FERMIONIC 6J-SYMBOLS IN SUPERFUSSION CATEGORIES

ROBERT USHER

Abstract. We describe how the study of superfusion categories (roughly speaking, fusion categories enriched over the category of super vector spaces) reduces to that of fusion categories over sVect, in the sense of [DGNO10]. Following [BE16], we give the construction of the underlying fusion category of a superfusion category, and give an explicit formula for the associator in this category in terms of 6j-symbols. We give a definition of the π-Grothendieck ring of a superfusion category, and prove a version of Ocneanu rigidity for superfusion categories.

1. Introduction

In condensed matter physics, the use of fusion categories to construct topological quantum field theories is reasonably well understood. In [TV92] and [Tur94], Turaev and Viro constructed invariants of 3-manifolds from quantum 6j-symbols, and showed that these lead to a 3-dimensional non-oriented topological quantum field theory. Barrett and Westbury [BW96] showed that these invariants can be constructed from any spherical fusion category. Following this, Kirillov and Balsam [KB10], and Turaev and Virelizier [TV10] proved that the Turaev-Viro-Barrett-Westbury invariants of a spherical fusion category $\mathcal{A}$ are the same as the Reshetikhin-Turaev invariants $\mathcal{Z}(\mathcal{A})$.

More recently, Douglas, Schommer-Pries and Snyder [DSS13] showed that fusion categories are fully dualizable objects in the 3-category of monoidal categories, and so by the cobordism hypothesis [Lur09] we can associate a fully local 3-dimensional TQFT to any fusion category.

Gaiotto and Kapustin [GK15], following the work of Gu, Wang and Wen [GWW10] described a fermionic analogue of the Turaev-Viro construction whose initial data is a spherical superfusion category, and Bhardwaj, Gaiotto and Kapustin [BGK16] have further studied spin-TQFTs. In comparison to the fusion category case however, not much is known about how to construct TQFTs using superfusion categories.

A superfusion category over $k$ is a semisimple rigid monoidal supercategory (i.e. a category enriched over $sVect$) with finitely many simple objects and finite dimensional superspaces of morphisms, with simple unit object. In particular, the collection of morphisms between objects forms a super vector space, and the tensor product of morphisms satisfies the super interchange law

\[(f \otimes g) \circ (h \otimes k) = (-1)^{g|h}(f \circ h) \otimes (g \circ k)\]
Following [GWW10], a simple object \( X \) is called \textit{Bosonic} if \( \text{End}(X) \cong k^{10} \), and \textit{Majorana} if \( \text{End}(X) \cong k^{11} \). A superfusion category is called \textit{Bosonic} if all of its simple objects are Bosonic. Since the unit object in any superfusion category is necessarily Bosonic, there are no Majorana superfusion categories.

In this paper, we give the construction of the \textit{underlying fusion category} of a superfusion category, using a construction described by Brundan and Ellis [BE16]. The underlying fusion category of a superfusion category is naturally endowed with the structure of a fusion category over \( \text{sVect} \) (in the sense of [DGNO10, Definition 7.13.1]), the category of super vector spaces together with the even linear maps between them.

The associator in a semisimple tensor category (in particular, a fusion category) admits a description in terms of \( 6j \)-\textit{symbols} satisfying a version of the pentagon equation, see i.e. [Tur94], [Wan10]. In a similar way, the associator in a superfusion category can be described in terms of \textit{fermionic} \( 6j \)-\textit{symbols} satisfying the \textit{super pentagon equation} [GWW10].

The main goal of this paper is to describe the relation between a superfusion category and its underlying fusion category. More precisely, we give an explicit formula for the \( 6j \)-\textit{symbols} of the underlying fusion category in terms of the fermionic \( 6j \)-\textit{symbols} of the superfusion category, and show that these \( 6j \)-\textit{symbols} satisfy the pentagon equation.

If \( \mathcal{C} \) is a Bosonic pointed superfusion category, i.e. a Bosonic superfusion category such that the isomorphism classes of simple objects form a group \( G \), then the fermionic \( 6j \)-\textit{symbols} in \( \mathcal{C} \) are described by a 3-supercocycle [GWW10] \( \tilde{F} : G^3 \to k^\times \) satisfying

\[
\tilde{F}(g, h, k)\tilde{F}(g, hk, l)\tilde{F}(h, k, l) = (-1)^{\omega(g, h)\omega(k, l)}\tilde{F}(gh, k, l)\tilde{F}(g, h, kl)
\]

where \( \omega \in H^2(G, \mathbb{Z}/2\mathbb{Z}) \) is a 2-cocycle on \( G \). In this situation, our formula for the \( 6j \)-\textit{symbols} on the underlying fusion category gives a 3-cocycle on the \( \mathbb{Z}/2\mathbb{Z} \)-central extension of \( G \) determined by \( \omega \), whose restriction to \( G \) is \( \tilde{F} \). In particular, this implies that every 3-supercocycle on \( G \) arises as the restriction of a (genuine) 3-cocycle on a central extension of \( G \) by \( \mathbb{Z}/2\mathbb{Z} \).

We also define the \( \pi \)-\textit{Grothendieck ring} \( s\text{Gr}(\mathcal{C}) \) of a superfusion category \( \mathcal{C} \), which is an algebra over \( \mathbb{Z}^\pi := \mathbb{Z}[\pi]/(\pi^2 - 1) \), and describe the relation between the \( \pi \)-Grothendieck ring of \( \mathcal{C} \) and the Grothendieck ring of the underlying fusion category \( \mathcal{C}_\pi^+ \). As a corollary of this, we deduce a version of Ocneanu rigidity for superfusion categories.

## 2. Fusion categories

Let \( k \) denote an algebraically closed field of characteristic 0.

**Definition 2.1** [ENO02]. A \textit{fusion category} over \( k \) is a semisimple rigid \( k \)-linear monoidal category \( \mathcal{A} \) with finitely many isomorphism classes of simple objects and finite-dimensional spaces of morphisms such that the unit object is simple.
In this section, we recall how the associator

\[ a : (- \otimes -) \otimes - \xrightarrow{\sim} - \otimes (- \otimes -). \]

in a fusion category can be described in terms of 6j-symbols, closely following the discussion in [Wan10, Chapter 4], see also [Tur94, Chapter VI].

**Example 2.2.** The category Vec of finite-dimensional k-vector spaces is a fusion category. More generally, if \( G \) is a finite group and \( \tau \in H^3(G, k^\times) \) is a 3-cocycle, then the category \( \text{Vec}_G \) of \( G \)-graded finite dimensional k-vector spaces with associativity defined by \( \tau \) is a fusion category.

### 2.1. 6j-Symbols.

Let \( A \) be a fusion category, and \( X_i, \ i \in I \) representatives of the isomorphism classes of simple objects in \( A \). The monoidal structure on \( A \) determines the fusion rules

\[ X_i \otimes X_j \simeq \bigoplus_{m \in I} N_{ij}^m X_m \]

where

\[ N_{ij}^m = \dim \text{Hom}_A(X_m, X_i \otimes X_j) = \dim \text{Hom}_A(X_i \otimes X_j, X_m) \in \mathbb{Z}_{\geq 0}. \]

is the multiplicity of \( X_m \) in \( X_i \otimes X_j \). The notion of admissibility will be useful.

**Definition 2.3** (see [Wan10, Definition 4.1]). Let \( A \) be a fusion category with simple objects indexed by a set \( I \). We say a triple \((i,j,m)\) is admissible if \( N_{ij}^m > 0 \). A quadruple \((i,j,m,\alpha)\) is admissible if \((i,j,m)\) is admissible, and \(1 \leq \alpha \leq N_{ij}^m\). A decuple \((i,j,m,k,n,t,\alpha,\beta,\eta,\varphi)\) is admissible if each of the quadruples \((i,j,m,\alpha),(m,k,n,\beta),(j,k,t,\eta)\) and \((i,t,n,\varphi)\) are admissible.

**Remark 2.4.** A fusion category is called multiplicity-free if \( N_{ij}^m \in \{0,1\} \) for all \( i,j,m \in I \) [Wan10, Definition 4.5]. In the multiplicity-free case, an admissible decuple is completely described by the sextuple \((i,j,m,k,n,t)\), in which case this definition recovers [Wan10, Definition 4.7].

That the triple \((i,j,m)\) is admissible is equivalent to saying that \( X_m \) is a direct summand of \( X_i \otimes X_j \). For each admissible triple \((i,j,m)\), choose a basis for the space \( \text{Hom}_A(X_i \otimes X_j, X_m) \). Admissible quadruples of the form \((i,j,m,\alpha)\) then label the basis vectors of \( \text{Hom}_A(X_i \otimes X_j, X_m) \). We denote these basis vectors by \( e_{ij}^m(\alpha) \), where \( 1 \leq \alpha \leq N_{ij}^m \).

We wish to describe the associator \( a(X_i, X_j, X_k) : (X_i \otimes X_j) \otimes X_k \rightarrow X_i \otimes (X_j \otimes X_k) \) in terms of our chosen basis. Indeed, fixing admissible quadruples \((i,j,m,\alpha)\) and \((m,k,n,\beta)\), we have the composition

\[ (X_i \otimes X_j) \otimes X_k \xrightarrow{e_{ij}^m(\alpha) \otimes \text{id}_{X_k}} X_m \otimes X_k \xrightarrow{e_{m}^n(\beta)} X_n \]

which we may represent graphically as
Let $t \in I$. If $(j, k, t, \eta)$ and $(i, t, n, \varphi)$ are admissible, then we have the composition

$$ (2) \quad (X_i \otimes X_j) \otimes X_k \xrightarrow{a(X_i, X_j, X_k)} X_i \otimes (X_j \otimes X_k) \xrightarrow{id_{X_i} \otimes e_{it}^j(\eta)} X_i \otimes X_t \xrightarrow{e_{it}^j(\varphi)} X_n $$

which we may represent graphically as

![Graphical representation of the composition](image)

Fix $i, j, k, n \in I$. Taking the direct sum of the above compositions over all $t \in I$ such that $(j, k, t, \eta)$ and $(i, t, n, \varphi)$ are admissible gives an isomorphism \cite[Lemma 1.1.1, Lemma 1.1.2]{Tur94}

$$ \bigoplus_{t \in I} \text{Hom}_A(X_j \otimes X_k, X_t) \otimes \text{Hom}_A(X_t \otimes X_n, X_n) \xrightarrow{\sim} \text{Hom}_A((X_i \otimes X_j) \otimes X_k, X_n) \xrightarrow{e_{it}^j(\eta) \otimes e_{it}^n(\varphi)} \text{Hom}_A((X_i \otimes X_j) \otimes X_k, X_n) $$

Expressing (1) in terms of this basis determines a constant $F_{ijm,\alpha\beta}^{knt,\eta\varphi} \in k$ for each admissible decuple $(i, j, m, k, n, t, \alpha, \beta, \eta, \varphi)$ in $A$, defined by the graphical equation:

![Graphical representation of the sum](image)

This describes the associator in $A$ as a collection of matrices $F_{knt}^{ijm,\alpha\beta} : \text{Hom}_A(X_i \otimes X_j, X_m) \otimes \text{Hom}_A(X_m \otimes X_k, X_n) \to \text{Hom}_A(X_j \otimes X_k, X_t) \otimes \text{Hom}_A(X_i \otimes X_t, X_n)$ whose entries are the constants defined above. The matrices $F_{knt}^{ijm,\alpha\beta}$ are called $6j$-symbols, as they depend on six indices. If $(i, j, m, k, n, t, \alpha, \beta, \eta, \varphi)$ is not admissible, then by convention we set $F_{knt}^{ijm,\alpha\beta} = 0$. The pentagon axiom in $A$ is then equivalent to the following equation in terms of $6j$-symbols.
Lemma 2.5 (Pentagon equation). Let $\mathcal{A}$ be a fusion category with simple objects indexed by a set $I$. If $i,j,k,l,m,n,t,p,q,s \in I$ and $\alpha, \beta, \eta, \chi, \gamma, \delta, \phi \in \mathbb{Z}_{\geq 0}$. Then

$$\sum_{t \in I} \sum_{\eta=1}^{N_t} \sum_{\varphi=1}^{N_{\eta t}} \sum_{\kappa=1}^{N_{\eta \kappa}} F_{ijm, \alpha \beta}^{\eta t n, \varphi \chi} F_{knt, \eta \kappa}^{\varphi \chi lps, \delta \gamma} F_{ikt, \eta \kappa}^{\varphi \chi lsq, \delta \phi} = \sum_{c=1}^{N_{mq}} \sum_{\epsilon=1}^{N_{p}} F_{mkn, \beta \chi}^{\eta \kappa l, \delta \epsilon} F_{ijm, \alpha \epsilon}^{\eta \kappa qps, \delta \gamma}$$

(3)

Example 2.6 (see Example 2.3.8 [EGNO15]). Continuing Example 2.2, the fusion category $\text{Vec}_G$ has pairwise non-isomorphic simple objects $\{\delta_g\}_{g \in G}$ satisfying $\delta_g \otimes \delta_h \cong \delta_{gh}$, so admissible quadruples are of the form $(g, h, gh, 1)$ for all $g, h \in G$. Thus given $g, h, k \in G$ we can write $F(g, h, k) := F^g_{h, k} \in \mathbb{k}^\times$ for the corresponding 6j-symbol unambiguously. The pentagon equation (3) then reduces to

$$F(g, h, k)F(g, hk, l)F(h, k, l) = F(gh, k, l)F(g, h, kl) \quad g, h, k, l \in G$$

so $F$ is a 3-cocycle on $G$ with values in $\mathbb{k}^\times$.

3. Superfusion categories

In this section we recall the definition of a superfusion category using the language of [BE16], and describe the associator in a superfusion category in terms of fermionic 6j-symbols, following [GK15]. By a superspace we always mean a $\mathbb{Z}/2\mathbb{Z}$-graded $\mathbb{k}$-vector space $V$. The parity of a homogeneous element $v \in V$ will be denoted by $|v|$.

Definition 3.1. Let $\text{sVect}$ be the category whose objects are superspaces, and whose morphisms are even linear maps, i.e. linear maps preserving the grading.

We can make $\text{sVect}$ into a monoidal category by defining the tensor product of superspaces $V$ and $W$ to be the superspace $V \otimes W$ with $(V \otimes W)_0 := (V_0 \otimes W_0) \oplus (V_1 \otimes W_1)$ and $(V \otimes W)_1 := (V_1 \otimes W_0) \oplus (V_0 \otimes W_1)$, with the tensor product of morphisms defined in the obvious way. The braiding

$$c_{V,W}(v \otimes w) = (-1)^{|v||w|} v \otimes w$$

defined on homogeneous $v \in V$ and $w \in W$ makes $\text{sVect}$ into a symmetric monoidal category.

Definition 3.2 (see [BE16] Definition 1.1 and [Kel05] Section 1.2 for details). A supercategory is a $\text{sVect}$-enriched category. A superfunctor between supercategories is a $\text{sVect}$-enriched functor, and a supernatural transformation between superfunctors is a $\text{sVect}$-enriched supernatural transformation. We say a supernatural transformation is even if all its component maps are even.

In particular, if $\mathcal{A}$ is a supercategory, then $\text{Hom}_\mathcal{A}(X, Y)$ is a superspace for all $X, Y \in \mathcal{A}$, and composition

$$\text{Hom}_\mathcal{A}(Z, Y) \otimes \text{Hom}_\mathcal{A}(X, Y) \to \text{Hom}_\mathcal{A}(X, Z)$$

is an even linear map for all $X, Y, Z \in \mathcal{A}$.
Remark 3.3. Given supercategories $\mathcal{A}$ and $\mathcal{B}$, we can form their tensor product $\mathcal{A} \boxtimes \mathcal{B}$. Objects of $\mathcal{A} \boxtimes \mathcal{B}$ are pairs $(X, Y)$ with $X \in \mathcal{A}$ and $Y \in \mathcal{B}$. Morphisms in $\mathcal{A} \boxtimes \mathcal{B}$ are given by $\text{Hom}_{\mathcal{A} \boxtimes \mathcal{B}}((X, Y), (W, Z)) := \text{Hom}_\mathcal{A}(X, W) \otimes \text{Hom}_\mathcal{B}(Y, Z)$, with composition in $\mathcal{A} \boxtimes \mathcal{B}$ defined using the braiding in sVect, see [BE16] for details.

Definition 3.4 ([BE16 Definition 1.4]). A monoidal supercategory is a supercategory $\mathcal{D}$, together with a tensor product superfunctor $\otimes : \mathcal{D} \times \mathcal{D} \to \mathcal{D}$, a unit object $1$, and even supernatural isomorphisms $a : (- \otimes -) \otimes - \to - \otimes (- \otimes -)$, $l : 1 \otimes - \to -$ and $r : - \otimes 1 \to -$ satisfying axioms analogous to the ones of a monoidal category. A monoidal superfunctor between monoidal supercategories $\mathcal{D}$ and $\mathcal{E}$ is a superfunctor $F : \mathcal{D} \to \mathcal{E}$ such that $F(1_\mathcal{D})$ is evenly isomorphic to $1_\mathcal{E}$, together with even coherence maps $J : F(-) \otimes F(-) \to F(- \otimes -)$ satisfying the usual axioms.

An important feature of monoidal supercategories is the super interchange law

$$(f \otimes g) \circ (h \otimes k) = (-1)^{|g||h|}(f \circ h) \otimes (g \circ k)$$

describing the composition of tensor products of morphisms. We recall the following definitions from [GWW10] Appendix C.

Definition 3.5. A superfusion category over $k$ is a semisimple rigid monoidal supercategory $\mathcal{C}$ with finitely many simple objects and finite dimensional superspaces of morphisms such that the unit object $1$ is simple. A simple object $X \in \mathcal{C}$ is Bosonic if $\text{Hom}_\mathcal{C}(X, X) \simeq k^{1|0}$, and Majorana if $\text{End}_\mathcal{C}(X) \simeq k^{1|1}$. A superfusion category is called Bosonic if all its simple objects are Bosonic.

The unit object $1$ in a superfusion category $\mathcal{C}$ is always Bosonic. Indeed, since $1 \otimes 1 \simeq 1$, the tensor product functor induces an embedding

$$\text{Hom}_\mathcal{C}(1, 1) \otimes \text{Hom}_\mathcal{C}(1, 1) \to \text{Hom}_\mathcal{C}(1 \otimes 1, 1 \otimes 1) \simeq \text{Hom}_\mathcal{C}(1, 1)$$

which implies $\text{Hom}_\mathcal{C}(1, 1) \simeq k^{1|0}$.

Remark 3.6. That $\mathcal{C}$ is rigid means that for each $X \in \mathcal{C}$ we have a left dual $X^* \in \mathcal{C}$ and a right dual $^*X \in \mathcal{C}$, together with even morphisms $\text{ev}_X : X^* \otimes X \to 1$, $\text{coev}_X : 1 \to X \otimes X^*$, $\text{ev}'_X : X \otimes ^*X \to 1$, and $\text{coev}'_X : 1 \to ^*X \otimes X$ satisfying the usual equations, see [EGNO15] Section 2.10] for details.

3.1. Fermionic 6j-symbols. Let $\mathcal{C}$ be a superfusion category, and $X_i$, $i \in I$ representatives of the isomorphism classes of simple objects in $\mathcal{C}$. The monoidal structure on $\mathcal{C}$ determines the superfusion rules

$$X_i \otimes X_j \simeq \bigoplus_{m \in I} N_{ij}^m X_m$$

where

$$N_{ij}^m = \dim \text{Hom}_\mathcal{C}(X_i \otimes X_j, X_m) = \dim \text{Hom}_\mathcal{C}(X_m, X_i \otimes X_j) \in \mathbb{Z}_{\geq 0}$$

i.e. $N_{ij}^m$ is the dimension of the superspace $\text{Hom}_\mathcal{C}(X_i \otimes X_j, X_m)$. With this notation, our notion of admissible triple, quadruple, and decuple remain the same.
FERMIONIC 6J-SYMBOLS IN SUPERFUSSION CATEGORIES

as in Definition 2.3. As in the fusion category case, for each admissable triple \((i, j, m)\) we choose a homogeneous basis for the superspace \(\text{Hom}_C(X_i \otimes X_j, X_m)\) denoted by \(e_m^{ij}(\alpha)\), where \(1 \leq \alpha \leq N_m^{ij}\). Let \(s_m^{ij}(\alpha) = |e_m^{ij}(\alpha)|\) denote the parity of the corresponding basis vector.

**Definition 3.7.** We say that an admissable decuple \((i, j, m, k, n, t, \alpha, \beta, \eta, \varphi)\) is parity admissable if

\[
s_m^{ij}(\alpha) + s_n^{mk}(\beta) = s_t^{jk}(\eta) + s_t^{it}(\varphi).
\]

In exactly the same way as in the fusion category case, we define constants \(\hat{F}_{ijm, \alpha \beta}^{knt, \eta \varphi} \in k\) for each admissable decuple \((i, j, m, k, n, t, \alpha, \beta, \eta, \varphi)\) in \(C\), defined by the graphical equation

\[
\begin{array}{c}
\includegraphics{figure.png}
\end{array} = \sum_{t \in I} \sum_{\eta = 1}^{N_t^{sk}} \sum_{\phi = 1}^{N_t^{st}} \hat{F}_{ijm, \alpha \beta}^{knt, \eta \varphi}
\]

**Remark 3.8.** We recover the parity admissability condition (4) by comparing the parity of both sides of the above equation. In particular, the constant \(\hat{F}_{ijm, \alpha \beta}^{knt, \eta \varphi}\) is non-zero only for parity admissable decuples \((i, j, m, k, n, t, \alpha, \beta, \eta, \varphi)\).

This describes the associativity constraint in \(C\) as a collection of invertible matrices

\[
\hat{F}_{ijm}^{knt} : \text{Hom}_C(X_i \otimes X_j, X_m) \otimes \text{Hom}_C(X_m \otimes X_k, X_n) \to \text{Hom}_C(X_j \otimes X_k, X_t) \otimes \text{Hom}_C(X_i \otimes X_t, X_n)
\]

whose entries are the constants defined above. The matrices \(\hat{F}_{ijm}^{knt}\) are called fermionic 6j-symbols. If \((i, j, m, k, n, t, \alpha, \beta, \eta, \varphi)\) is not (parity) admissable, then by convention we set \(\hat{F}_{ijm, \alpha \beta}^{knt, \eta \varphi} = 0\). The super pentagon axiom in \(C\) is equivalent to the following equation in terms of fermionic 6j-symbols, called the fermionic pentagon identity in [GWW10].

**Lemma 3.9 (Super pentagon equation).** Let \(C\) be a superfusion category with simple objects indexed by a set \(I\). If \(i, j, k, l, m, n, t, p, q, s \in I\) and \(\alpha, \beta, \eta, \chi, \gamma, \delta, \phi \in \mathbb{Z}_{\geq 0}\), then

\[
(5) \quad \sum_{t \in I} \sum_{\eta = 1}^{N_t^{sk}} \sum_{\phi = 1}^{N_t^{st}} \hat{F}_{ijm, \alpha \beta}^{knt, \eta \varphi} \hat{F}_{nxp, \chi \gamma}^{lpq, \delta \phi} \hat{F}_{jkt, \eta \kappa}^{lps, \delta \alpha} = (-1)^{s_m^{ij}(\alpha) s_t^{kl}(\beta)} \sum_{\epsilon = 1}^{N_{pq}^{st}} \hat{F}_{mkn, \beta \chi}^{lpq, \delta \epsilon} \hat{F}_{ijm, \alpha \epsilon}^{knt, \eta \gamma}
\]

**Example 3.10.** We say a superfusion category \(C\) is pointed if any simple object \(X \in C\) is invertible, that is, there exists \(Y \in C\) such that \(X \otimes Y \simeq Y \otimes X \simeq 1\). Let \(C\) be a Bosonic superfusion category, and let \(G\) be the (finite) group of isomorphism classes of simple objects in \(C\), and choose \(X_g, g \in G\) a set of representatives of simple objects in \(C\). Then \(X_g \otimes X_h \simeq X_{gh}\) for all \(g, h \in G\), so admissible
quadruples in $C$ are of the form $(g, h, gh, 1)$ for all $g, h \in G$. Let $\omega(g, h)$ denote the parity of the one-dimensional superspace $\text{Hom}_C(X_g \otimes X_h, X_{gh})$, then the parity admissibility condition (4) implies

$$\omega(g, h) + \omega(gh, k) = \omega(h, k) + \omega(g, hk).$$

for all $g, h, k \in G$, so $\omega$ is a 2-cocycle on $G$ with values in $\mathbb{Z}/2\mathbb{Z}$. The super pentagon equation (5) implies

$$\tilde{F}(g, h, k)\tilde{F}(g, hk, l)\tilde{F}(h, k, l) = (-1)^{\omega(g,h)\omega(k,l)}\tilde{F}(gh, k, l)\tilde{F}(g, h, kl)$$

for all $g, h, k, l \in G$, so following [GWW10] we say $\tilde{F}$ is a $3$-supercocycle on $G$.

4. Fusion categories over sVect

In this section, we show that every superfusion category is equivalent to a $\Pi$-complete superfusion category (i.e. a superfusion category equipped with an odd isomorphism $\zeta: \pi \sim \rightarrow 1$), and give the construction of the underlying fusion category of a $\Pi$-complete superfusion category, following [BE16].

Recall that a fusion category is braided if it is equipped with a natural isomorphism $c_{X,Y}: X \otimes Y \sim Y \otimes X$ satisfying well-known axioms, see [JS93, Definition 2.1], [EGNO15, Definition 8.1.1]. A monoidal functor between braided fusion categories is braided if it respects the braiding, see [JS93, Definition 2.3], [EGNO15, Definition 8.1.7].

**Definition 4.1** ([EGNO15, Definition 7.13.1]). The centre of a fusion category $A$ is the category $Z(A)$ whose objects are pairs $(Z, \beta)$ where $Z \in A$ and

$$\beta_X: X \otimes Z \sim Z \otimes X, \ X \in A$$

is a natural isomorphism such that the following diagram

$$
\begin{align*}
X \otimes (Z \otimes Y) & \xrightarrow{a(X, Z, Y)^{-1}} (X \otimes Z) \otimes Y \\
X \otimes (Y \otimes Z) & \xrightarrow{a(X, Y, Z)^{-1}} (X \otimes Y) \otimes Z \\
(Z \otimes X) \otimes Y & \xrightarrow{\beta_X \otimes id_Y} Z \otimes (X \otimes Y)
\end{align*}
$$

is commutative for all $X, Y \in A$.

A morphism from $(Z, \beta)$ to $(Z', \beta')$ is a morphism $f \in \text{Hom}_A(Z, Z')$ such that

$$(f \otimes \text{id}_X) \circ \beta_X = \beta'_X \circ (\text{id}_X \otimes f)$$

for all $X \in A$.

Equipping $Z(A)$ with the usual tensor product (see [EGNO15, Definition 7.13.1]) and braiding $c_{(Z, \beta), (Z', \beta')}: \beta'_Z$ makes $Z(A)$ into a braided fusion category, see [EGNO15, Proposition 8.5.1 and Theorem 9.3.2].
Definition 4.2 ([DGNO10 Definition 4.16]). A fusion category over $s\text{Vect}$ is a fusion category $\mathcal{A}$ equipped with a braided functor $s\text{Vect} \to \mathcal{Z}(\mathcal{A})$. Equivalently, this is an object $(\pi, \beta)$ in the centre $\mathcal{Z}(\mathcal{A})$ together with an even isomorphism $\xi : \pi \otimes \pi \sim 1$ such that

\begin{equation}
(\xi^{-1} \otimes \text{id}_X) \circ l_X^{-1} \circ r_X \circ (\text{id}_X \otimes \xi) = a(\pi, \pi, X)^{-1} \circ (\text{id}_\pi \otimes \beta_X) \circ a(\pi, X, \pi) \circ (\beta_X \otimes \text{id}_\pi) \circ a(X, \pi, \pi)^{-1}
\end{equation}

for all $X \in \mathcal{A}$, and

\begin{equation}
\beta_\pi = -\text{id}_{\pi \otimes \pi} \in \text{Hom}_A(\pi \otimes \pi, \pi \otimes \pi).
\end{equation}

In this situation we say $(\mathcal{A}, \pi, \beta, \xi)$ is a fusion category over $s\text{Vect}$.

Remark 4.3. In this section, we will often draw commutative diagrams with associativity and unit isomorphisms omitted, unless confusion is possible. For example, we represent Equation (6) as the diagram

In addition we say that the diagram

\begin{equation}
X \xrightarrow{g} Y \xrightarrow{k} Y' \xrightarrow{h} Z
\end{equation}

is supercommutative if $h \circ k = -f \circ g$.

4.1. The $\Pi$-envelope of a superfusion category.

Definition 4.4. Let $\mathcal{C}$ be a superfusion category, together with an object $\pi$ and an odd isomorphism $\zeta : \pi \sim 1$. In this situation, we say that $(\mathcal{C}, \pi, \zeta)$ is a $\Pi$-complete superfusion category.

In particular, this implies that every object in $\mathcal{C}$ is the target of an odd isomorphism. It turns out that every superfusion category is equivalent to a $\Pi$-complete superfusion category, by the following construction described in [BE16].

Definition 4.5 (see [BE16 Definition 1.16]). Let $\mathcal{C}$ be a superfusion category. The $\Pi$-envelope of $\mathcal{C}$ is the rigid monoidal supercategory $\mathcal{C}_\pi$ with objects of the form $X^a$, where $X \in \mathcal{C}$ and $a \in \mathbb{Z}/2\mathbb{Z}$, and morphisms defined by

\[
\text{Hom}_{\mathcal{C}_\pi}(X^a, Y^b)_c := \text{Hom}_\mathcal{C}(X, Y)^{a+b+c}
\]
If \( f : X \to Y \) is a homogeneous morphism in \( C \) with parity \(|f|\), then let \( f^b_a \) denote the corresponding morphism \( X^a \to Y^b \) which has parity \( a + b + |f| \) in \( C_\pi \). The composition in \( C_\pi \) is induced by the composition in \( C \), and the tensor proper of objects and morphisms is defined by

\[
X^a \otimes Y^b := (X \otimes Y)^{a+b}
\]

\[
f^b_a \otimes g^d_c := (-1)^{(a+d+|g|)+d|f|}(f \otimes g)^{b+d+c}
\]

The unit object of \( C_\pi \) is \( 1^0_0 \), and the maps \( a, l, \) and \( r \) in \( C \) extend to \( C_\pi \) in the obvious way. The left dual of an object \( X^a \in C_\pi \) is given by \((X^*)^a \), where evaluation and coevaluation morphisms are given by

\[
ev_{X^a} := (ev^0_{X^a}) : (X^*)^a \otimes X^a \to 1^0_0
\]

\[
\text{coev}_{X^a} := (\text{coev}^0_{X^a}) : 1^0_0 \to X^a \otimes (X^*)^a
\]

Similarly, the right dual of \( X^a \in C_\pi \) is \((^*X)^a \in C_\pi \), where \( ev'_{X^a} := (ev'_{X}^0) \) and \( \text{coev}'_{X^a} := (\text{coev}'_{X}^0) \).

The functor \( J : C \to C_\pi \) sending \( X \mapsto X^0 \) and \( f \mapsto (f)^0_0 \) is full, faithful, and essentially surjective, so \( C \) and \( C_\pi \) are equivalent as superfusion categories. However \( J \) need not be a superequivalence in general, indeed, in [BE16, Lemma 4.1] it is shown that \( J \) is a superequivalence if and only if \( C \) is \( \Pi \)-complete.

**Definition 4.6.** The superadditive envelope \( C_\pi^+ \) of a superfusion category \( C \) is the superfusion category obtained by taking the additive envelope of the \( \Pi \)-envelope of \( C \).

In \( C_\pi^+ \) we have the odd isomorphism \( \zeta := (id_1)^0_0 : 1^1_1 \to 1^0_0 \), so \((C_\pi^+, 1^1_1, \zeta)\) is a \( \Pi \)-complete superfusion category.

### 4.2. The underlying fusion category of a \( \Pi \)-complete superfusion category.

**Definition 4.7.** Let \((\mathcal{L}, \pi, \zeta)\) be a \( \Pi \)-complete superfusion category. The underlying fusion category \( \mathcal{L} \) of \( \mathcal{L} \) is the fusion category with the same objects as \( \mathcal{L} \), but only the even morphisms.

Since \((\mathcal{L}, \pi, \zeta)\) is \( \Pi \)-complete, we can endow \( \mathcal{L} \) with the structure of a fusion category over \( s\text{Vect} \). Indeed, define the even supernatural transformation \( \beta : - \otimes \pi \sim \pi \otimes - \) by letting \( \beta_X \) be the composition

\[
X \otimes \pi \xrightarrow{id_X \otimes \zeta} X \otimes 1 \xrightarrow{r_X} X \xrightarrow{i_X^{-1}} 1 \otimes X \xrightarrow{\zeta^{-1} \otimes id_X} \pi \otimes X
\]

for \( X \in \mathcal{L} \). It is straightforward to check that \( \beta \) is an even supernatural transformation, and that \((\pi, \beta)\) is an object of the centre \( Z(\mathcal{L}) \) of \( \mathcal{L} \). Let \( \xi = l_1 \circ (\zeta \otimes \zeta) : \pi \otimes \pi \sim 1 \), then \( \xi \) is even and thus may be viewed as an isomorphism \( \pi \otimes \pi \sim 1 \) in \( \mathcal{L} \). The following lemma is a special case of [BE16, Lemma 3.2].
Lemma 4.8. \((\mathcal{L}, \pi, \beta, \xi)\) is a fusion category over \(\text{sVect}\).

Proof. We must show that equations (6) and (7) hold. For the former, observe that
\[\xi - 1 = - (\zeta^{-1} \otimes \zeta^{-1}) \circ l_1^{-1}\]
by the super interchange law, so it is enough to show that the following diagram
\[
\begin{array}{ccc}
X & \xrightarrow{\pi \otimes \pi \otimes X} & \pi \otimes X \\
\downarrow{\id_X \otimes \zeta} & & \downarrow{\id_X \otimes \zeta} \\
X \otimes \pi & \xrightarrow{\zeta^{-1} \otimes \id_X \otimes \id_X} & \pi \otimes X \otimes \pi
\end{array}
\]
is commutative. The super interchange law implies that the top (respectively left) triangle commutes (respectively supercommutes), while supernaturality of \(\zeta^{-1}\) implies the rectangle supercommutes, and so the diagram is commutative. For (7), consider the following diagram.
\[
\begin{array}{ccc}
\pi \otimes \pi & \xrightarrow{\id_\pi \otimes \zeta} & \pi \otimes 1 \\
\downarrow{\zeta \otimes \id_\pi} & & \downarrow{\zeta \otimes \id_\pi} \\
\pi \otimes \pi & \xrightarrow{\id_\pi \otimes \zeta} & \pi \otimes 1
\end{array}
\]
The first and last cell supercommute by the super interchange law, while the middle cells commute by naturality of \(l\) and \(r\). Thus
\[(\id_\pi \otimes \zeta) \circ \beta_\pi = [- (\zeta^{-1} \otimes \id_1)] \circ [- (\id_1 \otimes \zeta) \circ (\zeta \otimes \id_\pi)]\]
and so \(\beta_\pi = (\id_\pi \otimes \zeta^{-1}) \circ (\zeta^{-1} \otimes \id_1) \circ (\id_1 \otimes \zeta) \circ (\zeta \otimes \id_\pi) = - \id_\pi \otimes \pi\) by the super interchange law.

Thus to every \(\Pi\)-complete superfusion category there is a corresponding fusion category over \(\text{sVect}\). We now present the inverse construction, as given in [BE16, §5].

Definition 4.9. Let \((\mathcal{A}, \pi, \beta, \xi)\) be a fusion category over \(\text{sVect}\). The associated superfusion category \(\hat{\mathcal{A}}\) is the \(\Pi\)-complete superfusion category with the same objects as \(\mathcal{A}\), but with morphisms defined by
\[
\Hom_{\hat{\mathcal{A}}}(X, Y)_0 := \Hom_{\mathcal{A}}(X, Y) \quad \text{and} \quad \Hom_{\hat{\mathcal{A}}}(X, Y)_1 := \Hom_{\mathcal{A}}(X, \pi \otimes Y)
\]
Let \(f \in \Hom_{\hat{\mathcal{A}}}(X, Y)\) and \(g \in \Hom_{\hat{\mathcal{A}}}(Y, Z)\) be homogeneous morphisms in \(\mathcal{A}\), then their composition \(g \circ f\) in \(\hat{\mathcal{A}}\) is defined in the obvious way, except when \(f\) and \(g\) are both odd, in which case \(g \circ f\) is induced by the composition
\[
X \xrightarrow{f} \pi \otimes Y \xrightarrow{\id_\pi \otimes g} \pi \otimes (\pi \otimes Z) \xrightarrow{a_{\pi, \pi, Z}^{-1}} (\pi \otimes \pi) \otimes Z \xrightarrow{\xi \otimes \id_Z} 1 \otimes Z \xrightarrow{l_Z} Z.
\]
The tensor product of objects in \( \hat{A} \) is identical to that in \( A \). If \( f \in \text{Hom}_\hat{A}(W,Y) \), \( g \in \text{Hom}_\hat{A}(X,Z) \) are homogeneous morphisms, then their tensor product \( f \otimes g : W \otimes X \to Y \otimes Z \) is defined as follows:

- If \( f \) and \( g \) are both even, let \( f \otimes g := f \otimes g \).
- If \( f \) is even and \( g \) is odd, let \( f \otimes g := a(\pi,Y,Z) \circ (\beta_Y \otimes \text{id}_Z) \circ a(Y,\pi,Z)^{-1} \circ f \otimes g \).
- If \( f \) is odd and \( g \) is even, let \( f \otimes g := a(\pi,Y,Z) \circ (f \otimes g) \).
- If \( f \) and \( g \) are both odd, let \( f \otimes g \) be induced by the composition

\[
W \otimes X \xrightarrow{f \otimes g} \pi \otimes Y \otimes \pi \otimes Z \xrightarrow{id_\pi \otimes \beta_Y \otimes \text{id}_Z} \pi \otimes \pi \otimes Y \otimes Z \xrightarrow{\xi \otimes \text{id}_Y \otimes Z} Y \otimes Z
\]

where we have suppressed associativity and unit isomorphisms for brevity.

One can check on a case by case basis that the composition defined in \( \hat{A} \) is associative. The most interesting case is when \( f \in \text{Hom}_\hat{A}(W,Y)_1 \), \( g \in \text{Hom}_\hat{A}(X,Y)_1 \) and \( h \in \text{Hom}_\hat{A}(Y,Z)_1 \) are homogeneous odd morphisms. In this case, it suffices to show that the following diagram

\[
\begin{array}{c}
\pi \otimes (\pi \otimes Y) \xrightarrow{\alpha^{-1}} (\pi \otimes \pi) \otimes Y \xrightarrow{\xi \otimes \text{id}} 1 \otimes Y \xrightarrow{l_Y} Y \\
\pi \otimes (\pi \otimes (\pi \otimes Z)) \xrightarrow{\alpha^{-1}} (\pi \otimes \pi) \otimes (\pi \otimes Z) \xrightarrow{\xi \otimes \text{id}} 1 \otimes (\pi \otimes Z) \\
\pi \otimes ((\pi \otimes \pi) \otimes Z) \xrightarrow{\alpha^{-1}} (\pi \otimes (\pi \otimes \pi)) \otimes Z \xrightarrow{\xi \otimes \text{id}} 1 \otimes (\pi \otimes Z) \\
\pi \otimes (1 \otimes Z) \xrightarrow{\alpha^{-1}} (\pi \otimes 1) \otimes Z \xrightarrow{\alpha^{-1}} 1 \otimes (\pi \otimes Z) \\
\end{array}
\]

is commutative. To see this, observe that \( \beta_{\pi \otimes \pi} = a(\pi,\pi,\pi) \) by Equation [7], and so the 5-sided cell commutes by the pentagon axiom. In addition, we have used that \( r_\pi \circ \beta_1 = l_\pi \) for commutativity of the bottom right triangle. All other cells commute by naturality or the triangle axiom.

It is a similar exercise to check that the tensor product defined in \( \hat{A} \) satisfies the super interchange law. As before, the most interesting case is when \( f \in \text{Hom}_\hat{A}(W,Y)_1 \), \( g \in \text{Hom}_\hat{A}(X,Z)_1 \), \( h \in \text{Hom}_\hat{A}(A,W)_1 \), and \( k \in \text{Hom}_\hat{A}(B,X)_1 \) are odd homogeneous morphisms, in which case we must show that \((f \otimes g) \circ (h \otimes k) = -(f \otimes h) \circ (g \otimes k)\). This reduces to showing that the following diagram
is supercommutative. The top cell commutes by naturality of $\beta$, while the right cell commutes by naturality of $-\xi$. Since $(\pi, \beta)$ is in the centre $Z(A)$, the diagram

\[
\begin{array}{ccc}
A \otimes B & h \otimes k & \pi \otimes W \otimes \pi \otimes X \\
\downarrow \text{id} \otimes f \otimes \text{id} \otimes g & & \downarrow \text{id} \otimes f \otimes g \\
\pi \otimes \pi \otimes Y \otimes \pi \otimes \pi \otimes Z & \text{id} \otimes \beta_Y \otimes \text{id} & \pi \otimes \pi \otimes \pi \otimes Y \otimes \pi \otimes Z \\
\downarrow \xi \otimes \text{id} & & \downarrow -\xi \otimes \text{id} \\
Y \otimes \pi \otimes \pi \otimes Z & \beta_Y \otimes \text{id} & \pi \otimes Y \otimes \pi \otimes Z \\
\downarrow \text{id} \otimes \xi \otimes \text{id} & & \downarrow \text{id} \otimes \beta_Y \otimes \text{id} \\
Y \otimes Z & & \pi \otimes \pi \otimes Y \otimes Z \\
\end{array}
\]

is commutative. Recalling that $\beta_\pi = -\text{id}_{\pi \otimes \pi}$, we get that the middle cell commutes by naturality of $\beta$. The bottom cell supercommutes by comparison with Equation (6).

**Lemma 4.10** ([BE16, Lemma 5.4]). Let $(\mathcal{L}, \pi, \zeta)$ be a $\Pi$-complete superfusion category, and define

\[G : \hat{\mathcal{L}} \rightarrow \mathcal{L} \]

\[X \mapsto X \]

\[f \in \text{Hom}_{\hat{\mathcal{L}}}(X,Y) \mapsto \begin{cases} f \in \text{Hom}_\mathcal{L}(X,Y)_0 & \text{if } f \text{ even} \\ l_Y \circ (\zeta \otimes \text{id}_Y) \circ f \in \text{Hom}_\mathcal{L}(X,Y)_1 & \text{if } f \text{ odd} \end{cases} \]

where $f$ is a homogeneous morphism. Then $G$ is an isomorphism of superfusion categories.

**Proof.** Observe that $G$ is a bijection on objects and morphisms, so it remains to show that $G$ respects composition and the tensor product. Let $f \in \text{Hom}_{\hat{\mathcal{L}}}(X,Y)$ and $g \in \text{Hom}_{\hat{\mathcal{L}}}(Y,Z)$ be homogeneous morphisms in $\mathcal{L}$. We only consider the most interesting case when $f$ and $g$ are both odd. In this case, $G(g) \circ G(f)$ is given by the composition

\[X \xrightarrow{f} \pi \otimes Y \xrightarrow{\zeta \otimes \text{id}_Y} 1 \otimes Y \xrightarrow{l_Y} Y \xrightarrow{g} \pi \otimes Z \xrightarrow{\zeta \otimes \text{id}_Z} 1 \otimes Z \xrightarrow{l_Z} Z \]
while $G(g \circ f)$ is given by the composition

$$X \xrightarrow{f} \pi \otimes Y \xrightarrow{id_{\pi} \otimes g} \pi \otimes (\pi \otimes Z) \xrightarrow{\alpha(\pi, \pi, Z)^{-1}} (\pi \otimes \pi) \otimes Z \xrightarrow{\zeta \otimes id_Z} 1 \otimes id_{Z} \xrightarrow{id_{Z}} Z$$

and we must show these are equal. Indeed, $g \circ l_Y \circ (\zeta \otimes id_Y) = -l_{\pi \otimes Z} \circ (\zeta \otimes id_{\pi \otimes Z}) \circ (id_{\pi} \otimes g)$ by supernaturality, and so it remains to show that the following diagram

$$
\begin{array}{c}
\pi \otimes Y \xrightarrow{\zeta \otimes id_Y} 1 \otimes Y \\
\downarrow{id_{\pi} \otimes g} \quad \downarrow{id_{1} \otimes g} \\
\pi \otimes (\pi \otimes Z) \xrightarrow{\zeta \otimes id_{\pi \otimes Z}} 1 \otimes (\pi \otimes Z) \xrightarrow{l_{\pi \otimes Z}} \pi \otimes Z \\
\downarrow{a(\pi, \pi, Z)^{-1}} \quad \downarrow{l_{\pi} \otimes id_{Z}} \\
(\pi \otimes \pi) \otimes Z \xrightarrow{\zeta \otimes id_{\pi} \otimes id_{Z}} (1 \otimes \pi) \otimes Z \xrightarrow{-1 \otimes id} (1 \otimes 1) \otimes Z
\end{array}
$$

is commutative, where we have used that $\xi = -l_{1} \circ (id_{1} \otimes \zeta) \circ (\zeta \otimes id_{\pi})$. The top left cell supercommutes by supernaturality of $\zeta$, the top right cell commutes by naturality of $l$, the bottom left cell commutes by naturality of $a$, the bottom triangle commutes by the triangle axiom, and the bottom right cell supercommutes by naturality of $\zeta$. Thus $G(g \circ f) = G(g) \circ G(f)$.

Similarly, one can check that if $f \in \text{Hom}_{\mathfrak{L}}(W, Y)$ and $g \in \text{Hom}_{\mathfrak{L}}(X, Z)$ then $G(f \circ g) = G(f) \otimes G(g)$. As before, we only consider the case where $f$ and $g$ are homogeneous odd morphisms. In this case, we have

$$G(f) \otimes G(g) = (l_{Y} \circ (\zeta \otimes id_{Y}) \circ f) \otimes (l_{Z} \circ (\zeta \otimes id_{Z}) \circ g) = -(l_{Y} \otimes l_{Z}) \circ ((\zeta \otimes id_{Y}) \otimes (\zeta \otimes id_{Z})) \circ (f \otimes g)$$

by the super interchange law. By comparing this with the definition of $G(f \circ g)$, it suffices to show that the following diagram

$$
\begin{array}{c}
\pi \otimes Y \otimes \pi \otimes Z \xrightarrow{-\zeta \otimes id_{\pi} \otimes id_{Z}} Y \otimes Z \\
\downarrow{id_{\pi} \otimes \zeta \otimes id} \quad \downarrow{\zeta \otimes id} \\
\pi \otimes Y \otimes Z \xrightarrow{id_{\pi} \otimes \zeta^{-1} \otimes id} \pi \otimes Y \otimes Z
\end{array}
$$

is commutative, where we have again used that $-\xi = l_{1} \circ (id_{1} \otimes \zeta) \circ (\zeta \otimes id_{\pi})$. The top triangle supercommutes by the super interchange law, while the bottom cell supercommutes by supernaturality of $\zeta$, and so $G(f \circ g) = G(f) \otimes G(g)$. 

Thus every II-complete superfusion category can be obtained from a fusion category over $s\text{Vect}$ by the above construction. In fact, it is shown in [BE16] that the functor $G$ described above forms part of an equivalence between the category of fusion categories over $s\text{Vect}$ and the category of II-complete superfusion categories.
Definition 5.1. Let \( \mathcal{C} \) be a superfusion category, and let \( \mathcal{C}^+_\pi \) be the underlying fusion category of the superadditive envelope of \( \mathcal{C} \) (see Definition 4.5 and Definition 4.6). We call \( \mathcal{C}^+_\pi \) the underlying fusion category of \( \mathcal{C} \).

In this section, we give an explicit formula for the 6j-symbols of \( \mathcal{C}^+_\pi \) in terms of the fermionic 6j-symbols of \( \mathcal{C} \). Recall that for \( X, Y \in \mathcal{C} \) and \( a, b \in \mathbb{Z}/2\mathbb{Z} \), we have

\[
\text{Hom}_{\mathcal{C}^+_\pi}(X^a, Y^b) = \text{Hom}_\mathcal{C}(X, Y)^{a+b}
\]

If \( f: X \to Y \) is a homogeneous morphism in \( \mathcal{C} \) and \( a + b = |f| \), then we denote by \( f^b_a \) the corresponding morphism \( X^a \to Y^b \) in \( \mathcal{C}^+_\pi \). The tensor product of objects and morphisms in \( \mathcal{C}^+_\pi \) is defined by

\[
X^a \otimes Y^b := (X \otimes Y)^{a+b}
\]

\[
f^b_a \otimes g^d_c := (-1)^{|f||g|} (f \otimes g)^{b+d}_{a+c}
\]

From Lemma 4.8 we get that \( (\mathcal{C}^+_\pi, 1^1, \beta, \xi) \) is a fusion category over s\text{Vect}, where

\[
\beta_{X^a} = (-1)^a \cdot (l_X^{-1} \circ r_X)^{a+1}_{a+1} : X^a \otimes 1^1 \xrightarrow{\sim} 1^1 \otimes X^a, \ X^a \in \mathcal{C}^+_\pi
\]

and

\[
\xi = (l_1)^0_1 : 1^1 \otimes 1^1 \xrightarrow{\sim} 1^0
\]

Let \( X_i, i \in I \) be a set of representatives of isomorphism classes\(^1\) of simple objects in a superfusion category \( \mathcal{C} \). Define

\[
J = \{(i,a) \in I \times \mathbb{Z}/2\mathbb{Z} \text{ such that } a = 0 \text{ if } X_i \text{ is Majorana}\}
\]

We denote the element \((i,a) \in J\) by \( i^a \). The isomorphism classes of simple objects in \( \mathcal{C}^+_\pi \) are labelled by \( J \). Indeed, suppose \( X_i \) is Bosonic, then we have a pair of non-isomorphic simple objects \( X^0_i \) and \( X^1_i \) in \( \mathcal{C}^+_\pi \) corresponding to the labels \( i^0 \) and \( i^1 \) respectively. If \( X_i \) is Majorana, then \( X^0_i \) and \( X^1_i \) are isomorphic in \( \mathcal{C}^+_\pi \), so we choose \( X^0_i \) as our representative simple object, and label it by \( i^0 \).

Remark 5.2. If \( \mathcal{C} \) is a Bosonic superfusion category, then the underlying fusion category \( \mathcal{C}^+_\pi \) has twice as many simple objects (up to isomorphism) as \( \mathcal{C} \), labelled by \( J = I \times \mathbb{Z}/2\mathbb{Z} \).

Example 5.3. Let \( \mathcal{C} \) be a Bosonic pointed superfusion category, as in Example 3.10. The underlying fusion category \( \mathcal{C}^+_\pi \) is pointed, so let \( G_\omega \) denote the (finite) group of isomorphism classes of simple objects in \( \mathcal{C}^+_\pi \). As a set, we have \( G_\omega = \)

\(^1\)We say that two objects in a superfusion category lie in the same isomorphism class if there is a (not necessarily even) isomorphism between them.
\( \mathbb{Z}/2\mathbb{Z} \times G \), though we would like to describe the group structure on \( G_\omega \). The isomorphisms \( e(g, h) : X_g \otimes X_h \xrightarrow{\sim} X_{gh} \) in \( C \) induce isomorphisms in \( C^+ \):

\[
e(g^a, h^b) = (e(g, h))^{a+b+\omega(g, h)} : X_g^a \otimes X_h^b \xrightarrow{\sim} X_{gh}^{a+b+\omega(g, h)}
\]

for all \( g^a, h^b \in G_\omega \), and so the group structure on \( G_\omega \) is given by

\[
g^a : h^b := (gh)^{a+b+\omega(g, h)}
\]

and so \( G_\omega \) is the central extension of \( G \) by \( \mathbb{Z}/2\mathbb{Z} \) determined by the 2-cocycle \( \omega \).

5.1. **6j symbols in** \( C^+_\mathbb{Z} \). Let \( C \) be a superfusion category, and let \( J \) label the simple objects in \( C^+_\mathbb{Z} \), as described in (8). Let \( i^a, j^b, m^c, \in J \), and suppose that \( (i, j, m, \alpha) \) is an admissable quadruple in \( C \). If \( \zeta = a + b + s^{i\alpha}(\alpha) \) then \( e^{ij}_m : X_i \otimes X_j \rightarrow X_m \) induces a morphism

\[
X_i^a \otimes X_j^b \rightarrow X_m^c
\]

in \( C^+_\mathbb{Z} \), in which case \( (i^a, j^b, m^c, \alpha) \) is an admissable quadruple in \( C^+_\mathbb{Z} \). This implies that every admissable quadruple in \( C^+_\mathbb{Z} \) can be written unambiguously in the form

\[
(i^a, j^b, m^c, \alpha)
\]

where \( i^a, j^b, m^c + b + s^{i\alpha}(\alpha) \in J \) and \( (i, j, m, \alpha) \) is an admissable quadruple in \( C \). In the same way, every admissable decuple in \( C^+_\mathbb{Z} \) can be written unambiguously as

\[
(i^a, j^b, m, k^c, n^d, t, \alpha, \beta, \eta, \varphi)
\]

where \( i^a, j^b, m^c + b + s^{i\alpha}(\alpha), t^d + c + s^{i\beta}(\beta), n^e + d + s^{i\eta}(\eta) + s^{i\varphi}(\varphi) \in J \), and \( (i, j, m, k, n, t, \alpha, \beta, \eta, \varphi) \) is a parity admissable decuple in \( C \).

**Definition 5.4.** Let \( C \) be a superfusion category, and \( C^+_\mathbb{Z} \) its underlying fusion category. If \( (i^a, j^b, m^c, n^d, t, \alpha, \beta, \eta, \varphi) \) is an admissable decuple in \( C^+_\mathbb{Z} \), let

\[
F_{k^m, n^d, \eta, \varphi}^{i^a,j^b,m^c,\alpha,\beta} := (-1)^{s^{i\alpha}(\alpha)} F_{k^m, n^d, \eta, \varphi}^{i^a,j^b,m^c,\alpha,\beta}
\]

If \( (i^a, j^b, m^c, n^d, t, \alpha, \beta, \eta, \varphi) \) is not admissable, then let \( F_{k^m, n^d, \eta, \varphi}^{i^a,j^b,m^c,\alpha,\beta} = 0 \).

We claim that the symbols defined above are in fact the \( 6j \)-symbols of \( C^+_\mathbb{Z} \). Indeed, they satisfy the following version of the pentagon equation.

**Theorem 5.5 (Pentagon equation).** Let \( C \) be a superfusion category with simple objects indexed by a set \( I \), and \( C^+_\mathbb{Z} \) the underlying fusion category. Then

\[
\sum_{k=1}^{N^{t_k}} \sum_{\eta=1}^{N^{t_\eta}} \sum_{\varphi=1}^{N^{t_\varphi}} F^{i^a,j^b,m^c,\alpha,\beta}_{k^m, n^d, \eta, \varphi} F^{i^a,j^b,m^c,\alpha,\beta}_{k^m, n^d, \eta, \varphi} F^{i^a,j^b,m^c,\alpha,\beta}_{k^m, n^d, \eta, \varphi} = \sum_{\epsilon=1}^{N^{t_\epsilon}} F^{i^a,j^b,m^c,\alpha,\beta}_{k^m, n^d, \eta, \varphi} F^{i^a,j^b,m^c,\alpha,\beta}_{k^m, n^d, \eta, \varphi}
\]
for all \(i, j, k, l, m, n, t, p, q, s \in I\), \(a, b, c \in \mathbb{Z}/2\mathbb{Z}\), and \(\alpha, \beta, \eta, \chi, \delta, \phi \in \mathbb{Z}_{\geq 0}\).

**Proof.** By combining our definition (5.4) with the super pentagon equation (5), we have the equality

\[
\sum_{\ell \in I} \sum_{\eta=1}^{N_\ell^{it}} \sum_{\kappa=1}^{N_\kappa^{it}} (-1)^{s_{\ell}^{ij}(\alpha) + d_{\eta}^{kl}(\phi) + d_{\kappa}^{ij}(\eta)} f^{ijklm} \alpha \beta f^{itn} \phi \chi f^{jklmq} k n t, \eta \phi \eta \tau_{ps}, \kappa \gamma f^{ps} \delta \phi
\]

and thus it suffices to show that

\[
c_{s_{\ell}^{ij}(\alpha)} + d_{\eta}^{kl}(\phi) + d_{\kappa}^{ij}(\eta) = s_{\eta}^{ij}(\alpha) s_{\kappa}^{kl}(\delta) + d_{\eta}^{mk}(\beta) + (c + d + s_{\kappa}^{kl}(\delta)) s_{\eta}^{ij}(\alpha)
\]

for all admissible decuples \((i, j, k, l, m, n, t, a, b, c)\) in \(C^+_\pi\). This immediately reduces to showing that

\[
d_{\eta}^{kl}(\phi) + d_{\kappa}^{ij}(\eta) = d_{\eta}^{mk}(\beta) + d_{\kappa}^{ij}(\alpha)
\]

which holds by the parity compatibility condition (4). \(\square\)

**Remark 5.6.** Our definition of the 6\(j\)-symbols in \(C^+_\pi\) can be recovered directly from the construction of \(C^+_\pi\), in which case Theorem 5.5 can be viewed as a corollary of the pentagon axiom in \(C^+_\pi\). Indeed, for each admissible quadruple \((i^2, j^2, m, a)\) in \(C^+_\pi\), let

\[(10)\]

\[
e_{m}^{ij} (\alpha) := (e_{m}^{ij} (\alpha))^{a+b+s_{m}^{ij} (\alpha)} : X^{a}_{\gamma} \otimes X^{b}_{\delta} \rightarrow X^{a+b+s_{m}^{ij} (\alpha)}_{n}
\]

For ease of notation, set \(d = a + b + s_{m}^{ij} (\alpha)\) and \(c = a + b + s_{m}^{ij} (\alpha) + s_{n}^{mk} (\beta)\), then (11) is given by

\[(11)\]

\[
(X^{a}_{\gamma} \otimes X^{b}_{\delta}) \otimes X^{c}_{k} \xrightarrow{e_{m}^{ij} (\alpha) \otimes \text{id}_{X^{c}_{k}}} X^{a}_{m} \otimes X^{b}_{k} \xrightarrow{e_{n}^{mk} (\beta) \otimes \text{id}_{X^{c}_{k}}} X^{c}_{n}
\]

where we have

\[(12)\]

\[
e_{m}^{ij} (\alpha) \otimes \text{id}_{X^{c}_{k}} = (-1)^{s_{m}^{ij} (\alpha)} (e_{m}^{ij} (\alpha) \otimes \text{id}_{X^{c}_{k}})^{c+d+e}_{a+b+c}
\]

by definition of the tensor product on \(C^+_\pi\). Next, fix an admissible quadruple \((j^k, k^t, t, \eta)\). The composition (2) is given by

\[(13)\]

\[
(X^{a}_{\gamma} \otimes X^{b}_{\delta} \otimes X^{c}_{k}) \xrightarrow{c(X^{a}_{\gamma}, X^{b}_{\delta}, X^{c}_{k})} X^{a}_{\gamma} \otimes (X^{b}_{\delta} \otimes X^{c}_{k}) \xrightarrow{\text{id}_{X^{a}_{\gamma}} \otimes e_{t}^{ijkl}(\eta)} X^{a}_{\gamma} \otimes X^{b}_{t} \xrightarrow{e_{t}^{ijkl}(\eta)} X^{c}_{n}
\]

where \(f = b + c + s_{t}^{ik}(\eta)\). We compute

\[(14)\]

\[
\text{id}_{X^{a}_{\gamma}} \otimes e_{t}^{ijkl}(\eta) = (\text{id}_{X^{a}_{\gamma}} \otimes e_{t}^{ijkl}(\eta))^{a+f}_{a+b+c}
\]
and so the compositions \([11]\) and \([13]\) in \(C_\pi^+\) are induced by the corresponding compositions \([1]\) and \([2]\) in \(C\) up to a factor of \((-1)^{c_{ij}^k}\), as expected.

**Example 5.7.** Let \(C\) be a Bosonic pointed superfusion category, as in Examples 3.10 and 5.3. For all \(g^a, h^b, k^c \in G\) we can unambiguously write \(F(g^a, h^b, k^c) \in k^x\) for the corresponding 6\(j\)-symbol in \(C_\pi^+\). With this notation Theorem 5.4 implies

\[
F(g^a, h^b, k^c) = (-1)^{c_{ij}^k} \tilde{F}(g, h, k)
\]

for all \(g^a, h^b, k^c \in G\). The pentagon equation \([9]\) implies that \(F\) is a 3-cocycle on \(G\) with values in \(k^x\).

Viewing \(G\) as the subset of \(G\) consisting of elements of the form \(g^0\), we have the following corollary.

**Corollary 5.8.** Let \(\tilde{F} : G^3 \to k^x\) be a 3-supercocycle on \(G\) with 2-cocycle \(\omega\). Then there exists a 3-cocycle \(F : G^3_\omega \to k^x\) on \(G\) such that

\[
F|_{G^3} = \tilde{F}
\]

In other words, every 3-supercocycle on \(G\) arises as the restriction of a 3-cocycle on a central extension of \(G\) by \(\mathbb{Z}/2\mathbb{Z}\).

### 6. Applications

In this section, we describe some applications of the theory of fusion categories to that of superfusion categories. In particular, we define the \(\pi\)-Grothendieck ring of a superfusion category, and prove a version of Ocneanu rigidity for superfusion categories.

**6.1. Superforms.** Let \(D\) be a \(\Pi\)-complete superfusion category. A *superform* of \(D\) is a superfusion category \(C\) such that \(C \simeq D\) are equivalent (but not necessarily superequivalent) superfusion categories. Our goal is to prove the following.

**Proposition 6.1.** A \(\Pi\)-complete superfusion category \(D\) has only finitely many superforms, up to superequivalence of superfusion categories.

To show this, the following notion will be useful.

**Definition 6.2.** Let \(C\) and \(D\) be superfusion categories, and \(F : C \to D\) a tensor superfunctor. Its *even essential image* \(F(C)\) is the full subcategory of \(D\) consisting of objects evenly isomorphic to \(F(X)\) for some \(X \in C\).

Recall that a tensor superfunctor \(F : C \to D\) is a superfunctor such that \(F(1_C)\) is evenly isomorphic to \(1_D\), together with an even natural isomorphism \(c_{X,Y} : F(X) \otimes F(Y) \xrightarrow{\sim} F(X \otimes Y)\) satisfying the usual diagram (see \([EGNO15\), §2.4]). Observe that \(F(C)\) is a full tensor subcategory of \(D\). Indeed given \(Y, Y' \in F(C)\), there exists \(X, X' \in C\) such that \(F(X) \sim Y\) and \(F(X') \sim Y'\) are evenly
isomorphic. Then $F(X \otimes X') \xrightarrow{\sim} F(X) \otimes F(X') \xrightarrow{\sim} Y \otimes Y'$ is an even isomorphism, whence $Y \otimes Y' \in F(C)$.

**Lemma 6.3.** If $F : \mathcal{C} \to \mathcal{D}$ is an equivalence of superfusion categories, then $\mathcal{C}$ is determined (up to superequivalence) by $F(\mathcal{C})$. More precisely, if $G : \mathcal{A} \to \mathcal{D}$ is an equivalence of superfusion categories with $G(\mathcal{A}) = F(\mathcal{C})$, then $\mathcal{A}$ and $\mathcal{C}$ are superequivalent superfusion categories.

**Proof.** If $X \in \mathcal{A}$, then $G(X) \in G(\mathcal{A}) = F(\mathcal{C})$, so there exists $X_\mathcal{C} \in \mathcal{C}$ such that $F(X_\mathcal{C}) \xrightarrow{\sim} G(X)$ are evenly isomorphic. For each $X \in \mathcal{A}$, we pick such a $X_\mathcal{C} \in \mathcal{C}$ together with an even isomorphism $q_X : F(X_\mathcal{C}) \xrightarrow{\sim} G(X)$. We define a superfunctor $K : \mathcal{A} \to \mathcal{C}$ as follows. On objects, let $K(X) = X_{\mathcal{C}}$. On morphisms, if $f \in \text{Hom}_\mathcal{A}(X, Y)$ then let $K(f) = F^{-1}(q_Y^{-1} \circ G(f) \circ q_X)$, i.e. $K(f)$ is the image of $f$ under the even isomorphism $\text{Hom}_\mathcal{A}(X, Y) \xrightarrow{G} \text{Hom}_\mathcal{D}(G(X), G(Y)) \xrightarrow{(q_Y^{-1}) \circ (q_X)^*} \text{Hom}_\mathcal{C}(F(X_\mathcal{C}), F(Y_\mathcal{C})) \xrightarrow{F^{-1}} \text{Hom}_\mathcal{C}(X_\mathcal{C}, Y_\mathcal{C})$

It is immediate from $K$ is fully faithful, and functorality of $F$ and $G$ implies $K$ is a superfunctor. To show that $K$ is a superequivalence, we must show that $K(\mathcal{A}) = \mathcal{C}$. Let $Y \in \mathcal{C}$, then $F(Y) \in F(\mathcal{C}) = G(\mathcal{A})$ so there exists $X \in \mathcal{A}$ together with an even isomorphism $G(X) \xrightarrow{\sim} F(Y)$, so $F(X_\mathcal{C}) \xrightarrow{\sim} F(Y)$ are evenly isomorphic. This implies that $K(X) = X_{\mathcal{C}} \xrightarrow{\sim} Y$ are evenly isomorphic, i.e. $Y \in K(\mathcal{A})$. Thus $K$ is a superequivalence.

It remains to endow $K$ with the structure of a monoidal superfunctor. To do this, we must define even coherence maps $J_{X,Y} : K(X) \otimes K(Y) \to K(X \otimes Y)$ satisfying the usual axioms. Let $c$ and $d$ denote the coherence maps for $F$ and $G$ respectively. Let $\varphi_{X,Y} : F(X_\mathcal{C} \otimes Y_\mathcal{C}) \xrightarrow{\sim} F((X \otimes Y)_\mathcal{C})$ be the composition

$$F(X_\mathcal{C} \otimes Y_\mathcal{C}) \xrightarrow{c_{X_\mathcal{C},Y_\mathcal{C}}} F(X_\mathcal{C}) \otimes F(Y_\mathcal{C}) \xrightarrow{q_X \otimes q_Y} G(X) \otimes G(Y) \xrightarrow{d_{X,Y}} G(X \otimes Y) \xrightarrow{q_{X \otimes Y}} F((X \otimes Y)_\mathcal{C})$$

With this notation, let $J_{X,Y} := F^{-1}(\varphi_{X,Y})$. It is straightforward to check that $(K, J)$ satisfies the axioms for a monoidal superfunctor, and so $K$ is a superequivalence of superfusion categories. \qed

We are now ready to prove the above proposition.

**Proof of Proposition 6.1.** Let $F : \mathcal{C} \to \mathcal{D}$ be an equivalence of superfusion categories, where $\mathcal{D}$ is $\Pi$-complete. Let $Y_i$, $i \in I$ be a set of representatives of simple objects of $\mathcal{D}$. Since $F$ is an equivalence, there exists $X_i$, $i \in I$ such that $F(X_i) \xrightarrow{\sim} Y_i$. Since $\mathcal{D}$ is $\Pi$-complete, for each $i \in I$ there exists $Y'_i \in \mathcal{D}$ such that $Y_i \xrightarrow{\sim} Y'_i$ are oddly isomorphic. Fix $i \in I$. If $Y_i$ is Majorana, then $\text{Hom}_\mathcal{D}(F(X_i), Y_i) \simeq \mathbf{k}^{[1]}$, so $Y_i \in F(\mathcal{C})$ and $Y'_i \in F(\mathcal{C})$. If $Y_i$ is Bosonic, then the space $\text{Hom}_\mathcal{D}(F(X_i), Y_i)$ is one-dimensional, either even or odd. So $Y_i \in F(\mathcal{C})$ or $Y'_i \in F(\mathcal{C})$ (or possibly both). Since the subcategory $F(\mathcal{D})$ is determined by the choice of $Y_i$ or $Y'_i$ (or both) for all $i \in I$ such that $Y_i$ is Bosonic, and there
are finitely many such choices, there are finitely many possibilities for $F(C)$. By Lemma 6.3 we are done.

Corollary 6.4. The number of superfusion categories (up to superequivalence) is countable.

Proof. Ocneanu rigidity [ENO02, Theorem 2.28, Theorem 2.31] implies there are countably many fusion categories over $s\text{Vect}$. Since every $\Pi$-complete superfusion category is the associated superfusion category of a fusion category over $s\text{Vect}$, there are countably many $\Pi$-complete superfusion categories. Every superfusion category is equivalent to a $\Pi$-complete superfusion category, so Proposition 6.1 implies the result. □

6.2. $\pi$-Grothendieck ring. Let $\mathbb{Z}^\pi = \mathbb{Z}[\pi]/(\pi^2 - 1)$ and $\mathbb{Z}_+^\pi = \{a + b\pi : a, b \in \mathbb{Z}_{\geq 0}\} \subset \mathbb{Z}^\pi$.

Definition 6.5. The $\pi$-Grothendieck group of a supercategory $C$ is the $\mathbb{Z}^\pi$-module $s\text{Gr}(C)$ generated by isomorphism classes of objects $[X]$ in $C$ subject to the relation that if $0 \to X \xrightarrow{f} Y \xrightarrow{g} Z \to 0$ is a short exact sequence with $f$ and $g$ homogeneous morphisms, then $[Y] = [X]\pi^{|f|} + [Z]\pi^{|g|}$.

If $C$ is a rigid monoidal supercategory, then the tensor product on $C$ induces an associative multiplication on $s\text{Gr}(C)$, given by $[X] \cdot [Y] := [X \otimes Y]$, making $s\text{Gr}(C)$ into a $\mathbb{Z}^\pi$-algebra.

Definition 6.6. We call $s\text{Gr}(C)$ the $\pi$-Grothendieck ring of $C$.

Example 6.7. Let $s\text{Vect}_{\text{fin}}$ denote the monoidal supercategory of finite dimensional superspaces together with all linear maps between them, and let $k^{p|q} = k^p \oplus k^q$ denote the superspace with $(k^{p|q})^0 = k^p$ and $(k^{p|q})^1 = k^q$, then $[k^{p|q}] = p[k^{1|0}] + q[k^{0|1}] = (p + q\pi)[k^{1|0}]$ in $s\text{Gr}(s\text{Vect}_{\text{fin}})$, where we used that $[k^{0|1}] = \pi[k^{0|1}]$. Since every object in $s\text{Vect}_{\text{fin}}$ is evenly isomorphic to $k^{p|q}$ for some $p$ and $q$, this implies that $s\text{Gr}(s\text{Vect}_{\text{fin}})$ is a free $\mathbb{Z}^\pi$-module, generated by $[k^{1|0}]$. Moreover, the tensor product on $s\text{Vect}_{\text{fin}}$ gives $[k^{p|q}][k^{p'|q'}] = [k^{pq' + qp' + pq'}]$ and so $s\text{Gr}(s\text{Vect}_{\text{fin}})$ is free as a $\mathbb{Z}^\pi$-algebra.

Let $C$ be a superfusion category, and $X_i$, $i \in I$ representatives of the isomorphism classes of simple objects in $C$. To each $X$ in $C$ we can canonically associate the class $[X] \in s\text{Gr}(C)$ given by the formula

\[(15) \quad [X] = \sum_i [X : X_i][X_i]\]

where

\[(16) \quad [X : X_i] = \dim \text{Hom}_C(X_i, X)_0 + \pi \dim \text{Hom}_C(X_i, X)_1 \in \mathbb{Z}^\pi\]
is the multiplicity of $X_i$ in $X$. The multiplication on $\text{sGr}(C)$ is defined by

$$[X_i] \cdot [X_j] = \sum_k [X_i \otimes X_j : X_k][X_k]$$

**Example 6.8.** Let $\mathcal{I}$ be an Ising braided category, i.e. a braided fusion category with $\text{FPdim}(\mathcal{I}) = 4$ that is not pointed, see [DGNO10, Appendix B]. Such a category contains precisely 3 isomorphism classes of simple objects: the unit object $1$, an invertible object $\pi$ and a non-invertible object $X$ satisfying the fusion rules:

$$\pi \otimes \pi \simeq 1, \quad \pi \otimes X \simeq X \otimes \pi, \quad X \otimes X \simeq 1 \oplus \pi$$

The fusion subcategory $\mathcal{I}_{ad} \subset \mathcal{I}$ generated by $1$ and $\pi$ is braided equivalent to $\text{sVect}$ [DGNO10, Lemma B.11], and thus $\mathcal{I}$ is a fusion category over $\text{sVect}$. Let us consider the associated superfusion category $\hat{\mathcal{I}}$.

The isomorphism $\pi \otimes \pi \simeq 1$ in $\mathcal{I}$ induces an odd isomorphism $\pi \sim \rightarrow 1$ in $\hat{\mathcal{I}}$. Similarly, the isomorphism $\pi \otimes X \simeq X$ in $\mathcal{I}$ induces an odd isomorphism $X \sim \rightarrow X$ in $\hat{\mathcal{I}}$. Thus $\hat{\mathcal{I}}$ has a Bosonic simple object $1 \sim \rightarrow \pi$, and a Majorana simple object $X$. From the fusion rules, we get the relations

$$[X] = \pi[X], \quad [X]^2 = (1 + \pi)[1]$$

in $\text{sGr}(\hat{\mathcal{I}})$.

**Example 6.9** (see [EGNO15, §8.18.2]). Generalising the previous example, take $k \equiv 2 \mod 4$, and let $C_k(q)$ denote the braided fusion category of integrable $\widehat{\text{sl}}_2$ modules at level $k$. This category has simple objects $V_i, i = 0, \ldots, k$ with unit object $V_0 = 1$ and fusion rule given by the truncated Clebsch-Gordan rule:

$$V_i \otimes V_j \simeq \bigoplus_{l=\max(i+j-k,0)}^{\min(i,j)} V_{i+j-2l}$$

(17)

The fusion subcategory $D_k(q) \subset C_k(q)$ generated by $1$ and $\pi := V_k$ is braided equivalent to $\text{sVect}$, and so $C_k(q)$ is a fusion category over $\text{sVect}$. Let $\hat{C}_k := \widehat{C_k(q)}$ denote the associated superfusion category.

Since $\pi \otimes V_i \simeq V_{k-i}$ in $C_k(q)$ for all $i = 0, \ldots, k$, we have $V_i \sim \rightarrow V_{k-i}$ in $\hat{C}_k$. Thus $C_k(q)$ has $k/2$ Bosonic simple objects $V_0, V_1, \ldots, V_{k/2-1}$, and a single Majorana simple object $V_{k/2}$.

Finally, we arrive at the following version of Ocneanu rigidity for superfusion categories.

**Corollary 6.10.** The number of superfusion categories (up to superequivalence) with a given $\pi$-Grothendieck ring is finite.

**Proof.** Fix a superfusion category $\mathcal{C}$, and suppose that $\mathcal{D}$ is a superfusion category with $\text{sGr}(\mathcal{C}) \simeq \text{sGr}(\mathcal{D})$. We will show that there are finitely many possibilities for $\mathcal{D}$, up to superequivalence. Since $\text{sGr}(\mathcal{C}) \simeq \text{sGr}(\mathcal{D})$, the underlying fusion
categories $\mathcal{C}_+^+$ and $\mathcal{D}_+^+$ have isomorphic Grothendieck rings. By Ocneanu rigidity [ENO02, Theorem 2.28], there are finitely many fusion categories with a given Grothendieck ring, and moreover each of these fusion categories $\mathcal{A}$ admits only finitely many tensor functors $sVect \to \mathcal{Z}(\mathcal{A})$ [ENO02, Theorem 2.31], hence there are finitely many fusion categories over $sVect$ with Grothendieck ring isomorphic to $\text{Gr}(\mathcal{C}_+^+)$. Lemma 4.10 then implies that there are finitely many possibilities for $\mathcal{D}_+^+$ up to superequivalence, so by Proposition 6.1 there are finitely many possibilities for $\mathcal{D}$ up to superequivalence. □
