Critical care demand and intensive care supply for patients in Japan with COVID-19 at the
time of the state of emergency declaration in April 2020: a descriptive analysis.

Keywords: severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2); The
coronavirus disease 2019 (COVID-19); intensive care unit (ICU); extracorporeal membrane
oxygenation (ECMO).

NOTE: This preprint reports new research that has not been certified by peer review and should not be used to guide clinical practice.
Abstract

Background: The coronavirus disease 2019 (COVID-19) pandemic, due to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), threatened to overwhelm Japan’s intensive care capacity due to the rising numbers of infected patients. This study aimed to determine the number of critically ill patients with COVID-19 who required intensive care, including mechanical ventilation and extracorporeal membrane oxygenation (ECMO), during the pandemic and to compare these patient numbers with Japan’s overall intensive care capacity.

Methods: Japanese Society of Intensive Care Medicine datasets were used to obtain the number of confirmed patients with COVID-19 who had undergone mechanical ventilation and ECMO between February 15 and June 4 2020, to determine and compare intensive care unit (ICU) and attending bed needs for patients with COVID-19, and to estimate peak ICU demands in Japan.

Results: In total, 17968 ICU days, 15171 mechanical ventilation days, and 2797 ECMO days were attributable to patients with COVID-19. There was a median (interquartile range) 143 (63-255) patients in ICU, 124 (51-225) patients on mechanical ventilation, and 18 (15-36) patients on ECMO machines. During the epidemic peak in late April, 11443 patients (1.03 per 10000 adults) had been infected, 373 patients (0.034 per 10000 adults) were in ICU, 312 patients (0.028 per 10000 adults) were receiving mechanical ventilation, and 62 patients (0.0056 per 10000 adults) were on ECMO machines per day. The number of infected patients at the peak of the epidemic was 651% of total designated beds and the number of patients requiring intensive care at the peak of the epidemic was 6.0% of total
ICU beds in Japan, 19.1% of total board-certified intensivists in Japan and 106% of total designated medical institutions for Category II infectious diseases in Japan, respectively.

**Conclusions:** Following the state of emergency declaration on April 7 2020, the number of patients with COVID-19 and the number of critically ill patients continued to rise, exceeding the number of designated beds but not exceeding ICU capacity. Urgent nationwide and regional planning is needed to prevent an overwhelming burden on ICUs in relation to critically ill patients with COVID-19 in Japan.
Introduction

A novel coronavirus, namely, severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), was first reported in Wuhan, China, in December 2019, and the number of newly reported cases has continued to increase globally. As at June 4 2020, >6.2 million cases had been reported worldwide and >300000 people had died [1], with 17000 Reported cases and nine deaths recorded in Japan. On January 30 2020, the World Health Organization (WHO) declared the epidemic to be a "public health emergency of international concern". On April 7 2020, Japan declared a state of emergency in seven major central cities, which then was extended to all 47 prefectures on April 16 2020 [2].

COVID-19 affects the respiratory system and patients infected with SARS-CoV-2 suffer from respiratory syndromes [3]. Although approximately 70-80% of patients with COVID-19 have mild to moderate symptoms and recover, 5-20% of patients develop severe respiratory failure and may require admission to an intensive care unit (ICU) [3-5].

Symptomatic treatment for severe respiratory failure has involved the use of mechanical ventilation and extracorporeal membrane oxygenation (ECMO) [5-9] as there are currently no specific drugs or other procedures available to treat patients with COVID-19. One study that analyzed clinical cases of COVID-19 reported a better prognosis in patients with mild infection, whereas the prognosis for patients with severe and critical infections is poor. However, patients presenting with mild infection are less obvious and are less easily located or identified [10]. A previous observational study reported that approximately 50% of the patients admitted to ICU required ventilation support and, of these, one in four patients required considerably greater levels of intensive life support [10]. A cohort study
found approximately 8% of patients with COVID-19 were critically ill [11]. One case series reported that, of 18 patients who required intubation, 1 patient required ECMO and 5 patients died [12]. It has been estimated that, despite intensive life support, approximately 3-4% of all infected patients are likely to die due to SARS-CoV-2 infection [3,13].

The importance of ICUs during the COVID-19 pandemic has been well established; however, ICU capacity in relation to expected numbers of patients with COVID-19 requiring intensive care is unknown. During the COVID-19 epidemic, there has been a dramatic surge in the number of critically ill patients with an urgent need for ICU admission [14], as occurred in other natural disasters [15,16]. An analysis of the epidemic peak in Wuhan indicated that the number of severely and critically ill adult patients requiring intensive care was estimated to be 12.2/10000 and 2.6/10000, respectively [17]. However, this situation clearly differs between countries, and specific data sourced in terms of Japanese circumstances are needed [18]. This study aimed to determine the number of critically ill patients who required ICU admission, including the number of patients requiring mechanical ventilation and ECMO, and to compare these patient numbers with ICU capacity in Japan at nationwide and regional levels.

Methods

Ethical approval

Institutional Review Board approval and patient informed consent were not required for this study, as this study did not involve human participant research or any interventions.
Permission to use the data and analysis was obtained from the Japanese Society of Intensive Care Medicine (JSICM) [19].

**Infectious disease data source**

We obtained data concerning numbers of infected, recovered, and dead patients due to COVID-19 in Japan from a publicly available website [20]. The number of patients who required mechanical ventilation and ECMO support was extracted from the JSICM website [18,19]. This database accumulates data using a CRoss Icu Searchable Information System (CRISIS). More than 570 facilities across Japan currently participate in this CRISIS, centering on facilities certified by the JSICM and facilities designated by the Japanese Society of Emergency Medicine, with a total of 5500 ICU beds, covering 80% of the total ICU beds in Japan [21]. This database provides information concerning the number of patients under mechanical ventilation, under ECMO, the number of patients in recovery from ECMO, and the number of patients who died during ECMO.

**Intensive care unit capacity data source**

We extracted the number of ICU beds (n = 7109) and board-certified intensivists (n = 1957) from the JSICM website. This website has also reported the estimated number of mechanical ventilators for adults (n = 30091) and ECMO machines (n = 2208) in Japan (Table 1) [22].

In Japan, COVID-19 was designated as an infectious disease under the Infectious Diseases Control Law on January 28 2020. Patients with COVID-19 were admitted and transferred
to designated medical institutions responsible for the hospitalization of patients with a
designated medical institutions responsible for the hospitalization of patients with a
Category II infectious disease (especially tuberculosis) or a novel influenza infection.

Although clear evidence of person-to-person airborne transmission of SARS-CoV-2 has not
been established, an airborne component of transmission is likely, based on other
respiratory viruses such as severe acute respiratory syndrome (SARS), Middle East
respiratory syndrome (MERS), and influenza [23-26] and its presence in aerosol has been
confirmed at RNA level [27,28]. Many infectious control guidelines recommend that
healthcare workers be protected through the use of personal protective equipment [29-31].
Suspicious airborne infectious routes make patient care difficult and complex, requiring the
management of the patient using airborne precautions [32] or management of the patient in
a depressurized area [31]. A patient management ratio of one critically ill patient to one
depressurized area per hospital has been used, assuming that not all infected patients could
be treated in ICU beds. In Japan, there are 1758 beds designated for patients with a
Category II infectious disease, 3502 beds allocated for patients with tuberculosis, and 351
designated medical institutions for patients with Category II infectious diseases (table 1)
[33].

ECMO is a highly integrated critical care treatment that requires multidisciplinary team
collaboration [34,35]. It is also assumed that not all of the ECMO machines in Japan could
be allocated to manage critically ill patients with COVID-19. In Japan, an organized
ECMO-based respiratory program, namely, the ECMO project [36], comprises a
consortium of specialized institutions for ECMO involving the participation of 100
hospitals in this project. We assumed these hospitals were the institutions specially
dedicated to treat critically ill patients with COVID-19 who required treatment using ECMO machines (table 1) [36].

Board-certified intensivists and patient numbers in ICUs in seven regions in Japan according to the JSICM and CRISIS

Data concerning population numbers in Japan in 2019 at nationwide and regional levels and the proportion of adults aged ≥15 years were retrieved from the Statistics Bureau of Japan [37]. The national population was \(1.26 \times 10^8\) and the proportion of adults was 87.9%. To determine regional differences, we analyzed the demand and supply of ICUs in the 47 prefectures. The JSICM and CRISIS have reported the number of board-certified intensivists and the number of patients in ICU in seven regions in Japan, namely, Hokkaido, Tohoku, Kanto-Koshinetsu, Tokai-Hokuriku, Kansai, Chugoku-Shikoku, and Kyusyu-Okinawa (figure 1). Data concerning the 47 prefectures were then integrated according to these seven regions (table 1).

Statistical analysis

The total number of patient days in ICU was summed to estimate the total number of ICU days and the raw number of patients in ICU on each day was plotted [17]. The notation “ICU” denoted the total number of patients on mechanical ventilator and ECMO. The proportion of critically ill patients per 10000 adults was estimated based on the number presented in the infectious diseases and ICU capacity data source sections.
Results

COVID-19 accounted for a total of 17968 ICU days, 15171 mechanical ventilation days, and 2797 ECMO days between January 15 2020 and June 4 2020, with a median (interquartile range [IQR]) of 143 (63-255) patients in ICU, 124 (51-225) patients on mechanical ventilation, and 18 (15-36) patients on ECMO machines each day during this 111-day period (Figure 2, Table 2). During the peak of the epidemic in late April 2020, 11443 patients (1.03 per 10000 adults) had been infected with SARS-CoV-2 and, of these, 373 patients (0.034 per 10000 adults) were admitted to ICU, 312 patients (0.028 per 10000 adults) were treated using mechanical ventilation, and 62 patients (0.0056 per 10000 adults) were treated using ECMO machines per day.

The number of infected patients at the peak of the epidemic was 651% of total designated beds for Category II infectious disease and 218% of total Category II with tuberculosis beds, and the number of patients requiring intensive care at the peak of the epidemic was 6.0% of total ICU beds in Japan, 19.1% of total board-certified intensivists in Japan, and 106% of total Category II institutions. The number of patients requiring ECMO at the peak of the epidemic was 3.2% of total board-certified intensivists in Japan, 17.7% of total Category II institutions, and 62% of total hospitals participating in ECMO project in Japan, respectively (figure 2 and table 3).

The number of total ICU days was 1307 (IQR, 7-11) in Hokkaido, 168 (0-3) days in Tohoku, 9741 (40-127) days in Kanto-Koshinetsu, 1044 (6-14) days in Tokai-Hokuriku, 4227 (8-65) days in Kansai, 302 (0-5) days in Chugoku-Shikoku, and 1179 (0-20) days in Kyusyu-Okinawa (figure 3 and table 2).
ICU demand compared with the proportion of board-certified intensivists greatly increased in Hokkaido (37.3% of total board-certified intensivists in Hokkaido), in Kanto-Koshinetsu (26.7%), and in Kansai (27.7%) compared with the overall demand in Japan (19.1%). ICU and mechanical ventilation demand overwhelmed the number of Category II institutions in Hokkaido (117% of total Category II institutions of ICU and 108% of total Category II institutions for mechanical ventilation), in Kanto-Koshinetsu (213% for ICU and 176% for mechanical ventilation), and in Kansai (262% for ICU and 241% for mechanical ventilation) (table 3). The number of patients requiring ECMO compared with the number of ECMO project hospitals was 125% in Hokkaido and a 106% in Kanto-Koshinetsu (figure 4 and table 3).

Discussion

The number of new patients diagnosed with COVID-19 continues to increase globally. Approximately 70-80% of patients infected with SARS-CoV-2 show mild to moderate respiratory symptoms; however, between 5% and 32% of these patients may develop severe symptoms and require ICU admission, of whom between 3% and 22% may require mechanical ventilation and between 0.5% and 5% may require oxygenation with ECMO [3,4,10,32,38-40]. Depending on the efficacy of infection control strategies, a shortage of ICU ventilators may or may not eventuate [41].

Exceeding hospital bed capacity would likely increase the community spread of SARS-CoV-2 and lead to decreased quality of healthcare and intensive care [17]. In China,
national lockdown, quarantine, and social distancing measures were adopted to control the
spread of infection, with >10000 beds designated for the isolation and treatment of patients
with confirmed COVID-19 by early February, 2020 [17]. Despite these efforts to control
the spread of infection, this did not lead to an immediate downturn in demand for
hospitalization in critical care units and in ICUs in China [17], and this situation has been
similar in Japan.

Our results indicated a critical need to isolate and treat patients with COVID-19; however,
while there remained a small margin for critically ill patients requiring mechanical
ventilation and ECMO in terms of ICU capacity, this situation was sub-optimal. Intensivists
do not necessarily attend to all critically ill patients, and have been reported to provide care
to only 37% of all ICU patients [42]. In the United States, one study reported that only
approximately 30% of intensive care units were staffed by dedicated intensivists [43]. We
have assumed that these percentages are likely to be the same or no greater in Japan. The
number of critically ill patients in ICU at the peak of the epidemic accounted for 19% of
total board-certified intensivists in Japan, which challenged Japan’s ICU capacity.

Our findings also showed a regional bias in terms of ICUs being overwhelmed in Japan.
Kanto-Koshinetsu and Kansai are the biggest regions in Japan. The Kanto-Koshinetsu
region includes Japan’s capital city, Tokyo, which is the most populous prefecture and also
includes Kanagawa, which is the second most populous prefecture. The Kansai region
includes Osaka, which is the third most populous prefecture. A large population and the
movement of people to and from these regions is thought to have spread the infection,
which resulted in medical capacity becoming overwhelmed. Hokkaido, the largest prefecture in Japan, had an increase in the number of patients with COVID-19 in the early phase of the epidemic. Epidemiological evidence to explain this phenomenon remains limited. Prior to the administration's state of emergency declaration, the local government in Hokkaido issued its own emergency declaration on February 28 2020 in an effort to control the spread of infection [44].

ECMO management in Japanese hospitals has previously resulted in poorer outcomes [45] compared with those reported in other countries during the N1H1 influenza epidemic [34,46-50]. There is wide consensus that ECMO treatment should be performed at centers with high case volumes and established protocols, and involving clinicians who are experienced in its use. Patients who require ECMO treatment should be transferred to appropriate ECMO centers [34,35,45,50]. Japan has introduced an ECMO project [36] and the ECMOnet [18,19], which involve a consortium working to promote the appropriate use of ECMO, to help develop an evidence-based foundation for its use, to strive for continued improvement in its application where appropriate, and to collect data concerning the number of patients requiring mechanical ventilation and ECMO support [51,52]. There are >2000 ECMO machines available for use in Japan. The number of patients requiring ECMO was 3.2% of all ECMO machines at the peak of the epidemic, but the capacity levels in terms of use should not be overestimated. In terms of the hospitals participating in the ECMO project in Japan, the number of patients requiring ECMO was 62% of their work at the peak of epidemic, which is likely to provide a more realistic estimate of their intensive care capacity.
Our study had several limitations. First, the number of critically ill patients requiring intensive care was not completely addressed in the JSICM database. This database has been estimated to capture >80% of clinical cases [19,21]; however, it relies heavily on the cooperation of physicians struggling to treat large numbers of critically ill patients.

Second, the extent of the ICU capacity was not completely validated nor was the number of patients requiring admission to ICUs. The JSICM reported the estimated number of ventilators and ECMO machines according to responses to a questionnaire sent to its member hospitals. Therefore, there was risk of overestimating ICU capacity. Third, the assumption of one critically ill patient to one depressurized area per hospital did not necessarily reflect the real life situation. For example, one author's institution was designated as a Category II infectious diseases institution with eight ICU beds, one depressurized area, and six Category II beds, with one board-certified intensivist. This institution was not a member of the ECMO project. Six Category II beds were fully occupied as soon as the number of infected patients threatened to overwhelm the capacity of the ICU, and other wards were then rearranged to manage patients with mild manifestations of COVID-19. There were two alternatives to treat critically ill patients with COVID-19: one was to use an ICU depressurized bed, and the other was to rearrange the beds in the emergency department. The latter option was chosen because other critically ill and surgical patients could not be treated in the ICU when occupied by patients with COVID-19 for fear of airborne transmissions. Most hospitals are thought to have flexibly employed a variety of methods to increase their capacity to treat patients with COVID-19.
Conclusion

During the COVID-19 pandemic and following the state of emergency declaration in Japan, the number of patients threatened to overwhelm the number of beds designated for infectious patients; however, Japan’s ICU capacity was sufficient to withstand the demands for mechanical ventilation and ECMO. However, there is no room for complacency in this situation. Urgent consideration is needed in relation to future planning concerning how to mitigate the threat to providing intensive care for critically ill patients with COVID-19 at domestic and regional levels in Japan.
Figure 1: Seven regions in Japan defined by The Japanese Society of Intensive Care Medicine. Seven regions are Hokkaido, Tohoku (Aomori, Iwate, Akita, Miyagi, Yamagata, and Fukushima), Kanto-Koshinetsu (Ibaraki, Tochigi, Gumma, Saitama, Chiba, Tokyo, Kanagawa, Niigata, Yamanashi, and Nagano), Tokai-Hokuriku (Toyama, Ishikawa, Fukui, Gifu, Shizuoka, Aichi, and Mie), Kansai (Shiga, Kyoto, Osaka, Hyogo, Nara, and Wakayama), Chugoku-Shikoku (Tottori, Shimane, Okayama, Hiroshima, Yamaguchi, Tokushima, Kagawa, Ehime, and Kochi), and Kyushu-Okinawa (Fukuoka, Saga, Nagasaki, Kumamoto, Oita, Miyazaki, Kagoshima, and Okinawa).
Figure 2: Burden of critical coronavirus disease during epidemic in Japan. (A) The number of infected and critically ill patients per 1000 adults. Critically ill patients were the sum of the number of the patients under mechanical ventilation and ECMO. Japanese government also declared “The State of Emergency” on 7 April 2020 for major central cities with a cumulative 4257 confirmed cases and 93 deaths among patients with COVID-19 and it spread to all of 47 prefectures on 16 April 2020. (B) The magnified version of figure A. Category II; designated medical institutions for Category II infectious diseases, TB; tuberculosis, ECMO; extracorporeal membrane oxygenation.

Table 3: The percentage of the number of patients requiring critical care, mechanical ventilation, and ECMO to the number of board-certified intensivists, Category II institutions, and ECMO project hospitals for each region in Japan at the peak of epidemic. ICU; intensive care unit, Category II; designated medical institution for Category II infectious diseases, TB; tuberculosis, ECMO; extracorporeal membrane oxygenation.
Abbreviations

WHO: World Health Organization; ECMO: Extracorporeal membranous oxygenation; COVID-19: Coronavirus induced disease 2019; JSICM: the Japanese Society of Intensive Care Medicine; IQR: interquartile range.

Authors’ contributions

YF and KH drafted the manuscript. YF analyzed the data. The author(s) read and approved the final manuscript.

Funding

This work was supported by the branding program as a world-leading research university on intractable immune and allergic diseases from MEXT Japan to K.H.

Acknowledgement

The authors appreciate the permission of use of data from the Japanese Society of Intensive Care Medicine. The authors would like to thank Editage (www.editage.com) for English language editing.

Availability of data and materials

The datasets used and analyzed during the current study are available from the corresponding author on reasonable request.
Ethics approval and consent to participate

Not applicable.

Consent for publication

Not applicable.

Competing interests

All authors report no conflicts of interest to declare.

The graph shows the percentage of patients requiring Extracorporeal Membrane Oxygenation (ECMO) in hospitals, relative to full capacity, across different regions in Japan from March 1 to June 1. The regions include Hokkaido, Kanto-Koshinetsu, Kansai, Tohoku, Tokai-Hokuriku, Chugoku-Shikoku, Kyusyu-Okinawa, and Japan. The y-axis represents the percentage of patients, while the x-axis shows the dates from March 1 to June 1. The full capacity line is indicated by the dashed horizontal line at 100%.
