1} \ . \quad (97)$$

Using Eq. (95) we can easily obtain them in terms of $m_t$, $M_h$, and the kinematic invariants $\tilde{s}_{ij}$. 36
The final result for the pentagon scalar integral $E_{0p1}$ can be written as:

$$E_{0p1} = \frac{i}{16\pi^2}N_t\left[\frac{X_2}{\epsilon^2} + \frac{X_1}{\epsilon} + X_0\right], \quad (98)$$

where $N_t$ is given in Eq. (13), while $X_{-2}$, $X_{-1}$ and $X_0$ are obtained using Eqs. (96)-(95), and the results in Secs. A.1-A.3. The expression for $X_0$ is too lengthy to be given explicitly in this appendix, while $X_{-2}$ and $X_{-1}$ have the following compact form:

$$X_{-2} = \frac{1}{2\sigma}\left(-\frac{1}{\omega_1\tau_1} - \frac{1}{\omega_2\tau_2} + \frac{2}{\tau_1\tau_2}\right),$$

$$X_{-1} = \frac{1}{\sigma\tau_1\tau_2}(-\Lambda_\sigma + \Lambda_{\omega_1} + \Lambda_{\omega_2} - \Lambda_{\tau_1} - \Lambda_{\tau_2}) + \frac{1}{\sigma\tau_2\omega_2}(\Lambda_{\tau_2} - \Lambda_{\tau_1} + \Lambda_{\omega_2}) +$$

$$+ \frac{1}{\sigma\tau_1\omega_1}(\Lambda_{\tau_1} - \Lambda_{\tau_2} + \Lambda_{\omega_1}),$$

where we have defined:

$$\sigma = (q_1 + q_2)^2 = s, \quad \tau_1 = m_1^2 - (q_1 - pt)^2 = 2q_1 \cdot pt = sqt,$$

$$\tau_2 = m_2^2 - (q_2 - p't)^2 = 2q_2 \cdot p't = s\bar{q}t,$$

$$\omega_1 = (p_t + p_h)^2 - m_1^2,$$

$$\omega_2 = (p'_t + p_h)^2 - m_2^2,$$

and

$$\Lambda_\sigma = \ln\left(\frac{\sigma}{m_1^2}\right), \quad \Lambda_{\tau_1} = \ln\left(\frac{\tau_1}{m_1^2}\right), \quad \Lambda_{\tau_2} = \ln\left(\frac{\tau_2}{m_1^2}\right), \quad (101)$$

$$\Lambda_{\omega_1} = \ln\left(\frac{\omega_1}{m_1^2}\right), \quad \Lambda_{\omega_2} = \ln\left(\frac{\omega_2}{m_1^2}\right).$$

We discuss in the following the box scalar integrals $D_{0p1}^{(1)}$, which are used in Eq. (96) to calculate $E_{0p1}$. The analogous box scalar integrals for $E_{0p2}$ can be obtained from the $D_{0p1}^{(1)}$ by exchanging $q_1 \leftrightarrow q_2$ in their analytic expression.

### A.1 Box scalar integral $D_{0p1}^{(1)}$

$D_{0p1}^{(1)}$ is obtained from the pentagon in the limit $a_1 \to 0$ and corresponds to the following integral:

$$D_{0p1}^{(1)} = \mu^{4-d} \int \frac{d^dk}{(2\pi)^d} \frac{1}{N_2N_3N_4N_5}$$

$$= \mu^{4-d} \int \frac{d^dk}{(2\pi)^d} \frac{1}{k^2(k+q_2)^2[(k+q_2-p'_t)^2-m_1^2][(k+q_2-p'_t-p_h)^2-m_2^2]},$$

37
after the momentum shift $k \rightarrow k - q_1$ has been applied to the denominators listed in Eq. (90). The part of $D_{p1}^{(1)}$ which contributes to the virtual amplitude squared is given by:

$$
D_{p1}^{(1)} = \frac{i}{16\pi^2} \mathcal{N}_t \left( -\frac{1}{\omega_2 \tau_2} \right) \left( \frac{X_{-2}}{\epsilon^2} + \frac{X_{-1}}{\epsilon} + X_0 \right),
$$

(103)

where $\mathcal{N}_t$ is given in Eq. (13), while the coefficients $X_{-2}$, $X_{-1}$, and $X_0$ are given by:

$$
X_{-2} = \frac{1}{2},
$$

(104)

$$
X_{-1} = \ln \left( \frac{\tau_1 m_t^2}{\omega_2 \tau_2} \right),
$$

$$
X_0 = \text{Re} \left\{ \frac{5}{6}\pi^2 + \ln^2 \left( \frac{\omega_2}{m_t^2} \right) + \ln^2 \left( \frac{\tau_2}{m_t^2} \right) - \ln^2 \left( \frac{\tau_1}{m_t^2} \right) \right\}
$$

+ $2 \ln \left( \frac{\omega_2 + \tau_1}{\omega_2} \right) \ln \left( \frac{\tau_1}{\omega_2} \right) + 2 \ln \left( \frac{\tau_2 - \tau_1}{\omega_2} \right) \ln \left( \frac{\tau_1}{\tau_2} \right)$

- $2 \text{Li}_2 \left( \frac{\tau_2 - \tau_1 - \omega_2}{\tau_2} \right) - 2 \text{Li}_2 \left( \frac{\omega_2 + \tau_1 - \tau_2}{\omega_2} \right) + 2 \text{Li}_2 \left( \frac{\tau_1 (\omega_2 + \tau_1 - \tau_2)}{\omega_2 \tau_2} \right) - I_0 \right\},
$$

(105)

where

$$
I_0 = \ln \left( \frac{\tau_2}{\tau_1} \right) \ln \left( \frac{M_h^2}{m_t^2} \right) + \left\{ -\text{Li}_2 \left( \frac{1}{\lambda_+} \right) + \ln \left( \frac{\tau_2}{\tau_1} \right) \ln \left( \frac{-\tau_1 - \lambda_+ (\tau_2 - \tau_1)}{\tau_2 - \tau_1} \right) \right\}
$$

- $\text{Li}_2 \left( \frac{\tau_2}{\lambda_+ (\tau_2 - \tau_1) + \tau_1} \right) + \text{Li}_2 \left( \frac{\tau_1}{\lambda_+ (\tau_2 - \tau_1) + \tau_1} \right) + (\lambda_+ \leftrightarrow \lambda_-) \right\},
$$

(106)

and

$$
\lambda_{\pm} = \frac{1}{2} \left( 1 \pm \sqrt{1 - \frac{4m_t^2}{M_h^2}} \right).
$$

(107)

### A.2 Box scalar integral $D_{p1}^{(2)}$

$D_{p1}^{(2)}$ is obtained from the pentagon in the limit $a_2 \rightarrow 0$ and corresponds to the following integral:

$$
D_{p1}^{(2)} = \mu^{4-d} \int \frac{d^d k}{(2\pi)^d} \frac{1}{N_1 N_3 N_4 N_5}
$$

$$
= \mu^{4-d} \int \frac{d^d k}{(2\pi)^d} \frac{1}{k^2 (k+q)^2 [(k+q-p_h)^2 - m_t^2][k+q-p_h-p_e]^2 - m_t^2]}
$$

(108)

$D_{p2}^{(2)}$ is equal to $D_{p1}^{(2)}$, and they both coincide with $D_{0b1}$ in Appendix [3.1].
A.3  Box scalar integral $D_{0p1}^{(3)}$

$D_{0p1}^{(3)}$ is obtained from the pentagon in the limit $a_3 \to 0$ and corresponds to the following integral:

\[
D_{0p1}^{(3)} = \mu^{4-d} \int \frac{d^d k}{(2\pi)^d N_1 N_2 N_4 N_5} \frac{1}{N_1 N_2 N_4 N_5} \]

\[
= \mu^{4-d} \int \frac{d^d k}{(2\pi)^d k^2(k + q_1)^2(k + q_1 + q_2)^2[(k + q_1 - p_t)^2 - m_t^2][(k + q_1 - p_t - p_h)^2 - m_t^2]},
\]

after the momentum shift $k \to -k - q_1$ has been applied to the denominators in Eq. (90). We notice that this integral can be obtained from $D_{0p1}^{(1)}$ when $q_2 \to q_1$ and $p_t' \to p_t$.

A.4  Box scalar integral $D_{0p1}^{(4)}$

$D_{0p1}^{(4)}$ is obtained from the pentagon in the limit $a_4 \to 0$ and corresponds to the following integral:

\[
D_{0p1}^{(4)} = \mu^{4-d} \int \frac{d^d k}{(2\pi)^d N_1 N_2 N_3 N_5} \frac{1}{N_1 N_2 N_3 N_5} \]

\[
= \mu^{4-d} \int \frac{d^d k}{(2\pi)^d k^2(k + q_1)^2[(k + q_1 + q_2)^2][(k + q_1 + q_2 - p_t)^2 - m_t^2]},
\]

after the momentum shift $k \to -k - q_1 - q_2$ has been applied to the denominators in Eq. (90). This integral coincides with $D_{0b3}^{(3)}$ in Appendix B.3.

A.5  Box scalar integral $D_{0p1}^{(5)}$

$D_{0p1}^{(5)}$ is obtained from the pentagon in the limit $a_5 \to 0$ and corresponds to the following integral:

\[
D_{0p1}^{(5)} = \mu^{4-d} \int \frac{d^d k}{(2\pi)^d N_1 N_2 N_3 N_4} \frac{1}{N_1 N_2 N_3 N_4} \]

\[
= \mu^{4-d} \int \frac{d^d k}{(2\pi)^d k^2(k + q_1)^2[(k + q_1 + q_2)^2][(k + q_1 + q_2 - p_t')^2 - m_t^2]},
\]

This integral coincides with $D_{0b3}^{(1)}$ in Appendix B.3.
B Box scalar integrals

B.1 Box 1 : box scalar integral $D_{0b_1}$

The scalar box integral $D_{0b_1}$ can be written as:

$$D_{0b_1} = \mu^{4-d} \int \frac{d^d k}{(2\pi)^d} \frac{1}{N_1 N_2 N_3 N_4}, \quad (112)$$

where

$$
N_1 = k^2, \\
N_2 = (k+q)^2, \\
N_3 = (k+q-p_t')^2 - m_t^2, \\
N_4 = (k+q-p_t'-p_h)^2 - m_t^2.
$$

The analytical expression for this integral can be found in Ref. [35]. Since the integral is finite, we have evaluated it in $d = 4$ dimensions using the FF package [24].

B.2 Box 2: box scalar integrals $D_{0b_2}^{(1)}$ and $D_{0b_2}^{(2)}$

The scalar box integral $D_{0b_2}^{(1)}$ can be written as:

$$D_{0b_2}^{(1)} = \mu^{4-d} \int \frac{d^d k}{(2\pi)^d} \frac{1}{N_1 N_2 N_3 N_4}, \quad (114)$$

where

$$
N_1 = k^2, \\
N_2 = (k+p_t)^2 - m_t^2, \\
N_3 = (k+p_t+p_h)^2 - m_t^2, \\
N_4 = (k-p_t')^2 - m_t^2
$$

while $D_{0b_2}^{(2)}$ is obtained from $D_{0b_2}^{(1)}$ by exchanging $p_t \leftrightarrow p_t'$. Therefore, all the following results for $D_{0b_2}^{(1)}$ can be easily extended to $D_{0b_2}^{(2)}$.

The part of $D_{0b_2}^{(1)}$ which contributes to the virtual amplitude squared is of the form:

$$D_{0b_2}^{(1)} = \frac{i}{16\pi^2} N_t \left( \frac{X_{-1}}{\epsilon} + X_0 \right) \frac{1}{(m_t^2 - \slashed{s}_{th}) \slashed{s}_t \slashed{s}_\ell}, \quad (116)$$

40
where $N_t$ is given in Eq. (13), while $s_{tt} = (p_t + p'_t)^2 = (q - p_h)^2 > 0$, $\beta_{tt} = \sqrt{1 - \frac{4m_t^2}{s_{tt}}}$, $\bar{s}_{th} = (p_t + p_h)^2$. The pole part $X_{-1}$ is:

$$X_{-1} = \ln\left(\frac{1 + \beta_{tt}}{1 - \beta_{tt}}\right),$$

while the finite part can be calculated using Ref. [30].

### B.3 Box 3: box scalar integrals $D_{b3}^{(1)}, D_{b3}^{(2)}, D_{b3}^{(3)},$ and $D_{b3}^{(4)}$

The scalar box integral $D_{b3}^{(1)}$ can be written as:

$$D_{b3}^{(1)} = \mu^{4-d} \int \frac{d^d k}{(2\pi)^d N_1 N_2 N_3 N_4} ,$$

where

$$N_1 = k^2,$$
$$N_2 = (k + q_1)^2,$$
$$N_3 = (k + q_1 + q_2)^2,$$
$$N_4 = (k + q_1 + q_2 - p_t')^2 - m_t^2 .$$

$D_{b3}^{(2)}$ is obtained from $D_{b3}^{(1)}$ by exchanging $q_1 \leftrightarrow q_2$. On the other hand, $D_{b3}^{(3)}$ arises from the box diagram where the Higgs boson is emitted from the antitop quark and corresponds to:

$$N_1 = k^2,$$
$$N_2 = (k + q_2)^2,$$
$$N_3 = (k + q_1 + q_2)^2,$$
$$N_4 = (k + q_1 + q_2 - p_t)^2 - m_t^2 .$$

Therefore $D_{b3}^{(3)}$ can be obtained from $D_{b3}^{(1)}$ by exchanging $q_1 \leftrightarrow q_2$ and $p'_t \leftrightarrow p_t$. Finally, $D_{b3}^{(4)}$ is obtained from $D_{b3}^{(3)}$ by exchanging $q_1 \leftrightarrow q_2$. We present here the case of $D_{b3}^{(1)}$. All other $D_{b3}^{(i)}$ boxes, for $i = 2, 3, 4$ can be obtained following the simple pattern of substitutions explained above.

The part of $D_{b3}^{(1)}$ which contributes to the virtual amplitude squared is given by:

$$D_{b3}^{(1)} = \frac{i}{16\pi^2} N_t \left( -\frac{1}{\sigma t_2} \right) \left( \frac{X_{-2}}{\epsilon^2} + \frac{X_{-1}}{\epsilon} + X_0 \right) ,$$

41
where $N_t$ is defined in Eq. (13), the coefficients $X_{-2}$, $X_{-1}$, and $X_0$ are given by:

$$X_{-2} = \frac{3}{2},$$

$$X_{-1} = \ln\left(\frac{\omega_1 m_t^4}{\sigma \tau_2^2}\right),$$

$$X_0 = 2 \ln\left(\frac{\tau_2}{m_t^2}\right) \ln\left(\frac{\sigma}{m_t^2}\right) - \ln^2\left(\frac{\omega_1}{m_t^2}\right) - 2 \text{Li}_2\left(1 + \frac{\omega_1}{\tau_2}\right) + \frac{\pi^2}{3},$$

and $\sigma$, $\tau_2$, and $\omega_1$ are defined in Eq. (100).

## C Phase space soft integrals

In this appendix we collect the integrals which we have used in calculating the results in Eq. (34) starting from Eq. (32). For a more exhaustive treatment of the formalism used we refer to Refs. [13, 29], from which the results in this appendix have been taken.

We parameterize the soft gluon $d$-momentum in the $q\bar{q}$ rest frame as:

$$k = E_g(1, \ldots, \sin \theta_1 \sin \theta_2, \sin \theta_1 \cos \theta_2, \cos \theta_1),$$

such that the phase space of the soft gluon in $d=4 - 2\epsilon$ dimensions can be written as:

$$d (PS_g)_{soft} = \frac{\Gamma(1-\epsilon)}{\Gamma(1-2\epsilon)(2\pi)^3} \int_0^{\delta_0} dE_g E_g^{1-2\epsilon} \int_0^{\pi} \sin^{1-2\epsilon} \theta_1 \int_0^{\pi} \sin^{1-2\epsilon} \theta_2.$$  

(124)

Then, all the integrals we need are of the form:

$$I_n^{(k,l)} = \int_0^{\pi} d\theta_1 \sin^{d-3} \theta_1 \int_0^{\pi} d\theta_2 \sin^{d-4} \theta_2 \frac{(a + b \cos \theta_1)^{-k}}{(A + B \cos \theta_1 + C \sin \theta_1 \cos \theta_2)^l}. \quad (125)$$

In particular we need the following four cases. When $A^2 \neq B^2 + C^2$, and $b = -a$, we use (dropping terms of order $O\left((d - 4)^2\right)$):

$$I_n^{(1,1)} = \frac{\pi}{a(A+B)} \left\{ \frac{2}{d-4} + \ln\left[\frac{(A+B)^2}{A^2-B^2-C^2}\right] \right\} + \frac{1}{2} \left[ \ln^2\left(\frac{A - \sqrt{B^2 + C^2}}{A + B}\right) - \ln^2\left(\frac{A + \sqrt{B^2 + C^2}}{A - \sqrt{B^2 + C^2}}\right) \right] \quad (126)$$

$$+ 2 \text{Li}_2\left(\frac{B + \sqrt{B^2 + C^2}}{A - \sqrt{B^2 + C^2}}\right) - 2 \text{Li}_2\left(\frac{B - \sqrt{B^2 + C^2}}{A + B}\right),$$

42
Finally, when $b \neq -a$ we use:

$$I^{(0,1)}_n = \frac{\pi}{\sqrt{B^2 + C^2}} \left\{ \ln \left( \frac{A + \sqrt{B^2 + C^2}}{A - \sqrt{B^2 + C^2}} \right) - (d - 4) \operatorname{Li}_2 \left( \frac{2\sqrt{B^2 + C^2}}{A + \sqrt{B^2 + C^2}} \right) + \frac{1}{4} \ln^2 \left( \frac{A + \sqrt{B^2 + C^2}}{A - \sqrt{B^2 + C^2}} \right) \right\} ,$$  \hspace{1cm} (127)

$$I^{(0,2)}_n = \frac{2\pi}{A^2 - B^2 - C^2} \left[ 1 - \frac{1}{2} (d - 4) \frac{A}{\sqrt{B^2 + C^2}} \ln \left( \frac{A + \sqrt{B^2 + C^2}}{A - \sqrt{B^2 + C^2}} \right) \right] .$$  \hspace{1cm} (128)

Finally, when $A^2 = B^2 + C^2$, and $b = -a$, we have:

$$I^{(1,1)}_n = 2\pi \frac{1}{aA} \frac{1}{d - 4} \left( \frac{A + B}{2A} \right)^{d/2 - 3} \left[ 1 + \frac{1}{4} (d - 4)^2 \operatorname{Li}_2 \left( \frac{A - B}{2A} \right) \right] .$$  \hspace{1cm} (129)

### D. Color ordered amplitudes for $h \rightarrow q\bar{q}t\bar{t} + g$

The tree-level amplitude for $h \rightarrow q(q_1)\bar{q}(q_2)t(p_t)\bar{t}(p_{\bar{t}})$ is explicitly given by:

$$A_{LO}^{h \rightarrow q\bar{q}t\bar{t}} = i \frac{m_t}{v} g_s^2 \delta_{f_qf_{\bar{q}}} \delta_{f_tf_{\bar{t}}} \left[ \bar{u}(q_1) \gamma^\nu T^a_{c_qc_{\bar{q}}} v(q_2) \right] \frac{1}{(p_h - p_t - p_{\bar{t}})^2} \times \left\{ \bar{u}(p_t) \left( \gamma^\nu \frac{\not{p}_h - \not{p}_{\bar{t}} + m_t}{(p_h - p_{\bar{t}})^2 - m_t^2} + \frac{-\not{p}_h + \not{p}_t + m_t}{(p_h - p_t)^2 - m_t^2} \gamma^\nu \right) T^a_{c_t c_{\bar{t}}} v(p_{\bar{t}}) \right\}$$  \hspace{1cm} (130)

where $p_h$ is taken as incoming, while all the other momenta are outgoing. Using the color decomposition given in Eq. (106), we have rewritten $A_{LO}^{h \rightarrow q\bar{q}t\bar{t}}$ in terms of a leading color and a sub-leading color ordered amplitude. Both amplitudes are given by:

$$A_0 = i \frac{m_t}{v} g_s^2 \left[ \bar{u}(q_1) \gamma^\nu v(q_2) \right] \frac{1}{(p_h - p_t - p_{\bar{t}})^2} \times \left\{ \bar{u}(p_t) \left( \gamma^\nu \frac{\not{p}_h - \not{p}_{\bar{t}} + m_t}{(p_h - p_{\bar{t}})^2 - m_t^2} + \frac{-\not{p}_h + \not{p}_t + m_t}{(p_h - p_t)^2 - m_t^2} \gamma^\nu \right) v(p_{\bar{t}}) \right\}$$  \hspace{1cm} (131)

$$A_{q\bar{q}}^{0,\nu} = \bar{u}(q_1) \gamma^\nu v(q_2) ,$$  \hspace{1cm} (132)

$$A_{t\bar{t}}^{0,\nu} = \bar{u}(p_t) \left( \gamma^\nu \frac{\not{p}_h - \not{p}_{\bar{t}} + m_t}{(p_h - p_{\bar{t}})^2 - m_t^2} + \frac{-\not{p}_h + \not{p}_t + m_t}{(p_h - p_t)^2 - m_t^2} \gamma^\nu \right) v(p_{\bar{t}}) .$$
The $\mathcal{O}(\alpha_s)$ real corrections to the Born amplitude consist of the process $h \to q\bar{q}t\bar{t} + g$, where the gluon can be emitted either from the external quark legs or from the internal gluon propagator. Therefore we can write $A^{h\to q\bar{q}t\bar{t}g}$ as follows:

$$A^{h\to q\bar{q}t\bar{t}g} = (ig_s)\delta_{f_f}^f\delta_{f_f}^f \left[A^\mu_q (T^a T^b)_{c_q c_q} T^c_{c_c c_c} + A^\mu_{\bar{q}} (T^{b^a} T^a)_{c_q c_q} T^b_{c_c c_c} + A^\mu_t T^b_{c_q c_q} (T^b T^a)_{c_c c_c} + A^\mu_g (i f^{abc} T^b_{c_q c_q} T^c_{c_c c_c}) \right] \cdot \epsilon^\mu(k) ,$$

where $\epsilon^\mu(k)$ is the polarization vector of the emitted gluon and we have defined by $A_i^\mu$ the part of the real amplitude corresponding to the emission of the gluon from $i = q, \bar{q}, t, \bar{t}, g$. More explicitly, the $A_i^\mu$ amplitudes are given by:

$$A_i^\mu = \left(g_s^2 m_t \right) \left(\bar{u}(p_i(\gamma^\mu q_i \gamma^a q_{i+1} \gamma^c q_{i+2} \gamma^b q_{i+3} \gamma^c v(q_2)) \frac{1}{(p_h - p_t - p_{t'}^2)^2 A_{i\mu}^0} \right) ,$$

$$A_i^\mu = \left(g_s^2 m_t \right) \left(\bar{u}(p_i(\gamma^\mu q_i \gamma^a q_{i+1} \gamma^c q_{i+2} \gamma^b q_{i+3} \gamma^c v(q_2)) \frac{1}{(p_h - p_t - p_{t'}^2)^2 A_{i\mu}^0} \right) ,$$

$$A_i^\mu = \left(g_s^2 m_t \right) \left(\bar{u}(p_i(\gamma^\mu q_i \gamma^a q_{i+1} \gamma^c q_{i+2} \gamma^b q_{i+3} \gamma^c v(q_2)) \frac{1}{(p_h - p_t - p_{t'}^2)^2 A_{i\mu}^0} \right) ,$$

$$A_i^\mu = \left(g_s^2 m_t \right) \left(\bar{u}(p_i(\gamma^\mu q_i \gamma^a q_{i+1} \gamma^c q_{i+2} \gamma^b q_{i+3} \gamma^c v(q_2)) \frac{1}{(p_h - p_t - p_{t'}^2)^2 A_{i\mu}^0} \right) ,$$

where

$$V_{3g}^{\mu\nu}(k, q_1, q_2) = (-2k^\rho - q^\rho)g^{\mu\nu} + (2g^\mu + k^\mu)g^{\nu\rho} + (-q^\nu - k^\nu)g^{\mu\rho} .$$

Using the color decomposition given in Eq. (133), we can also rewrite $A^{h\to q\bar{q}t\bar{t}g}$ as a linear combination of four color ordered amplitudes, as already given in Eq. (137). By matching the color factors in Eq. (133) to the color factors in Eq. (137), we see that the color ordered amplitudes $A_i(q_1, q_2, p_t, p_{t'}^2, k)$ (for $i = 1, \ldots, 4$) are given by (132):

$$A_1(q_1, q_2, p_t, p_{t'}^2, k) = \left( A_q^\mu + A_{\bar{q}}^\mu - A_t^\mu \right) \cdot \epsilon^\mu(k) ,$$

44
\[ \mathcal{A}_2(q_1, q_2, p_t, p'_t, k) = \left( \mathcal{A}^{\mu}_{\bar{q}} + \mathcal{A}^{\mu}_t + \mathcal{A}^{\mu}_{\bar{g}} \right) \cdot \epsilon_{\mu}(k) \]
\[ \mathcal{A}_3(q_1, q_2, p_t, p'_t, k) = \left( \mathcal{A}^{\mu}_{\bar{q}} + \mathcal{A}^{\mu}_{\bar{g}} \right) \cdot \epsilon_{\mu}(k) \]
\[ \mathcal{A}_4(q_1, q_2, p_t, p'_t, k) = \left( \mathcal{A}^{\mu}_{t} + \mathcal{A}^{\mu}_{\bar{t}} \right) \cdot \epsilon_{\mu}(k) \]
