Abstract: Much attention has been given to how we can make consumption more responsible—better for the planet and society. However, research on the associations between consumer purchasing behavior and their psychological concern for health, the environment and ethics lacks consensus on the significance and directionality of these concerns. This study aims to examine how (relatively) important these concerns are in determining consumer purchasing behavior. Systematic searches were conducted in PubMed, EconLit, Web of Science and Scopus databases from 2000 to 2020. Results were summarized through narrative synthesis of the evidence and meta-analysis. The meta-analysis revealed a significant positive correlation between health, environmental and ethical concerns and purchasing behavior, indicating that changes in health, environmental and ethical concerns will result in a consistent shift in purchase behavior towards choices consistent with the concern. This association is susceptible to moderating factors including types of products (food, non-food and non-specific products) and country’s level of economic development. In addition, the health, environmental and ethical concerns appear to have a weaker impact on the actual purchase behavior than on purchase intention, suggesting that interventions should focus on translating these “purchasing intentions” into actual purchasing behaviors. Narrative review of the studies that were not subject to meta-analysis showed good agreement, with almost all relationships reported having the same direction as those indicated by the meta-analysis. Overall, this study suggests that there is substantial potential for marketing strategies aimed at encouraging pro-health, pro-environment and ethical purchasing behaviors.

Keywords: health; environment; ethical concern; purchase behavior; meta-analysis

1. Introduction

We have become increasingly aware of the impact of our daily consumption on the environment, our health and the lives of others. Much attention has therefore been given to how we can become more responsible consumers and make more consumption choices that are good for the planet and society. Consumer behavior is a highly complex process, influenced not only by prices and income, but also by a variety of preferences, which can be broadly categorized as egoistic (e.g., concern about one’s health) and altruistic (e.g., concern about the physical environment and the ethical manner by which goods are produced (Birch et al. 2018; Ritter et al. 2015; Magnusson et al. 2003). However, there is no consensus on the directionality (positive, negative, or no effect) of these concerns on consumers’ purchasing behavior (Konuk 2019; Nguyen et al. 2020; Birch et al. 2018; Liao et al. 2020). A positive association would imply that an increase in health, environmental and ethical concerns will result in a shift in purchasing towards choices indicated by these concerns; for example, buying more healthy products or fewer unhealthy products. A negative association would imply that an increase in these concerns will move purchasing away...
from choices indicated by these concerns; for example, buying more unethical products or fewer ethical products. No effect indicates that a shift in health, environmental and ethical concerns will not influence purchasing.

Some studies have reported that health, environmental and ethical concerns have a significant positive impact on purchasing behavior (Wang et al. 2020; Yazar and Burucuoglu 2019; Magnusson et al. 2003), whereas others find no association (Michaelidou and Hassan 2008; Jin et al. 2020). One study found a significant negative impact of ethical concern on consumers’ purchasing intention towards genetically modified food (Kimenju and Groote 2008). The association between health, environmental and ethical concerns and a consumer’s purchase behavior also appears to differ across different types of purchase behavior, product category and country’s level of development (Yogananda Auroomooga and Nair 2019; Xu et al. 2020; Schill et al. 2019).

Consumer purchase behavior is an aggregation of a consumer’s attitudes, preferences, intentions and decisions in the marketplace (Armstrong and Kotler 2016; Li et al. 2019). Based on the theory of planned behavior (TPB), purchase behavior can be divided into three categories: purchase intention, purchase attitude and purchase decision (Ajzen 1991). Purchase intention refers to the subjective probability or possibility of a consumer purchasing a particular product but not the actual purchase (Wu Jinnan et al. 2020). Purchase attitude is a psychological tendency to purchase a product that is expressed by evaluating a particular entity with some degree of favor or disfavor but is not the actual purchase (Lin and Huang 2012). Purchase decision refers to the actual purchase of the product (Nawi et al. 2019). In addition, purchase frequency defines how often the consumer purchases a product (Farias 2019). The willingness to pay a premium price for a product has also been widely applied to studies of consumer purchasing behavior. As a result, we include it as a separate type of consumer purchase behavior parallel to the remaining purchase behaviors (Zhang Biao et al. 2018).

Studies have investigated the effect of health, environmental and ethical concerns on consumer’s purchase intention (Yogananda Auroomooga and Nair 2019), purchase attitude (Jin et al. 2020), purchase decision (Tan et al. 2019), purchase frequency (Kuhar and Juvancic 2010) and willingness to pay a premium price (Xu et al. 2020). These studies have had mixed results. For example, Kuhar and Juvancic (2010) found a positive association between health concern and customers’ purchase intentions (Chu 2018), while Birch et al. (2018) found there was no such association between health concern and customers’ purchase frequency.

There is also mixed evidence concerning the impact of product category—the type of product a customer is choosing to buy when making a purchasing decision. Depending on the product category, consumers perceive different levels of health, environmental and ethical concerns when making their purchasing decision. For example, a number of studies have assessed the association between health, environmental and ethical concerns and purchase behavior for food products (Wang et al. 2020) and non-food products (Xu et al. 2020) as well as non-specific product “categories” including green products such as eco-friendly items (Jin et al. 2020).

There is also a difference in purchasing behavior seen across levels of a country’s economic development, as people have different economic abilities to buy a product (Li et al. 2020). There have been studies examining the correlation between health, environmental and ethical concerns and purchase behavior in both high-income (Uzdavinyte et al. 2019; Schill et al. 2019) and low- and middle-income countries (Tong and Kang 2019; Malik et al. 2019), with mixed findings. Studies suggest a positive association between health concern and purchase behavior in some developing countries, such as Turkey (Yazar and Burucuoglu 2019), but no such association in others, such as Thailand (Sriwaranun et al. 2015). Finally, of course, methodologies used in investigating the correlation between health, environmental and ethical concerns and purchase behavior also vary (Fynn-Green et al. 2019; Prakash et al. 2018).
Overall, the clear lack of consensus with respect to the relationship between health, environmental and ethical concerns and purchase behavior (Yogananda Auroomooga and Nair 2019; Svecova and Odehnalova 2019; Shukla 2019) makes it difficult to design and assess marketing strategies to encourage pro-health, pro-environment or ethical purchasing behaviors. This study aims to fill the research gap by bringing together empirical evidence for the association between health, environmental and ethical concerns and consumer purchase behavior through meta-analysis and narrative review. The findings provide a robust estimate of the significance and directionality of relationships between consumer concerns and purchasing behaviors and a positive message for developing interventions intended to promote more responsible consumption.

2. Methods

This meta-analysis was conducted in accordance with the PRISMA flow guidelines for such reviews. The recommended protocol was followed.

2.1. Search Strategy and Study Selection

We conducted searches of both peer-reviewed scientific journals and “grey” literature identified from online databases. The search used keywords such as: “health concern”, “health conscious”, “environmental concern”, “environmental conscious”, “ethical conscious”, “ethical concern”, “purchase”, “shop”, “buy”, “factor”, “impact”, “effect”, “determine”, “drive” (Supplement S1). The PubMed, EconLit, Web of Sciences and Scopus databases were searched from January 2000 to March 2020, a two-decade period during which social attention towards health, environmental and ethical concerns has been growing and may be reflected in consumer purchase behavior (Ghvanidze et al. 2016; Ritter et al. 2015; Seyfang 2005).

2.2. Inclusion and Exclusion Criteria

The inclusion criteria were:
1. Articles published in English language;
2. Articles contain empirical data (including panel and cross-sectional data);
3. Studies should focus on at least one of the three concerns (health, environmental and ethical);
4. Studies should focus on consumer purchasing, including purchase intention, purchase attitude, purchase decision, purchase frequency and/or willingness to pay a premium price;
5. Purchasing was by consumers for themselves and/or for their households, not, e.g., corporate purchases by companies/organizations;
6. The subjects were adult consumers;
7. The geographic area/countries were not restricted.

Articles were excluded based on the following criteria:
1. Proceedings papers, qualitative studies, systematic reviews, experimental studies, and conceptual studies;
2. Studies focusing on product consumption, purchasing places (e.g., online shopping) or other decisions or behavior (e.g., conservation, openness to change, self-enhancement, and self-transcendence) that are not purchasing behavior;
3. Studies with moderating or indirect role of health, environmental and ethical concerns on purchasing behavior.

2.3. Data Extraction and Synthesis

Two reviewers independently screened titles and abstracts to identify studies that could be included and any conflicting opinions were adjudicated by a third reviewer. After title and abstract review, each article that met the inclusion criteria was reviewed in full and data were extracted with respect to: author(s), year of publication, concern (health, environmental and ethical), purchase attitude, purchase intention, purchase deci-
sion, purchase frequency and willingness to pay a premium price, methods to measure purchasing behavior, purchase product, methods to collect data, country or region, sample size, correlation coefficient, statistical methods to analysis data and the results.

2.4. Effect Size Computation

We selected Pearson’s correlation coefficient \( r \) for representing effect size (Card 2015). In some publications, extracting the necessary information for calculating a Pearson’s \( r \) was not possible (Supplements S2 and S3) and could not be included in our primary meta-analysis (Card 2015; Polman and Wu 2019). A positive \( r \) indicates a positive shift towards the decision indicated by the concern. The confidence intervals and hypothesis tests relating to \( r \) are usually carried out using the Fisher transformation, denoted as \( Z_r \):

\[
Z_r = \frac{1}{2} \ln \frac{1 - r}{1 + r}
\]

(1)

\( r \in [-1, +1] \)

(2)

Here, \( Z_r \) is the effect size and approximately follows a normal distribution with the standard error:

\[
SE_{Z_r} = \frac{1}{\sqrt{n - 3}} \text{ where } n \text{ is the sample size.}
\]

2.5. Risk of Bias Assessment

Risk of bias assessment was used to evaluate the quality of the 54 studies included in the meta-analysis. Six items adapted from previously developed risk of bias instruments (Li et al. 2020; Viswanathan et al. 2013) were employed in this study. For each item, the response options are no, yes and unclear (Table 1).

| Risk of Bias Criteria | Description                                                                 | Risk-\( \pi \) (%) |
|-----------------------|-----------------------------------------------------------------------------|---------------------|
| Selection bias        | Is there a random sampling in the study?                                    | 11 (20.37)          |
| Performance bias      | Do investigators and respondents know the purpose of the study?              | 0 (0)               |
| Detection bias        | Does the study report the reliability and validity of the measurement tool used in the study? | 4 (7.41) |
| Attribution bias      | Are there explanations for the proportion of valid questionnaires?           | 0 (0)               |
| Reporting bias        | Are the results of the study reported truthfully (e.g., both positive and negative results are reported?) | 18 (33.33) |
| Other bias            | Is there theoretical basis? Is there hypothesis development?                 | 4 (7.41)            |

3. Meta-Analysis

A random-effects model was adopted to create forest maps and funnel plots and to conduct heterogeneity analysis, meta-analysis, subgroup analyses and article weight analysis. The random effects model was selected due to its consistency with reality (Sriram 2018). First, the random effects model of Hedges was used to explain the heterogeneity between studies (Basu 2017). Second, heterogeneity was tested using the I-squared statistic.
($I^2$) and tested with a chi-squared test. A high $I^2$ statistic would mean gross heterogeneity, while a low $I^2$ value would imply homogeneity of the studies (usually conventionally set as 30%) (Basu 2017). Third, each study was weighted, and the effect size and confidence intervals were displayed in forest maps, along with the overall effect size. Fourth, subgroup analyses were conducted to examine the associations between the three concerns of interest and the types of purchase behavior (Murray et al. 2017). Fifth, moderator analyses were performed to investigate the influence of types of products and country development level on the associations between health, environmental and ethical concerns and customer purchase behavior (Li et al. 2020; Lin and Huang 2012); Table 2 presents a summary of each moderator’s classification. Sixth, publication bias was assessed through funnel plots. Finally, we assessed robustness by performing the fail-safe N test, which refers to the number of studies needed to reverse the results of the meta-analysis. It is considered difficult to change the meta-analysis results when the required studies exceed $5K + 10$ (K is the number of studies included) (Basu 2017). The fail-safe N test was conducted with Comprehensive Meta-Analysis version 3.0 (CMA 3.0). Significance was defined as $p < 0.01$ (two-sided). The remaining meta-analyses were conducted in Stata 16.0.
Table 2. Characteristics of the 54 studies included in the meta-analysis.

| Author (Year)               | Country     | Sample Size | Concern | Purchase Decision | Measure Purchase Decision | Product Category               |

Note: HC = Health concern, EnvC = Environmental concern, EC = Ethical concern.
4. Results

4.1. Review of the Studies Included in the Meta-Analysis

In total, 29,250 papers were initially identified based on the search strategy from four databases (see Supplement S1 for details) and three studies were retrieved from Google Scholar. After removal of duplicates, there were 18,156 articles left. Of these, 18,102 articles were excluded based on the inclusion and exclusion criteria and the remaining 104 articles were fully assessed. Of these, 50 articles did not report a correlation coefficient $r$ or were not able to calculate $r$ (Supplements S2 and S3), resulting in 54 articles that were finally included in the meta-analysis. Below is a flow diagram showing a summary of the search and selection process employed for identifying papers included in the meta-analysis (see Figure 1).

![Flow diagram](image-url)

**Figure 1.** The search and selection process for identifying papers included in the meta-analysis.

4.1.1. Publication Timeline and Geographical Scope

Of the 54 articles included in the meta-analysis, the annual number of articles published showed an increasing trend between 2015 and 2019 (Figure 2a), and a few studies were published in the remaining years (2008–2014). However, the effect sizes of the association between health and environmental concerns and purchasing behavior fluctuated between 2008 and 2020, indicating the effect sizes of the included studies did not appear to be related to time. The selected studies focused on a broader geographical scope including United States, United Kingdom, Europe and Asia and countries with different levels of economic development ranging from high-income economies including the USA, UK, France, Italy, Lithuania, Australia, to low- and middle-income economies including China, India, Iran, Kenya, South Korea, Malaysia, Pakistan, Bangladesh, Thailand, Turkey, Vietnam, Tanzania and Cambodia.
4.1.1. Publication Timeline and Geographical Scope

Of the 54 articles included in the meta-analysis, the annual number of articles published showed an increasing trend between 2015 and 2019 (Figure 2a), and a few studies were published in the remaining years (2008–2014). However, the effect sizes of the association between health and environmental concerns and purchasing behavior fluctuated between 2008 and 2020, indicating the effect sizes of the included studies did not appear to be related to time. The selected studies focused on a broader geographical scope including Unit ed States, United Kingdom, Europe and Asia and countries with different levels of economic development ranging from high-income economies including the USA, UK, France, Italy, Lithuania, Australia, to low- and middle-income economies including China, India, Iran, Kenya, South Korea, Malaysia, Pakistan, Bangladesh, Thailand, Turkey, Vietnam, Tanzania and Cambodia.

4.1.2. Purchase Product Category

Of the 54 studies included in the meta-analysis, 24 focused on food products, 18 focused on non-food products and the remaining 12 papers focused on non-specific products (where the paper did not state what the product was, such as various products described as “green” or “environmentally friendly”; these may be food and/or non-food products). Among the food purchasing behavior, the most investigated food product was organic food. The other, less discussed, food products were fair trade food, domestic food, functional food and healthy food. The most examined non-food products were electric vehicles, energy-efficient appliances, organic clothing, and organic cosmetics. Non-specific products included eco-friendly products, eco-labelled products and other green products, detailed in Table 2.

4.1.3. Dependent Variables Applied to Represent Purchase Behavior

Of the 54 studies, 36 selected purchase intention as representing the purchase behavior, 29 used purchase attitude, 5 purchase decision, 1 adopted purchase frequency and 4 studies adopted consumers’ willingness to pay a premium price for products. In line with the dependent variables, 23 studies adopted a five-point Likert scale and the remaining 31 studies used Likert-type scales to measure consumer purchase behavior. Sample sizes ranged from 50 to 9470 (Table 2).

4.1.4. Methods Used to Collect and Analyze Data

Of the 54 studies, 43 used structural equation modelling (SEM) to analyze the data. There were 10 studies that adopted regression methods to examine the relationship between health, environmental and ethical concerns and purchasing behavior. The remaining study applied a correlation analysis method to analyze the data (Table 2).

4.1.5. Results of Risk of Bias Assessment

The risk of bias assessment scores of the included studies in meta-analysis are shown in Table 1. The assessment had six specific aspects: selection, performance, detection, attribution, reporting and other bias. Overall, the included studies had low risk of publication bias, with approximately 4 papers with high scores (7.4%), and approximately 50 articles with low scores (92.6%).
4.1.6. Robustness Test

In terms of the association between health concern and consumer purchase behavior, the fail-safe N test shows that the number of missing studies that would bring $p$-value to $> \alpha$ (alpha = 0.01) is 4216, which is far more than 220 ($5K + 10$, where $K = 42$). With respect to the number of studies needed to reverse the results of the meta-analysis regarding the association between environmental concern and purchase behavior, 9428 articles are needed, which exceed 280 ($5K + 10$, where $K = 54$). The results mean that even if there was publication bias, it had little impact on the results and was tolerable and negligible.

4.2. Results Regarding the Effect of Health, Environmental and Ethical Concerns on Purchase Behavior

4.2.1. The Effect of Health Concern on Purchase Behavior

Of the 54 articles included in the meta-analysis, 29 addressed the effect of health concern on purchasing behavior and reported a correlation coefficient for the relationship between them. The correlation coefficient varied from 0.038 to 0.65. The statistical heterogeneity across the studies was high ($I^2$ percent, $p < 0.001$, $Q = 747.12$). The overall effect size between health concern and consumer purchase behavior was 0.38, with a 95% confidence interval ranging from 0.32 to 0.44. More specifically, all of the 29 studies reported a positive impact of health concern on consumer purchase behavior. The complete collection of information is summarized in Figure 3 and Table 2. The unsymmetrical funnel plot shown in Figure 4 led us to conduct robustness analysis (described in the above section).
reported a positive impact of health concern on consumer purchase behavior. The complete collection of information is summarized in Figure 3 and Table 2. The unsymmetrical funnel plot shown in Figure 4 led us to conduct robustness analysis (described in the above section).

**Figure 3.** Meta-analysis of the association between health concern and consumer purchase behavior.

**Random-effects Hedges model**

*Figure 3.** Meta-analysis of the association between health concern and consumer purchase behavior.
Figure 4. Funnel plot of the 29 articles investigated the association between health concern and consumer purchase behavior.

4.2.2. The Effect of Environmental Concern on Purchase Behavior

Of the 54 articles included, 39 addressed the association between environmental concern and customer purchase behavior and reported a correlation coefficient for the relationship between them (72.2%). The correlation coefficient varied from 0.05 to 0.74. The statistical heterogeneity across the studies was high ($I^2 = 93.13\%$, $p < 0.001$, $Q = 921.19$). The overall effect size between environmental concern and customer purchase behavior was 0.45, with a 95 percent confidence interval ranging from 0.39 to 0.50. More specifically, all of the 39 studies reported that the environmental concern had a positive impact on consumer purchase behavior. The complete collection of information is summarized in Figure 5 and Table 2. The unsymmetrical plot is shown in Figure 6 and the robustness test illustrates that publication bias in the findings (if there is any) is sufficiently small that it can be ruled out as a potential concern.

4.2.3. The Effect of Ethical Concern on Purchase Behavior

Of the 54 studies, only 1 addressed the effect of ethical concern on purchase behavior and reported a correlation coefficient for the relationship between them. The correlation coefficients were 0.43 and 0.65. The statistical heterogeneity was high ($I^2 = 85.92\%$, $p < 0.001$, $Q = 7.10$). The overall effect size between ethical concern and customer purchase behavior was 0.55, with a 95 percent confidence interval ranging from 0.38 to 0.72. Overall, ethical concern had a positive impact on customer purchase behavior in the included study. The complete collection of information is summarized in Figure 7 and Table 2. The symmetrical plot shown in Figure 8 illustrates no publication bias in our data regarding the association between ethical concern and consumer purchase behavior.
Figure 5. Meta-analysis of the association between environmental concern and consumer purchase behavior.

Random-effects Hedges model

Figure 5. Meta-analysis of the association between environmental concern and consumer purchase behavior.
4.2.3. The Effect of Ethical Concern on Purchase Behavior

Of the 54 studies, only 1 addressed the effect of ethical concern on purchase behavior and reported a correlation coefficient for the relationship between them. The correlation coefficients were 0.43 and 0.65. The statistical heterogeneity was high ($I^2 = 85.92\text{\%}$, $p < 0.001$, $q = 7.10$). The overall effect size between ethical concern and customer purchase behavior was 0.55, with a 95\% confidence interval ranging from 0.38 to 0.72. Overall, ethical concern had a positive impact on customer purchase behavior in the included study. The complete collection of information is summarized in Figure 7 and Table 2. The symmetrical plot shown in Figure 8 illustrates no publication bias in our data regarding the association between ethical concern and consumer purchase behavior.

### Figure 7. Meta-analysis of the association between ethical concern and consumer purchase behavior.

| Study       | Effect Size with 95\% CI | Weight (%) |
|-------------|--------------------------|------------|
| Konuk (2019)| 0.63 [ 0.54, 0.72]       | 50.00      |
| Konuk (2019)| 0.46 [ 0.37, 0.55]       | 50.00      |
| **Overall** | 0.55 [ 0.38, 0.72]       |            |

Random-effects Hedges model

4.2.4. Results of the Impact of Health, Environmental and Ethical Concerns on Different Types of Purchase Behavior

Of the 29 studies that investigated the relationship between health concern and purchase behavior, the overall effect size in purchase intention was 0.38. The overall effect size was 0.39 for purchase attitude, 0.17 for purchase frequency, and 0.56 for willingness to pay a premium price. The results indicate that health concern has a positive influence on purchase intention, purchase attitude, purchase frequency and willingness to pay a premium price.
Of the 39 studies that investigated the association between environmental concern and consumer purchase behavior, the overall effect size in customer purchase intention, purchase attitude, purchase decision, purchase frequency and willingness to pay a premium price was 0.44, 0.48, 0.43, 0.26 and 0.4, respectively, illustrating environmental concern has a positive impact on purchase intention, purchase attitude, purchase decision, purchase frequency and willingness to pay a premium price.

Only one study investigated the correlation between ethical concern and purchase behavior. It reported a correlation between ethical concern and purchase intention, and between ethical concern and willingness to pay a premium price, with effect sizes of 0.63 and 0.55, respectively. The overall association between ethical concern and consumer purchase behavior is positive.

4.3. Results for Moderators

As there was considerable variance between studies \( Q = 747.12, I^2 = 93.49 \) percent for health concern; \( Q = 921.19, I^2 = 93.13 \) percent for environmental concern; \( Q = 7.10, I^2 = 85.92 \) percent for ethical concern), subgroup analyses were conducted to explore heterogeneity by showing how effect sizes differed between groups of studies. Study-level characteristics included types of purchase behavior, product category and country’s economic development level. Subgroup analyses found significant differences for types of purchase behavior, product category and country’s economic development level \( p < 0.01 \), as presented in Table 3.

4.3.1. Types of Products

The effect size differed among types of products. In general, the effect size in non-food products was stronger than that in food products with regard to the association between health concern and purchase behavior. However, the effect size in food products was stronger than that in non-food products with respect to the correlation between environmental concern and consumer purchase behavior.

Of the 29 studies examining the association between health concern and purchase behavior, the overall effect size in food, non-food and non-specific product was 0.38, 0.42 and 0.18, respectively. Of the 39 studies investigating the relationship between environmental concern and purchase behavior, the overall effect size was highest in food (0.46) and lowest in non-food (0.43), and the non-specific product had an overall effect size of
0.45. The single study investigating the relationship between ethical concern and purchase behavior focused on food, with an overall effect size of 0.55.

Table 3. The overall effect sizes and heterogeneity analysis of the association between health, environmental and ethical concerns and purchase behavior by types of purchase behavior, product category and country’s development level.

| Type                                | Effect Size         | HC a | EnvC a | EC a |
|-------------------------------------|---------------------|------|--------|------|
| Types of purchase behavior          |                     |      |        |      |
| Purchase intention                  | 0.38 (29, 93.49%)   | 0.45 (39, 93.13%) | 0.55 (1, 85.92%) |
| Purchase attitude                   | 0.39 (18, 92.23%)   | 0.48 (20, 92.69%) |      |
| Purchase decision                   |                     | 0.43 (5, 94.14%)  |      |
| Purchase frequency                  | 0.17 (1, NA)        | 0.40 (1, NA)      |      |
| Willingness to pay a premium price  | 0.56 (1, NA)        | 0.26 (4, 71.84%)  | 0.55 (1, 85.92%) |
| Product category                    | 0.38 (29, 93.49%)   | 0.45 (39, 93.13%) | 0.55 (1, 85.92%) |
| Food                                | 0.38 (20, 92.5%)    | 0.46 (12, 95.38%) | 0.55 (1, 85.92%) |
| Non-food                            | 0.42 (8, 95.56%)    | 0.43 (16, 88.73%) |      |
| Non-specific products               | 0.18 (1, NA)        | 0.45 (11, 93.9%)  |      |
| Country development level           | 0.38 (29, 93.49%)   | 0.45 (39, 93.13%) | 0.55 (1, 85.92%) |
| Developing                          | 0.43 (22, 94.12%)   | 0.46 (32, 92.82%) | 0.55 (1, 85.92%) |
| Developed                           | 0.22 (7, 72.21%)    | 0.32 (7, 91.71%)  |      |

Note: a HC = Health concern, EnvC = Environmental concern, EC = Ethical concern; Number of publications and I-squared statistic of the heterogeneity analysis are displayed in brackets, NA refers to ‘not accessible’.

4.3.2. Country Economic Development Level

The effect size differed by country’s level of economic development. Overall, the effect sizes of the association between health, environmental and ethical concerns and purchase behavior in low- and middle-income countries were stronger than that in higher-income countries.

Of the 29 studies examining the association between health concern and purchase behavior, the overall effect size in low- and middle-income countries was 0.43. However, the overall effect size in high-income countries was 0.22. Of the 39 studies investigating the correlation between environmental concern and purchase behavior, the overall effect size in low- and middle-income countries was 0.46, and 0.32 in high-income countries. The single study examining the effect of ethical concern on customer purchase behavior was conducted in Turkey, a middle-income country. The overall effect size was 0.55.

4.4. Results of the 50 Articles Not Included in the Meta-Analysis

4.4.1. Descriptive Characteristics

Of the 50 articles not included in the meta-analysis, the trend pattern of annual numbers of publications was consistent with that of 54 studies included in the meta-analysis (Figure 2b). The association between health, environmental and ethical concerns and purchase behavior fluctuated and did not appear to be related to time. The investigated products in the 50 articles had the same characteristics with that of 54 studies, with 25 focused on food, 10 on non-food products and the remaining 15 studies examining non-specific products (Supplement S2). Additionally, the most investigated food product was organic food and the most studied non-food product was electric vehicles.

The dependent variables applied to represent purchase behavior in the 50 studies were consistent with that of 54 articles, with 24 purchase intention, 12 purchase attitude, 9 purchase decision, 4 purchase frequency and 5 willingness to pay a premium price (Supplement S2). All of these studies used either Likert scale or Likert-type scale to measure purchase behavior and the sample sizes ranged from 101 to 7627.
Of the 50 articles, 21 adopted the SEM method, 27 employed the regression method and the remaining 2 used correlation analysis to analyze data (Supplement S2). Questionnaire was the only method employed to collect primary data.

4.4.2. Results of the Association between Health, Environmental and Ethical Concerns and Purchase Behavior

Of the 50 studies that did not report Pearson’s r or were not able to compute Pearson’s r, 25 investigated the association between health concern and customer purchase behavior and reported a regression or pathway coefficient (shortened as coefficient in this section). Of the 25 studies, 21 reported a positive coefficient (84%) and only 4 reported a negative coefficient, indicating the overall effect of health concern on customer purchase behavior was positive, which supports the results of the meta-analysis.

Of the 50 studies, 41 examined the association between environmental concern and customer purchase behavior and reported a coefficient. Of these 41 studies, 36 reported a positive coefficient (90%) and only 5 reported a negative coefficient, indicating the overall effect of environmental concern on customer purchase behavior was positive, which supports the results of the meta-analysis.

Of the 50 studies, 3 investigated the association between ethical concern and customer purchase behavior, with 2 reporting a positive coefficient (66.7%) and 1 reporting a negative coefficient, indicating that ethical concern had an overall positive impact on customer purchase behavior, which also supports the meta-analysis results.

Of the 25 studies that investigated the association between health concern and purchase behavior, 21 studies reported a positive coefficient in purchase intention, purchase attitude, purchase decision, purchase frequency and willingness to pay a premium price, only 2 reported a negative coefficient in purchase attitude and 2 in purchase intention, indicating an overall positive association between health concern and consumer purchase behavior (purchase intention, purchase attitude, purchase decision, purchase frequency and willingness to pay a premium price), which supports the results of the meta-analysis.

Of the 41 studies that examined the association between environmental concern and purchase behavior, 36 studies reported a positive coefficient for customer purchase intention, purchase attitude, purchase decision, purchase frequency and willingness to pay a premium price, suggesting an overall positive correlation between environmental concern and consumer purchase behavior (purchase intention, purchase attitude, purchase decision, purchase frequency and willingness to pay a premium price). Only two studies reported a negative coefficient in purchase attitude, one in purchase intention, one in purchase frequency, and one in willingness to pay a premium price, which also supports the results of the meta-analysis.

Of the three studies that investigated the association between ethical concern and consumer purchase behavior, two found a positive coefficient in purchase attitude and willingness to pay a premium price, and one found a negative coefficient in purchase intention. These results suggest that the overall correlation between ethical concern and consumer purchase behavior is positive, which also supports the results of the meta-analysis.

When looking at the results from the moderator perspective, the results were also consistent with that of 54 studies included in the meta-analysis. With regard to the association between health concern and customer purchase behavior for food products, 3 found a negative coefficient, and the remaining 18 reported a positive coefficient. In terms of the association between health concern and customer purchase behavior for non-specific products, one reported a negative coefficient, and the remaining two reported a positive coefficient. Only one study investigated the association between health concern and customer purchase behavior for non-food products, and reported a positive coefficient. These results were consistent with that in meta-analysis. With regard to the association between environmental concern and consumer purchase behavior, 36 studies found a positive coefficient in food (13), non-food (10) and non-specific products (13), and only 3 articles found a negative coefficient in food products and 2 in non-specific products, which also support
the results of the meta-analysis. All of the three studies that investigated the correlation between ethical concern and purchase behavior focused on food, and two reported positive coefficients and one reported negative, which also support the results of the meta-analysis.

When it comes to country's level of economic development, four negative coefficients were found in the association between health concern and purchase behavior in low- and middle-income countries, and five in the association between environmental concern and purchase behavior in low- and middle-income countries. As a result, the remaining 43 articles reported a positive coefficient between health and environmental concern and purchase behavior in all countries, which also support the results of the meta-analysis.

5. Discussion

5.1. Summary of Findings

The findings of the meta-analysis indicate a direct and positive correlation between health, environmental and ethical concern and customer purchasing behavior, with overall effect sizes of 0.38, 0.45 and 0.55, respectively. Evidence suggests that these associations are moderated by types of products and country's level of economic development, suggesting that contextual factors (e.g., relative wealth, education, and cultural variation) are likely to impact consumer purchasing behavior. This moderating relation has not been explored in previous reviews. The overall effect size of the association between health concern and willingness to pay a premium price had the strongest correlation, followed by purchase attitude and purchase intention, and the purchase frequency had the least correlation with health concern. The overall effect size of the association between environmental concern and purchase attitude was the highest, followed by purchase intention, purchase decision and willingness to pay a premium price, and the lowest was purchase frequency. Ethical concern had a correlation with purchase intention. These results indicate that the health, environmental and ethical concerns have a weaker impact on the actual purchase behavior (i.e., purchase decision) than on non-actual purchase behavior (e.g., purchase attitude and purchase intention).

The number of studies in this area has increased in recent years, with around 70% published since 2015. However, the association between health, environmental and ethical concerns and purchase behavior did not appear to be related to time. A considerable majority of studies were undertaken in middle-income countries, especially in China, India and Malaysia. The most studied concern for consumer purchasing behavior was environmental, followed by health concern, and then, ethical concern. Approximately 30% of studies examined the association between both the health and environmental concerns and purchasing behavior. Almost half of the included studies investigated the association between health, environmental and ethical concerns and purchasing behavior concerning food products. Most studies adopted Likert scale or Likert-type scale to measure consumer purchasing behavior, and many employed Structural Equation Models (SEMs) to analyze the data.

Alongside the meta-analysis, we also studied a body of literature that used different statistical coefficients to report the relationship between health, environmental and ethical concerns and consumer purchasing behavior. Since these studies did not report their results using Pearson's r, we were not able to include them in the meta-analysis. However, we considered these additional 50 studies alongside the 54 studies included in our meta-analysis to give breadth to our analysis. The findings showed good agreement; in almost all cases, the direction of the relationships reported was the same as those given in the meta-analysis. This gives additional support to our meta-analysis findings.

5.2. Relationship to Previous Literature

To our knowledge, this is the first meta-analysis and narrative review to summarize the impact of health, environmental and ethical concerns on customer purchasing behavior. Previous studies have attempted such a review for health motives and the purchase of organic food (Rana and Paul 2020), the determinants of green purchases (Liobikiene and
Bernatoniené 2017), consumers’ willingness to pay for organic food (Li et al. 2019; Rana and Paul 2017, 2020), words–deeds gaps in the purchase of fair trade products (Kossmann and Gomez-Suarez 2019), interventions targeting conscious determinants of human behavior to reduce the demand for meat (Bianchi et al. 2018; Moreira et al. 2017), or have focused on a specific geographic region, such as purchasing of organic produce by South African consumers (Fynn-Green et al. 2019), green purchase intentions in Indian consumers (Nath et al. 2017), and green purchasing behaviors of Malaysian consumers (Goh and Wahid 2015). So far, none have attempted to integrate all three concerns, for a variety of purchasing behaviors, and with worldwide coverage. Our synthesis of existing studies should provide a firm basis for other researchers to extend the study of the relationships between health, environmental and ethical concerns and customer purchasing behavior.

5.3. Limitations and Future Research

However, many additional questions remain and could be addressed in future research work. First, few of the studies reviewed have investigated the association between ethical concern and customer purchasing behavior, indicating future research might focus on this topic. Second, the association between health, environmental and ethical concerns and consumer purchase behavior in non-food products and conducted in high-income countries needs additional empirical evidence. Third, other techniques than SEM methods should be introduced to provide a complete relation between these concerns and consumer purchase decisions. Fourth, statistical spatial data might provide more concise conclusions with respect to the association between health, environmental and ethical concerns and purchase decisions. Fifth, there was a large degree of heterogeneity and moderator analyses did not explain all variability. Sixth, many factors other than health, environmental and ethical concerns, such as the family and social context as well as the ability to access products that are considered healthy, ethical, and sustainable, may also influence purchasing behavior and should be considered in future research. In addition, our research was limited to publications in the English language. Despite these limitations, this study provides valuable evidence regarding the effects that health, environmental and ethical concerns have on customer purchase behavior.

6. Conclusions

This meta-analysis and narrative review bring together empirical evidence for the association between health, environmental and ethical concerns and consumer purchase behavior. The results reveal a direct and positive correlation between health, environmental and ethical concern and purchasing behavior, indicating that an increase in health, environmental and ethical concerns will result in a shift of purchasing towards choices indicated by these concerns. However, the association is moderated by factors including types of products (food, non-food and non-specific products) and country’s level of economic development. In addition, these concerns have a weaker impact on the actual purchase behavior than on non-actual purchase behavior (e.g., purchase attitude).

Our findings fill the research gaps in the lack consensus on the significance and directionality of the associations between consumer purchasing behavior and their psychological concern for health, the environment and ethics as well as the relative importance of these concerns in determining consumer purchasing behavior. Additionally, this study provides important insights for marketing managers, governmental bodies, policy makers, product producers and retailers to develop interventions intended to promote more responsible consumption. First, the findings may help practitioners to assess and develop intervention strategies aimed at improving consumers’ health, or promoting pro-environmental and/or ethical consumer purchasing behavior. Second, policies and marketing strategies can guide consumers to make more responsible consumption choices that are better for the planet and society by improving consumers’ health, environmental and ethical concerns. Third, it appears here that consumer concerns over health, environmental issues and ethical consumption are mostly reflected in non-actual purchase behavior, so intervention strategies...
could focus on translating these “good intentions” into actual purchasing decisions. Fourth, the evidence provided here suggests that people may change purchasing decisions for health, environmental and ethical reasons, rather than purely based on price, suggesting that marketing and policy interventions might utilize these concerns alongside or instead of price.
