E-mail: *qiying.wang@sydney.edu.au; **chanhiungai@gmail.com

For a class of martingales, this paper provides a framework on the uniform consistency with broad applicability. The main condition imposed is only related to the conditional variance of the martingale, which holds true for stationary mixing time series, stationary iterated random function, Harris recurrent Markov chains and \( f(1) \) processes with innovations being a linear process. Using the established results, this paper investigates the uniform convergence of the Nadaraya–Watson estimator in a non-linear cointegrating regression model. Our results not only provide sharp convergence rate, but also the optimal range for the uniform convergence to be held. This paper also considers the uniform upper and lower bound estimates for a functional of Harris recurrent Markov chain, which are of independent interests.

Keywords: Harris recurrent Markov chain; martingale; non-linearity; non-parametric regression; non-stationarity; uniform convergence

1. Introduction

Let \((u_k, x_k)\) with \(x_k = (x_{k1}, \ldots, x_{kd}), d \geq 1\), be a sequence of random vectors. A common functional of interests \(S_n(x)\) of \((u_k, x_k)\) is defined by

\[
S_n(x) = \sum_{k=1}^{n} u_k f\left(\frac{x_k + x}{h}\right), \quad x \in \mathbb{R}^d,
\]

(1.1)

where \(h = h_n \to 0\) is a certain sequence of positive constants and \(f(x)\) is a real function on \(\mathbb{R}^d\). Such functionals arise in non-parametric estimation problems, where \(f\) may be a kernel function \(K\) or a squared kernel function \(K^2\) and the sequence \(h\) is the bandwidth used in the non-parametric regression.

The uniform convergence of \(S_n(x)\) in the situation that the \((u_k, x_k)\) satisfy certain stationary conditions was studied in many articles. Liero [17], Peligrad [24] and Nze...
and Doukhan [21] considered the uniform convergence over a fixed compact set, while Masry [19], Bosq [2] and Fan and Yao [8] gave uniform results over an unbounded set. These work mainly focus on random sequence $x_t$ which satisfies different types of mixing conditions. Investigating a more general framework, Andrews [1] gave result on kernel estimate when the data sequence is near-epoch dependent on another underlying mixing sequence. More recently, Hansen [12] provided a set of general uniform consistency results, allowing for stationary strong mixing multivariate data with infinite support, kernels with unbounded support and general bandwidth sequences. Kristensen [16] further extended Hansen’s results to the heterogenous dependent case under $\alpha$-mixing condition. Also see Wu, Huang and Huang [32] for kernel estimation in general time series settings.

In comparison to the extensive results where the $x_k$ comes from a stationary time series data, there is little investigation on the the uniform convergence of $S_n(x)$ for the $x_k$ being a non-stationary time series. In this regard, Gao, Li and Tjøstheim [11] derived strong and weak consistency results for the case where the $x_k$ is a null-recurrent Markov chain. Wang and Wang [31] worked with partial sum processes of the type $x_k = \sum_{j=1}^k \xi_j$ where $\xi_j$ is a general linear process. While the rate of convergence in Gao, Li and Tjøstheim [11] is sharp, they impose the independence between $u_k$ and $x_k$. Using a quite different method, Wang and Wang [31] allowed for the endogeneity between $u_k$ and $x_k$, but their results hold only for the $x$ being in a fixed compact set.

The aim of this paper is to present a general uniform consistency result for $S_n(x)$ with broad applicability. As a framework, our assumption on the $x_t$ is only related to the conditional variance of the martingale, that is, $\sum_{t=1}^n f^2[(x_t + x)/\theta]$. See Assumption 2.3 in Section 2. This of course is a “high level” condition, but it in fact is quite natural which holds true for many interesting and important examples, including stationary mixing time series, stationary iterated random function and Harris recurrent Markov chain. See Sections 2.2 and 2.3 for the identification of Assumption 2.3. This condition also holds true for $I(1)$ processes with innovations being a linear process, but the identification is complicated and requires quite different techniques. We will report related work in a separate paper. By using the established result, we investigate the uniform convergence of the Nadaraya–Watson estimator in a non-linear cointegrating regression model. It confirms that the uniform asymptotics in Wang and Wang [31] can be extended to a unbounded set and the independence between the $u_t$ and $x_t$ in Gao, Li and Tjøstheim [11] can be removed. More importantly, our result not only provides sharp convergence rate, but also the optimal range for the uniform convergence to be held. It should be mentioned that our work on the uniform upper and lower bound estimation for a functional of Harris recurrent Markov chain is of independent interests.

This paper is organized as follows. Our main results are presented in next section, which includes the establishment of a framework on the uniform convergence for a class of martingale and uniform upper and lower bound estimation for a functional of Harris recurrent Markov chain. An application of the main results in non-linear cointegrating regression is given in Section 3. All proofs are postponed to Section 4. Throughout the paper, we denote constants by $C, C_1, C_2, \ldots$ which may be different at each appearance. We also use the notation $\|x\| = \max_{1 \leq i \leq d} |x_i|$.
Uniform convergence rates for a class of martingales

2. Main results

2.1. Uniform convergence for a class of martingales

We make use of the following assumptions in the development of uniform convergence for the $S_n(x)$ defined by (1.1). Recall $x_k = (x_{k1}, \ldots, x_{kd})$ where $d \geq 1$ is an integer.

**Assumption 2.1.** \{${u_t, \mathcal{F}_t} \}_{t \geq 1}$ is a martingale difference, where $\mathcal{F}_t = \sigma(x_1, \ldots, x_{t+1}, u_1, \ldots, u_t)$, satisfying $\sup_{t \geq 1} E(|u_t|^p | \mathcal{F}_{t-1}) < \infty$, a.s., for some $p \geq 1$ specified in Assumption 2.4 below.

**Assumption 2.2.** $f(x)$ is a real function on $\mathbb{R}^d$ satisfying $\sup_{x \in \mathbb{R}^d} |f(x)| < \infty$ and $|f(x) - f(y)| \leq C \|x - y\|$ for all $x, y \in \mathbb{R}^d$ and some constant $C > 0$.

**Assumption 2.3.** There exist positive constant sequences $c_n \uparrow \infty$ and $b_n$ with $b_n = O(n^k)$ for some $k > 0$ such that

$$\sup_{\|x\| \leq b_n} \sum_{t=1}^{n} f^2[(x_t + x)/h] = O_P(c_n). \quad (2.1)$$

**Assumption 2.4.** $h \to 0, nh \to \infty$ and $nc_n^{-p} \log^{p-1} n = O(1)$, where $c_n$ is defined as in Assumption 2.3 and $p$ is defined as in Assumption 2.1.

We remark that Assumption 2.1 ensures that \{${S_n(x), \mathcal{F}_n} \}_{n \geq 1}$ is a martingale for each fixed $x$ and is quite weak. Clearly, Assumption 2.1 is satisfied if $u_t$ is a sequence of i.i.d. random variables, which is independent of $x_1, \ldots, x_t$, with $E u_1 = 0$ and $E |u_1|^p < \infty$. The Lipschitz condition used in Assumption 2.2 is standard in the investigation of uniform consistency, where we do not require the $f(x)$ to have finite compact support. Assumption 2.3 is a “high level” condition for the $x_k$. We use it here to provide a framework. In Sections 2.2 and 2.3, we will show that this condition is in fact quite natural which holds true by many interesting and important examples. Assumption 2.4 provides the connections among the moment condition required in Assumption 2.1, the condition (2.1) and the bandwidth $h$. In many applications, we have $c_n = n^\alpha h^{d}l(n)$, where $0 < \alpha \leq 1$ and $l(n)$ is a slowly varying function at infinite. See Section 2.3 and Examples 1–3 in Section 2.2. In the typical situation that $c_n = n^\alpha h^{d}l(n)$, if there exists a $0 < \varepsilon_0 < \alpha$ such that $n^{\alpha-\varepsilon_0}h^{d} \to \infty$, the $p$ required in Assumption 2.1 can be specified to $p = [1/\varepsilon_0] + 1$.

We have the following main result.

**Theorem 2.1.** Under Assumptions 2.1–2.4, we have

$$\sup_{\|x\| \leq b_n} \left| \sum_{t=1}^{n} u_t f[(x_t + x)/h] \right| = O_P[(c_n \log n)^{1/2}]. \quad (2.2)$$
If (2.1) is replaced by
\[
\sup_{\|x\| \leq b_n} \sum_{t=1}^{n} f^2([x_t + x]/h) = O(c_n), \quad a.s.,
\] (2.3)
the result (2.2) can be strengthened to
\[
\sup_{\|x\| \leq b_n} \left| \sum_{t=1}^{n} u_t f([x_t + x]/h) \right| = O([c_n \log n]^{1/2}), \quad a.s.
\] (2.4)

Theorem 2.1 can be extended to uniform convergence for the \( S_n(x) = \sum_{t=1}^{n} u_t f([x_t + x]/h) \) over unrestricted space \( \mathbb{R}^d \). This requires additional condition on the \( x_k \) and the tail decay for the function \( f(x) \).

**Theorem 2.2.** In addition to Assumptions 2.1–2.4, \( n \sup_{\|x\| > b_n / 2} |f(x/h)| = O([c_n \log n]^{1/2}) \) and there exists a \( k_0 > 0 \) such that
\[
b_n^{-k_0} \sum_{t=1}^{n} E \|x_t\|^{k_0} = O([c_n \log n]^{1/2}).
\] (2.5)
Then,
\[
\sup_{x \in \mathbb{R}^d} \left| \sum_{t=1}^{n} u_t f([x_t + x]/h) \right| = O_P([c_n \log n]^{1/2}).
\] (2.6)
Similarly, if (2.1) is replaced by (2.3) and (2.5) is replaced by
\[
b_n^{-k_0} \sum_{t=1}^{n} \|x_t\|^{k_0} = O([c_n \log n]^{1/2}), \quad a.s.,
\] (2.7)
then
\[
\sup_{x \in \mathbb{R}^d} \left| \sum_{t=1}^{n} u_t f([x_t + x]/h) \right| = O([c_n \log n]^{1/2}), \quad a.s.
\] (2.8)

**Remark 2.1.** Theorems 2.1–2.2 allow for the \( x_t \) to be a stationary or non-stationary time series. See Examples 1–3 and Section 2.3 below. More examples on non-stationary time series will be reported in a separate paper. The rates of convergence in both theorems are sharp. For instance, in the well-known stationary situation such as those appeared in Examples 1–3, the \( c_n \) can be chosen as \( c_n = nh \). Hence, when there are enough moment conditions on the \( u_t \) (i.e., \( p \) is large enough), we obtain the optimal rate \( n^{2/5} \log^{3/5} n \), by taking \( h \sim (\log n/n)^{1/5} \). In non-stationary situation, the rate of convergence is different. In particular we have \( c_n = \sqrt{nh} \) for the \( x_t \) to be a random walk given in Corollary 2.1. The reason behind this fact is that the amount of time spent by the random walk around
any particular point is of order \(\sqrt{n}\) rather than \(n\) for a stationary time series. For more explanation in this regard, we refer to Wang and Phillips [27, 28].

2.2. Identifications of Assumption 2.3

This section provides several stationary time series examples which satisfy Assumption 2.3. Examples 1 and 2 come from Wu, Huang and Huang [32], where more general settings on the \(x_t\) are established. Example 3 discusses a strongly mixing time series. This example comes from Hansen [12]. By making use of other related works such as Peligrad [24], Nze and Doukhan [21], Masry [19], Bosq [2] and Andrews [1], similar results can be established for other mixing time series like \(\rho\)-mixing and near-epoch-dependent time series. In these examples, we only consider the situation that \(d = 1\). The extension to \(d > 1\) is straightforward and hence the details are omitted. Throughout Examples 1–3, we use the notation \(f^2_h(x) = h^{-1} f^2(x/h)\).

Example on the Harris recurrent Markov chains, which allows for stationary (positive recurrent) or non-stationary (null recurrent) series, is given in Section 2.3. In the section, we also consider the uniform lower bound, which is of independent interests. More examples on \(I(1)\) processes with innovations being linear processes will be reported in a separate paper.

**Example 1.** Let \(\{x_t\}_{t \geq 0}\) be a linear process defined by

\[
x_t = \sum_{k=0}^{\infty} \phi_k \varepsilon_{t-k},
\]

where \(\{\varepsilon_j\}_{j \in \mathbb{Z}}\) is a sequence of i.i.d. random variables with \(E \varepsilon_1^2 < \infty\) and a density \(p_\varepsilon\) satisfying \(\sup_{x \in \mathbb{R}} |p_\varepsilon^{(r)}(x)| < \infty\) and

\[
\int_{\mathbb{R}} |p_\varepsilon^{(r)}(x)|^2 \, dx < \infty, \quad r = 0, 1, 2,
\]

where \(p_\varepsilon^{(r)}(x)\) denotes the \(r\)-order derivative of \(p_\varepsilon(x)\). Suppose that \(\sum_{k=0}^{\infty} |\phi_k| < \infty\) and \(\phi = \sum_{k=0}^{\infty} \phi_k \neq 0\), and in addition Assumption 2.2, \(f(x)\) has a compact support. It follows from Section 4.1 of Wu, Huang and Huang [32] that, for any \(h \rightarrow 0\) and \(nh \log^{-1} n \rightarrow \infty\),

\[
\sup_{x \in \mathbb{R}} \left| \frac{1}{n} \sum_{i=1}^{n} [f^2_{h}(x_t + x) - Ef^2_{h}(x_t + x)] \right| = O \left[ \sqrt{\frac{\log n}{nh}} + n^{-1/2} l(n) \right], \quad \text{a.s.,} \quad (2.9)
\]

where \(l(n)\) is a slowly varying function. Note that \(x_t\) is stationary process with a bounded density \(g(x)\) under the given conditions on \(\varepsilon_k\). Simple calculations show that

\[
\sup_{x \in \mathbb{R}} \sum_{t=1}^{n} f^2_{h}(x_t + x)/h = O_P(nh), \quad (2.10)
\]

that is, \(x_t\) satisfies Assumption 2.3.
Example 2. Consider the non-linear time series of the following form

\[ x_k = R(x_{k-1}, \varepsilon_k), \]

where \( R \) is a bivariate measurable function and \( \varepsilon_k \) are i.i.d. innovations. This is the iterated random function framework that encompasses a lot of popular non-linear time series models. For example, if \( R(x, \varepsilon) = a_1 I(x < \tau) + a_2 I(x \geq \tau) + \varepsilon \), it is the threshold autoregressive (TAR) model (see Tong [25]). If \( R(x, \varepsilon) = \varepsilon \sqrt{a_1^2 + a_2^2} x \), then it is autoregressive model with conditional heteroscedasticity (ARCH) model. Other non-linear time series models, including random coefficient model, bilinear autoregressive model and exponential autoregressive model can be fitted in this framework similarly. See Wu and Shao [33] for details.

In order to identify Assumption 2.3, we need some regularity conditions on the initial distribution of \( x_0 \) and the function \( R(x, \varepsilon) \). Define

\[ L_\varepsilon = \sup_{x \neq x'} \frac{|R(x, \varepsilon) - R(x', \varepsilon)|}{|x - x'|}. \quad (2.11) \]

Denote by \( g(x \mid x_0) \) the conditional density of \( x_1 \) at \( x \) given \( x_0 \). Further let \( g'(y \mid x) = \partial g(y \mid x)/\partial y \) and

\[ I(x) = \left[ \int_R \left| \frac{\partial}{\partial x} g(y \mid x) \right|^2 \, dy \right]^{1/2} \quad \text{and} \quad J(x) = \left[ \int_R \left| \frac{\partial}{\partial x} g'(y \mid x) \right|^2 \, dy \right]^{1/2}, \quad (2.12) \]

\( I(x) \) and \( J(x) \) can be interpreted as a prediction sensitivity measure. These quantities measure the change in 1-step predictive distribution of \( x_1 \) with respect to change in initial value \( x_0 \). Suppose that:

(i) there exist \( \alpha \) and \( z_0 \) such that

\[ E(|L_{\varepsilon_0}|^\alpha + |R(z_0, \varepsilon_0)|^\alpha) < \infty, \quad E[\log(L_{\varepsilon_0})] < 0 \quad \text{and} \quad EL_{\varepsilon_0}^2 < 1; \]

(ii) \( \sup_{x} |I(x) + J(x)| < \infty; \)

(iii) in addition to Assumption 2.2, \( f(x) \) has a compact support.

It follows from Section 4.2 of Wu, Huang and Huang [32] that, for any \( h \to 0 \) and \( nh \log^{-1} n \to \infty \)

\[ \sup_{x \in R} \left| \frac{1}{n} \sum_{t=1}^{n} [f^2_h(x_t + x) - Ef^2_h(x_t + x)] \right| = O \left[ \sqrt{\frac{\log n}{nh}} + n^{-1/2} l(n) \right], \quad \text{a.s.}, \quad (2.13) \]

where \( l(n) \) is a slowly varying function. Note that \( x_t \) has a unique and stationary distribution under the given condition (i) and (ii). See Diaconis and Freedman [7], for instance. Simple calculations show that

\[ \sup_{x \in R} \sum_{t=1}^{n} f^2((x_t + x)/h) = O_P(nh), \quad (2.14) \]

that is, \( x_t \) satisfies Assumption 2.3.
Example 3. Let \( \{x_k\}_{k \geq 0} \) be a strictly stationary time series with density \( g(x) \). Suppose that:

(i) \( x_t \) is strongly mixing with mixing coefficients \( \alpha(m) \) that satisfy \( \alpha(m) \leq Am^{-\beta} \) where \( \beta > 2 \) and \( A < \infty \);

(ii) \( \sup_x |x|^q g(x) < \infty \) for some \( q \geq 1 \) satisfying \( \beta > 2 + 1/q \) and there is some \( j^* < \infty \) such that for all \( j \geq j^* \), \( \sup_{x,y} g_j(x,y) < \infty \) where \( g_j(x,y) \) is the joint density of \( \{x_0,x_j\} \);

(iii) in addition to Assumption 2.2, \( f(x) \) has a compact support.

It follows from Theorem 4 (with \( Y_i = 1 \)) of Hansen [12] that, for any \( h \to 0 \) and \( n^\theta h \log n^{-1} \to \infty \) with \( \theta = \beta - 2 - 1/q \),

\[
\sup_{x \in \mathbb{R}} \left| \frac{1}{n} \sum_{i=1}^{n} \left[ f(x_t + x) - Ef(x_t + x) \right] \right| = O_P \left( \sqrt{\log n/nh} \right). \tag{2.15}
\]

If in addition \( E|x_0|^{2q} < \infty \), the result (2.15) can be strengthened to almost surely convergence. Simple calculations show that

\[
\sup_{x \in \mathbb{R}} \sum_{i=1}^{n} f^2 \left( \frac{x_t + x}{h} \right) = O_P(nh), \tag{2.16}
\]

that is, \( x_t \) satisfies Assumption 2.3.

2.3. Uniform bounds for functionals of Harris recurrent Markov chain

Let \( \{x_k\}_{k \geq 0} \) be a Harris recurrent Markov chain with state space \( (E,\mathcal{E}) \), transition probability \( P(x,A) \) and invariant measure \( \pi \). We denote \( P_{\mu} \) for the Markovian probability with the initial distribution \( \mu \), \( E_{\mu} \) for correspondent expectation and \( P^k(x,A) \) for the \( k \)-step transition of \( \{x_k\}_{k \geq 0} \). A subset \( D \) of \( E \) with \( 0 < \pi(D) < \infty \) is called \( D \)-set of \( \{x_k\}_{k \geq 0} \) if for any \( A \in \mathcal{E}^+ \),

\[
\sup_{x \in E} \sum_{k=1}^{\tau_A} I_D(x_k) < \infty,
\]

where \( \mathcal{E}^+ = \{ A \in \mathcal{E}: \pi(A) > 0 \} \) and \( \tau_A = \inf\{ n \geq 1: x_n \in A \} \). As is well-known, \( D \)-sets not only exist, but generate the entire sigma \( \mathcal{E} \), and for any \( D \)-sets \( C,D \) and any probability measure \( \nu, \mu \) on \( (E,\mathcal{E}) \),

\[
\lim_{n \to \infty} \sum_{k=1}^{n} \nu P^k(C)/\sum_{k=1}^{n} \mu P^k(D) = \frac{\pi(C)}{\pi(D)}. \tag{2.17}
\]

where \( \nu P^k(D) = \int_{-\infty}^{\infty} P^k(x,D) \nu(dx) \). See Nummelin [20], for instance.
Let a $D$-set $D$ and a probability measure $\nu$ on $(E, \mathcal{E})$ be fixed. Define
\[ a(t) = \pi^{-1}(D) \sum_{k=1}^{[t]} \nu P^k(D), \quad t \geq 0. \]
By recurrence, $a(t) \to \infty$. By virtue of (2.17), the asymptotic order of $a(t)$ depends only on $\{x_k\}_{k \geq 0}$. As in Chen [5], a Harris recurrent Markov chain $\{x_k\}_{k \geq 0}$ is called $\beta$-regular if
\[ \lim_{\lambda \to \infty} a(\lambda t)/a(\lambda) = t^\beta \quad \forall t > 0, \quad (2.18) \]
where $0 < \beta \leq 1$. It is interesting to notice that, under the condition (2.18), the function $a(t)$ is regularly varying at infinity, that is, there exists a slowly varying function $l(x)$ such that $a(t) \sim t^\beta l(t)$. This implies that the definition of $\beta$-regular Harris recurrent Markov chain is similar to that of $\beta$-null recurrent given in Karlsen and Tjøstheim [14] and Gao, Li and Tjøstheim [11], but it is more natural and simple.

The following theorem provides uniform upper and lower bounds for a functional of $x_t$. The upper bound implies that $x_t$ satisfies Assumption 2.3, allowing for the $x_t$ being stationary ($\beta = 1$, positive recurrent Markov chain) and non-stationary ($0 < \beta < 1$, null recurrent Markov chain). The lower bound plays a key role in the investigation of the uniform consistency for the kernel estimator in a non-linear cointegrating regression, and hence is of independent interests. See Section 3 for more details. Both upper and lower bounds are optimal, which is detailed in Remarks 2.2 and 2.3.

**Theorem 2.3.** Suppose that:

(i) $\{x_k\}_{k \geq 0}$ is a $\beta$-regular Harris recurrent Markov chain, where the invariant measure $\pi$ has a bounded density function $p(s)$ on $R$;
(ii) in addition to Assumption 2.2, $\int_{-\infty}^{\infty} |f(x)| \, dx < \infty$.

Then, for any $h > 0$ satisfying $n^{-\varepsilon_0} a(n) h \to \infty$ for some $\varepsilon_0 > 0$, we have
\[ \sup_{|x| \leq mn} \sum_{k=1}^{n} f^2[(x_k + x)/h] = O_P[a(n)h], \quad (2.19) \]
where $m$ can be any finite integer.

For a given sequence of constants $b_n > 0$, if there exists a constant $C_0 > 0$ such that, uniformly for $n$ large enough,
\[ \inf_{|x| \leq b_n + 1} \sum_{k=1}^{n} E f^2[(x_k + x)/h] \geq a(n)h/C_0, \quad (2.20) \]
then, for any $h > 0$ satisfying $n^{-\varepsilon_0} a(n) h \to \infty$ for some $\varepsilon_0 > 0$, we have
\[ \left\{ \inf_{|x| \leq b_n} \sum_{k=1}^{n} f^2[(x_k + x)/h] \right\}^{-1} = O_P\{a(n)h^{-1}\}. \quad (2.21) \]
Remark 2.2. The result (2.21) implies that, for any $0 < \eta < 1$, there exists a constant $C_\eta > 0$ such that
\[
P\left( \inf_{|x| \leq b_n} \sum_{k=1}^{n} f^2[(x_k + x)/h] \geq a(n)h/C_\eta \right) \geq 1 - \eta. \tag{2.22}
\]
This makes both bounds on (2.19) and (2.21) are optimal. On the other hand, since the result (2.22) implies that
\[
E \inf_{|x| \leq b_n} \sum_{k=1}^{n} f^2[(x_k + x)/h] \geq a(n)h(1 - \eta)/C_\eta
\]
for any $0 < \eta < 1$, the condition (2.20) is close to minimal.

Note that random walk is a $1/2$-regular Harris recurrent Markov chain. The following corollary on a random walk shows the range $|x| \leq b_n$ can be taken to be optimal as well.

Corollary 2.1. Let $\{\varepsilon_j, 1 \leq j \leq n\}$ be a sequence of i.i.d. random variables with $E\varepsilon_0 = 0$, $E\varepsilon_0^2 = 1$ and the characteristic function $\varphi(t)$ of $\varepsilon_0$ satisfying $\int_{-\infty}^{\infty} |\varphi(t)| dt < \infty$. Write $x_t = \sum_{j=1}^{t} \varepsilon_j$, $t \geq 1$. If in addition to Assumption 2.2, $\int_{-\infty}^{\infty} |f(x)| dx < \infty$, then, for $h > 0$ and $n^{1/2-\varepsilon_0} h \to \infty$ where $0 < \varepsilon_0 < 1/2$, we have
\[
\sup_{|x| \leq n^m} \sum_{k=1}^{n} f^2[(x_k + x)/h] = O_P(\sqrt{n}h) \tag{2.23}
\]
for any integer $m > 0$, and
\[
\left\{ \inf_{|x| \leq \tau_n \sqrt{n}} \sum_{k=1}^{n} f^2[(x_k + x)/h] \right\}^{-1} = O_P((\sqrt{n}h)^{-1}) \tag{2.24}
\]
for any $0 < \tau_n \to 0$.

Remark 2.3. For a random walk $x_t$ defined as in Corollary 2.1, it was shown in Wang and Phillips [27] that
\[
\frac{1}{\sqrt{n}h} \sum_{t=1}^{n} f^2[(x_t + y_n)/h] \to D \int f^2(s) ds L_W(1, y), \tag{2.25}
\]
where $L_W(1, y)$ is a local time of a Brownian motion $W_t$, and $y = 0$ if $y_n/\sqrt{n} \to 0$ and $y = y_0$ if $y_n/\sqrt{n} \to y_0$. Since $P(L_W(1, y) = 0) > 0$ for any $y \neq 0$, it follows from (2.25) that the range $\inf_{|x| \leq \tau_n \sqrt{n}}$ in (2.24) cannot be extended to $\inf_{|x| \leq d \sqrt{n}}$ for any $d > 0$.

Remark 2.4. As in Examples 1–3, we may obtain a better result if $\{x_t\}_{t \geq 0}$ is stationary (positive null recurrent) and satisfies certain other restrictive conditions. Indeed, Kristensen [16] provided such a result.
Let \( \{x_n\}_{n \geq 0} \) be a time-homogeneous, geometrically ergodic Markov chain. Denote the 1-step transition probability by \( p(y \mid x) \), such that \( P(x_{i+1} \in A \mid x_i) = \int_A p(y \mid x) \, dy \). Also denote the \( i \)-step transition probability by \( p_i(y \mid x) \), such that \( p_i(y \mid x) = \int p(y \mid z) p_{i-1}(z \mid x) \, dz \). Since \( x_t \) is geometrically ergodic, it has a density \( g(x) \). Further suppose that:

\begin{enumerate}
  \item \text{(strong Doeblin condition)} there exists \( s \geq 1 \) and \( \rho \in (0, 1) \) such that for all \( y \in \mathbb{R} \),
  \[
  p_s(y \mid x) \geq \rho g(y); \tag{2.26}
  \]
  \item \( \partial^r p(y \mid x) / \partial y^r \) exists and is uniformly continuous for all \( x \), for some \( r \geq 1 \),
  \item \( \sup_y [g(y) + |y|^q g(y)] < \infty \) for some \( q \geq 1 \),
  \item in addition to Assumption 2.2, \( f(x) \) has a compact support.
\end{enumerate}

It follows from Kristensen [16] that, for any \( h \to 0 \) and \( nh \to \infty \),
\[
\sup_{x \in \mathbb{R}} \left| \frac{1}{nh} \sum_{t=1}^{n} f^2((x_t + x)/h) - g(x) \int f^2(s) \, ds \right| = O_P \left( h^r + \sqrt{\frac{\log n}{nh}} \right), \tag{2.27}
\]
which yields (2.19) with \( a(n) = n \) and (2.21) with \( a(n) = n \) and \( b_n = C_0 \), where \( C_0 \) is a constant such that \( \inf_{|x| \leq C_0} g(x) > 0 \).

**Remark 2.5.** It is much more complicated if \( x_t \) is a null recurrent Markov chain, even in the simple situation that \( x_t \) is a random walk defined as in Corollary 2.1. In this regard, we have (2.25), but it is not clear at the moment if it is possible to establish a result like
\[
\sup_{|x| \leq b_n} \left| \frac{1}{\sqrt{nh}} \sum_{t=1}^{n} f^2((x_t + x)/h) - \int f^2(s) \, ds L_W(1, x) \right| = O_P(c_n) \tag{2.28}
\]
for some \( b_n \to \infty \) and \( c_n \to 0 \). Note that (2.28) implies that
\[
\frac{1}{\sqrt{nh}} \sum_{t=1}^{n} f^2((x_t + y)/h) \to P \left( \int f^2(s) \, ds L_W(1, 0) \right) \tag{2.29}
\]
for any fixed \( y \). This is a stronger convergence than that given in (2.25). Our experiences show that it might not be possible to prove (2.28) without enlarging the probability space in which the \( x_t \) hosts.

### 3. Applications in non-linear cointegrating regression

Consider a non-linear cointegrating regression model:
\[
y_t = m(x_t) + u_t, \quad t = 1, 2, \ldots, n, \tag{3.1}
\]
where \( u_t \) is a stationary error process and \( x_t \) is a non-stationary regressor. Let \( K(x) \) be a non-negative real function and set \( K_h(s) = h^{-1} K(s/h) \) where \( h \equiv h_n \to 0 \). The
conventional kernel estimate of \( \hat{m}(x) \) in model (3.1) is given by
\[
\hat{m}(x) = \frac{\sum_{i=1}^{n} y_i K_h(x - x_i)}{\sum_{i=1}^{n} K_h(x - x_i)}.
\]

The point-wise limit behavior of \( \hat{m}(x) \) has currently been investigated by many authors. Among them, Karlsen, Myklebust and Tjøstheim [13] discussed the situation where \( x_t \) is a recurrent Markov chain. Wang and Phillips [28, 29] and Cai, Li and Park [3] considered an alternative treatment by making use of local time limit theory and, instead of recurrent Markov chains, worked with partial sum representations of the type \( x_t = \sum_{j=1}^{\infty} \xi_j \) where \( \xi_j \) is a general linear process. In another paper, Wang and Phillips [28] considered the errors \( u_t \) to be serially dependent and cross correlated with the regressor \( x_t \) for small lags. For other related works, we refer to Kasparis and Phillips [15], Park and Phillips [22, 23], Gao et al. [9, 10], Marmer [18], Chen, Li and Zhang [4], Wang and Phillips [30] and Wang [26].

This section provides a uniform convergence for the \( \hat{m}(x) \) by making direct use of Theorems 2.1 and 2.3 in developing the asymptotics. For reading convenience, we list the assumptions as follows.

**Assumption 3.1.**
(i) \( \{x_k\}_{k \geq 0} \) is a \( \beta \)-regular Harris recurrent Markov chain defined as in Section 3, where the invariant measure \( \pi \) has a bounded density function \( p(s) \) on \( R \); (ii) \( \{u_t, \mathcal{F}_t\}_{t \geq 1} \) is a martingale difference, where \( \mathcal{F}_t = \sigma(x_1, \ldots, x_{t+1}, u_1, \ldots, u_t) \), satisfying \( \sup_{t \geq 1} E(|u_t|^{2p} | \mathcal{F}_{t-1}) < \infty \), where \( p \geq 1 + 1/\varepsilon_0 \) for some \( 0 < \varepsilon_0 < \beta \).

**Assumption 3.2.** The kernel \( K \) satisfies that \( \int_{-\infty}^{\infty} K(s) \, ds < \infty \), \( \sup_x K(x) < \infty \) and for any \( x, y \in R \),
\[
|K(x) - K(y)| \leq C|x - y|.
\]

**Assumption 3.3.** There exists a real positive function \( g(x) \) such that
\[
|m(y) - m(x)| \leq C|y - x|^\alpha g(x),
\]
uniformly for some \( 0 < \alpha \leq 1 \) and any \( (x, y) \in \Omega_\varepsilon \), where \( \varepsilon \) can be chosen sufficiently small and \( \Omega_\varepsilon = \{(x, y) : |y - x| \leq \varepsilon, x \in R\} \).

Assumption 3.1 is similar to, but weaker than those appeared in Karlsen, Myklebust and Tjøstheim [13], where the authors considered the point-wise convergence in distribution.

Assumption 3.2 is a standard condition on \( K(x) \) as in the stationary situation. The Lipschitz condition on \( K(x) \) is not necessary if we only investigate the point-wise asymptotics. See Remark 3.2 for further details.

Assumption 3.3 requires a Lipschitz-type condition in a small neighborhood of the targeted set for the functionals to be estimated. This condition is quite weak, which may host a wide set of functionals. Typical examples include that \( m(x) = \theta_1 + \theta_2 x + \cdots + \theta_k x^{k-1}; \ m(x) = \alpha + \beta x^\gamma; \ m(x) = x(1 + \theta x)^{-1} I(x \geq 0); \ m(x) = (\alpha + \beta x^\gamma)/(1 + e^x) \).
We have the following asymptotic results.

**Theorem 3.1.** Suppose Assumptions 3.1–3.3 hold, $h \to 0$ and $n^{-\varepsilon_0} a(n) h \to \infty$ where $0 < \varepsilon_0 < \beta$ is given as in Assumption 3.1. It follows that

$$
\sup_{|x| \leq b'_n} |\hat{m}(x) - m(x)| = O_P\{[a(n)h]^{-1/2} \log^{1/2} n + h^0 \delta_n\},
$$

(3.3)

where $b'_n \leq b_n$, $\delta_n = \sup_{|x| \leq b'_n} g(x)$ and $b_n$ satisfies that

$$
\inf_{|x| \leq b_n+1} \sum_{k=1}^n E K^2(x_k - x)/h \geq a(n)h/C_0
$$

for some $C_0 > 0$ and all $n$ sufficiently large. In particular, for the random walk $x_t$ defined as in Corollary 2.1, we have

$$
\sup_{|x| \leq b'_n} |\hat{m}(x) - m(x)| = O_P\{(nh^2)^{-1/4} \log^{1/2} n + h^0 \delta_n\},
$$

(3.4)

where $b'_n \leq \tau_n \sqrt{n}$ for some $0 < \tau_n \to 0$ and $\delta_n = \sup_{|x| \leq b'_n} g(x)$.

**Remark 3.1.** When a high moment exists on the error $u_t$, the $\varepsilon_0$ can be chosen sufficiently small so that there are more bandwidth choices in practice. It is understandable that the results (3.3) and (3.4) are meaningful if only $h^0 \delta_n \to 0$, which depends on the tail of the unknown regression function $m(x)$, the bandwidth $h$ and the range $|x| \leq b'_n$. When $m(x)$ has a light tail such as $m(x) = (\alpha + \beta e^x)/(1 + e^x)$, $\delta_n$ may be bounded by a constant. In this situation, the $b'_n$ in (3.4) can be chosen to be $\tau_n \sqrt{n}$ for some $0 < \tau_n \to 0$. In contrast to Theorem 2.3 and Remark 2.3, this kind of range $|x| \leq \tau_n \sqrt{n}$ might be optimal, that is, the $b'_n$ cannot be improved to $d \sqrt{n}$, for any $d > 0$, to establish the same rate of convergence as in (3.4).

**Remark 3.2.** Both results (3.3) and (3.4) are sharp. However, a better result can be obtained if we are only interested in the point-wise asymptotics for $\hat{m}(x)$. For instance, as in Wang and Phillips [27, 28] with minor modification, we may show that, for each $x$,

$$
\hat{m}(x) - m(x) = O_P\{(nh^2)^{-1/4} + h^0\},
$$

(3.5)

whenever $x_t$ is a random walk defined as in Corollary 2.1. Furthermore $\hat{m}(x)$ has an asymptotic distribution that is mixing normal, under minor additional conditions. More details are referred to Wang and Phillips [27, 28].

**Remark 3.3.** Wang and Wang [31] established a similar result to (3.4) with the $x_t$ being a partial sum of linear process, but only for the $x$ being a compact support and imposing a bounded condition on $u_t$. The setting on the $x_t$ in this paper is similar to that given in Gao, Li and Tjøstheim [11], but our result provides the optimal range for the uniform convergence holding true and removes the independence between the error $u_t$ and $x_t$ required by Gao, Li and Tjøstheim [11].
4. Proofs of main results

Proof of Theorem 2.1. We split the set \( A_n = \{ x : \| x \| \leq b_n \} \) into \( m_n \) balls of the form
\[
A_{nj} = \{ x : \| x - y_j \| \leq 1/m_n' \},
\]
where \( m_n' = [nh^{-1}/(c_n \log n)^{1/2}] \), \( m_n = (b_n m_n')^d \) and \( y_j \) are chosen so that \( A_n \subset \bigcup A_{nj} \).

It follows that
\[
\sup_{\| x \| \leq b_n} \left| \sum_{t=1}^n u_t f \left( x_t + x/h \right) \right|
\leq \max_{0 \leq j \leq m_n} \sup_{x \in A_{nj}} \sum_{t=1}^n |u_t| |f((x_t + x)/h) - f((x_t + y_j)/h)|
+ \max_{0 \leq j \leq m_n} \left| \sum_{t=1}^n u_t f((x_t + y_j)/h) \right|
:= \lambda_{1n} + \lambda_{2n}.
\]

Recalling the Assumption 2.2, it is readily seen that
\[
\lambda_{1n} \leq \sum_{t=1}^n |u_t| \max_{0 \leq j \leq m_n} \sup_{x \in A_{nj}} |f((x_t + x)/h) - f((x_t + y_j)/h)|
\leq C(hn_n')^{-1} \sum_{t=1}^n |u_t|
\leq C(c_n \log n)^{1/2} \frac 1n \sum_{t=1}^n |u_t| = O((c_n \log n)^{1/2}), \quad \text{a.s.}
\] (4.2)

by the strong law of large number.

In order to investigate \( \lambda_{2n} \), write \( u'_t = u_t I[|u_t| \leq (c_n / \log n)^{1/2}] \) and \( u''_t = u'_t - E(u'_t \mid \mathcal{F}_{t-1}) \). Recalling \( E(u_t \mid \mathcal{F}_{t-1}) = 0 \) and \( \sup_x |f(x)| < \infty \), we have
\[
\lambda_{2n} \leq \max_{0 \leq j \leq m_n} \left| \sum_{t=1}^n u''_t f((x_t + y_j)/h) \right|
+ \max_{0 \leq j \leq m_n} \left| \sum_{t=1}^n |u_t - u''_t| + E(|u_t - u''_t| \mid \mathcal{F}_{t-1}) f((x_t + y_j)/h) \right|
\leq \max_{0 \leq j \leq m_n} \left| \sum_{t=1}^n u''_t f((x_t + y_j)/h) \right|
+ C \sum_{t=1}^n |u_t - u''_t| + E(|u_t - u''_t| \mid \mathcal{F}_{t-1})
:= \lambda_{3n} + \lambda_{4n}.
\] (4.3)
Routine calculations show that, under $\sup_{t \geq 1} E(|u_t|^{2p} | \mathcal{F}_{t-1}) < \infty$ and $n c_n^{-p} \log^{p-1} n = O(1)$,

$$\lambda_{4n} \leq \sum_{t=1}^{n} |u_t| I\{|u_t| > (c_n / \log n)^{1/2}\} + E(|u_t| I\{|u_t| > (c_n / \log n)^{1/2}\} | \mathcal{F}_{t-1})$$

$$\leq C \left( \frac{c_n}{\log n} \right)^{(1-2p)/2} \sum_{t=1}^{n} |u_t|^{2p} + E(|u_t|^{2p} | \mathcal{F}_{t-1})$$

$$\leq C(c_n \log n)^{1/2} \frac{1}{n} \sum_{t=1}^{n} |u_t|^{2p} + E(|u_t|^{2p} | \mathcal{F}_{t-1})$$

$$= O(\{c_n \log n\}^{1/2}), \quad \text{a.s.}$$

by the strong law of large number again.

We next consider $\lambda_{3n}$. As $E(|u_t|^2 | \mathcal{F}_{t-1}) \leq 2(E(|u_t|^2 | \mathcal{F}_{t-1}))^{1/p}$, a.s., Assumptions 2.1 and 2.3 imply that

$$\max_{0 \leq j \leq m_n} \sum_{t=1}^{n} f^2((x_t + y_j)/h) E(|u_t|^2 | \mathcal{F}_{t-1}) = O_P(c_n).$$

(4.5)

Hence, for any $\eta > 0$, there exists a $M_0 > 0$ such that

$$P\left( \max_{0 \leq j \leq m_n} \sum_{t=1}^{n} \sigma_{ij}^2 \geq M_0 c_n \right) \leq \eta,$$

where $\sigma_{ij}^2 = f^2((x_t + y_j)/h) E(|u_t|^2 | \mathcal{F}_{t-1})$, whenever $n$ is sufficiently large. This, together with $|u_t|^2 \leq 2(c_n / \log n)^{1/2}$ and the well-known martingale exponential inequality (see, e.g., de la Peña [6]), implies that, for any $\eta > 0$, there exists a $M_0 \geq 6d(k + 3)$ ($k$ is as in Assumption 2.3) such that, whenever $n$ is sufficiently large,

$$P[\lambda_{3n} \geq M_0(c_n \log n)^{1/2}]$$

$$\leq P\left[ \lambda_{3n} \geq M_0(c_n \log n)^{1/2}, \max_{0 \leq j \leq m_n} \sum_{t=1}^{n} \sigma_{ij}^2 \leq M_0 c_n \right] + \eta$$

$$\leq \sum_{j=0}^{m_n} P\left[ \sum_{t=1}^{n} u_t f([x_k + y_j]/h) \geq M_0(c_n \log n)^{1/2}, \sum_{t=1}^{n} \sigma_{ij}^2 \leq M_0 c_n \right] + \eta$$

$$\leq m_n \exp\left\{ - \frac{M_0^2 c_n \log n}{6 M_0 c_n} \right\} + \eta \leq m_n n^{-M_0/6} + \eta \leq 2\eta,$$

(4.6)

where we have used the following fact:

$$m_n \leq C\{n^{k+1} h^{-1}/(c_n \log n)^{1/2}\}^{d} \leq C_1 n^{(k+2)d}$$
as $c_n \to \infty$ and $nh \to \infty$. This yields $\lambda_{3n} = O_P[(c_n \log n)^{1/2}]$. Combining (4.1)–(4.6), we establish (2.2).

To prove (2.4), by checking (4.1)–(4.4), it suffices to show that
\[ \lambda_{3n} = O[(c_n \log n)^{1/2}], \quad \text{a.s.} \]  
under the alternative condition (2.3). In fact, as in (4.5), it follows from (2.3) that
\[ \max_{0 \leq j \leq m_n} \sum_{t=1}^{n} f^2((x_t + y_j)/h)E[(u_t^*)^2 | \mathcal{F}_{t-1}] = O(c_n), \quad \text{a.s.} \]
Similarly to proof of (4.6), we have for sufficiently large $M_0$ ($M_0 \geq 6d(k+4)$, say),
\[ P[\lambda_{3n} \geq M_0(c_n \log n)^{1/2}, \text{i.o.}] \]
\[ = P \left[ \lambda_{3n} \geq M_0(c_n \log n)^{1/2}, \max_{0 \leq j \leq m_n} \sum_{k=1}^{n} \sigma_k^2 \leq M_0c_n, \text{i.o.} \right] \]
\[ \leq \lim_{s \to \infty} \sum_{n=s}^{\infty} P \left[ \lambda_{3n} \geq M_0(c_n \log n)^{1/2}, \max_{0 \leq j \leq m_n} \sum_{k=1}^{n} \sigma_k^2 \leq M_0c_n \right] \]
\[ \leq \lim_{s \to \infty} \sum_{n=s}^{\infty} n^{(k+2)d_n} \frac{M_0^2c_n \log n}{6M_0c_n} \]
\[ \leq C \lim_{s \to \infty} \sum_{n=s}^{\infty} n^{(k+2)d_n-M_0/6} = 0, \]
which yields (4.7). The proof of Theorem 2.1 is now complete. \(\blacksquare\)

**Proof of Theorem 2.2.** We only prove (2.6). It is similar to prove (2.8) and hence the details are omitted. We may write
\[ \sum_{t=1}^{n} u_t f([x_t + x]/h) \]
\[ = \sum_{t=1}^{n} u_t f([x_t + x]/h)I(\|x_t\| \leq b_n/2) \]
\[ + \sum_{t=1}^{n} u_t f([x_t + x]/h)I(\|x_t\| > b_n/2) \]
\[ = \lambda_{5n}(x) + \lambda_{6n}(x) \quad \text{say.} \]
It is readily seen from (2.2) and $n \sup_{\|x\| > b_n/2} |f(x/h)| = O[(c_n \log n)^{1/2}]$ that
\[ \sup_{x \in R^d} |\lambda_{5n}(x)| \leq \sup_{\|x\| \leq b_n} |\lambda_{5n}(x)| + \sup_{\|x\| > b_n} |\lambda_{5n}(x)| \]
Q. Wang and N. Chan

\[ \leq O_P[(c_n \log n)^{1/2}] \]

\[ + \sup_{\|x\| > b_n/2} |f(x/h)| \sum_{t=1}^{n} |u_t| \]

\[ \leq O_P[(c_n \log n)^{1/2}] \]

as \( \frac{1}{n} \sum_{t=1}^{n} |u_t| = O(1) \), a.s. by the strong law. As for \( \lambda_{\delta n}(x) \), we have

\[ E \sup_{x \in \mathbb{R}^d} |\lambda_{\delta n}(x)| \leq C \sum_{t=1}^{n} E[|u_t| I(\|x_t\| > b_n/2)] \]

\[ \leq C \sum_{t=1}^{n} P(\|x_t\| > b_n/2) \leq Cb_n^{-k_0} \sum_{t=1}^{n} E\|x_t\|^{k_0} \]

\[ = O[(c_n \log n)^{1/2}], \]

which yield \( \sup_{x \in \mathbb{R}^d} |\lambda_{\delta n}(x)| = O_P[(c_n \log n)^{1/2}] \). Taking these estimates into (4.9), we obtain (2.6). The proof of Theorem 2.2 is complete. \( \square \)

**Proof of Theorem 2.3.** First, assume there exists a \( C \in \mathcal{E}^+ \) such that

\[ P(x, A) \geq bI_C(x)\nu(A), \quad x \in E, A \in \mathcal{E}, \]

for some \( b > 0 \) and probability measure \( \nu \) on \( (E, \mathcal{E}) \) with \( \nu(C) > 0 \). Under this addition assumption, Theorem 2.3 can be established by using the so-called split chain technique. To this end, define new random variables \( Y_0, Y_1, \ldots \) and \( \bar{x}_0, \bar{x}_1, \ldots \) by

\[ P(\bar{x}_0 \in A) = \nu(A), \]

\[ P(Y_n = 1 \mid \bar{x}_n = x) = h(x), \]

\[ P(Y_n = 0 \mid \bar{x}_n = x) = 1 - h(x), \]

\[ P(\bar{x}_{n+1} \in A \mid \bar{x}_n = x, Y_n = 1) = \nu(A), \]

\[ P(\bar{x}_{n+1} \in A \mid \bar{x}_n = x, Y_n = 0) = \frac{P(x, A) - h(x)\nu(A)}{1 - h(x)}, \]

where \( h(x) = bI_C(x) \). As easily seen, \( \{\bar{x}_n, Y_n\}_{n=0}^{\infty} \) is a Harris recurrent Markov chain with state space \( E \times \{0, 1\} \) and \( \{\bar{x}_n\}_{n=0}^{\infty} \) has the same transition probability \( P(x, A) \) as those of \( \{x_n\}_{n=0}^{\infty} \). Since our result is free of the initial distribution, \( \{x_n\}_{n=0}^{\infty} \) can be assumed to be identical with \( \{\bar{x}_n\}_{n=0}^{\infty} \), that is, \( x_0 \) has the distribution \( \nu \).

Further define \( \rho_0 = -1, \quad \rho_k = \min\{i : i \geq \rho_{k-1}, Y_i = 1\}, \quad k = 1, 2, \ldots, \)
Uniform convergence rates for a class of martingales

\[ N(n) = \max\{k: \rho_k \leq n\}, \]
and
\[ Z_j(x) = \sum_{k=\rho_{j-1}+1}^{\rho_j} f^2[(x_k + x)/h], \quad Z_{jn}(x) = \sum_{k=\rho_{j-1}+n+1}^{\rho_1 \wedge n} f^2[(x_k + x)/h] \]
for \( j = 1, 2, \ldots \). It is well known that the blocks
\[ (x_{\rho_i+1}, \ldots, x_{\rho_{i+1}}), \quad i = 0, 1, 2, \ldots, \]
are i.i.d. blocks, \( x_{\rho_i+1} \) having the distribution \( \nu \). Hence, for each \( h \) and \( x \), \( \{Z_j(x), \rho_j - \rho_{j-1}\}_{j=1}^{\infty} \), where \( Z_j^2(x) = Z_j(x) \) or \( Z_{jn}(x) \) is a sequence of i.i.d. random vectors. Furthermore, by recalling that \( \pi \) has a bounded density function \( p(s), \int_{-\infty}^{\infty} |f(x)| d\pi(x) < \infty \) and \( \sup_n |f(s)| < \infty \), we have
\[ \mathbb{E}Z_1(x) = b \int_{-\infty}^{\infty} f^2[(s + x)/h] \pi(ds) \]
for any \( x \in \mathbb{R} \) and
\[ \sup_{x \in \mathbb{R}} \mathbb{E}|Z_1(x)|^{2k} \leq Ch \]
for any integer \( k \). See Lemma 5.2 of Karlsen and Tjøstheim [14] or Lemma B.1 of Gao, Li and Tjøstheim [11]. We also have the following lemma.

**Lemma 4.1.** Suppose that \( d_n \sim C_0 a(n) \), where \( C_0 > 0 \) is a constant, and all \( y_j, j = 0, 1, \ldots, m_n \), are different, where \( |y_j| \leq n^{-m_0} \) and \( m_n \leq n^{m_1} \) for some \( m_0, m_1 > 0 \). Then,
\[ R_n := \max_{0 \leq j \leq m_n} \left| \sum_{k=0}^{d_n} [Z_k^*(y_j) - \mathbb{E}Z_k^*(y_j)] \right| = O_P[n^{-\varepsilon_0/4}a(n)h], \]
\[ \Delta_n := \max_{0 \leq j \leq m_n} \mathbb{E} \left| \sum_{k=0}^{d_n} [Z_k^*(y_j) - \mathbb{E}Z_k^*(y_j)] \right| = O[n^{-\varepsilon_0/4}a(n)h], \]
where \( \varepsilon_0 \) is a constant such that \( n^{-\varepsilon_0}a(n)h \rightarrow \infty \).

**Proof.** Only consider \( Z_k^*(x) = Z_k(x) \), as the situation that \( Z_k^*(x) = Z_{kn}(x) \) is similar. To this end, write \( \tilde{Z}_i(y_j) = Z_i(y_j)I(|Z_i(y_j)| \leq n^{-\varepsilon_0/2}a(n)h) \) and \( \tilde{Z}_i(y_j) = Z_i(y_j)I(|Z_i(y_j)| > n^{-\varepsilon_0/2}a(n)h) \). We have
\[ R_n \leq \max_{0 \leq j \leq m_n} \left| \sum_{i=1}^{d_n} [\tilde{Z}_i(y_j) - \mathbb{E}\tilde{Z}_i(y_j)] \right| + \max_{0 \leq j \leq m_n} \sum_{i=1}^{d_n} [\tilde{Z}_i(y_j) + \mathbb{E}\tilde{Z}_i(y_j)] \]
\[4.12\]

By taking \(k \geq (m_1 + 2)/\varepsilon_0\) in (4.12) and noting \(n^{-\varepsilon_0}a(n)h \to \infty\), simple calculations show that

\[
ER_{2n} \leq Cm_n a(n) \max_{0 \leq j \leq m_n} EZ_1(y_j)I(|Z_i(y_j)| > n^{-\varepsilon_0/2}a(n)h)
\]

\[
\leq C_1 a(n)h(n^{m_1+1-k\varepsilon_0}h^{-1}) \leq C_1 a(n)h(nh)^{-1}
\]

\[\leq C_2 n^{-\varepsilon_0/2}a(n)h,
\]

which yields \(R_{2n} = O_p[n^{-\varepsilon_0/2}a(n)h]\). As for \(R_{1n}\), by using (4.12) with \(k = 2\) and noting

\[
Ee^{t(\tilde{Z}_i(y_j) - E\tilde{Z}_i(y_j))} \leq 1 + \frac{t^2}{2} E\tilde{Z}_i^2(y_j)e^{2n^{-\varepsilon_0/2}a(n)h} \leq e^{C_0 t^2 h}
\]

for any \(t \leq (n^{-\varepsilon_0/2}a(n)h)^{-1}\) and some \(C_0 > 0\), the standard Markov inequality implies that

\[
P(R_{1n} \geq Mn^{-\varepsilon_0/4}a(n)h)
\]

\[
\leq Cm_n \max_{0 \leq j \leq m_n} P\left(\sum_{i=1}^{C_2 a(n)} |\tilde{Z}_i(y_j) - E\tilde{Z}_i(y_j)| \geq Mn^{-\varepsilon_0/4}a(n)h\right)
\]

\[\leq Cm_n \exp\left(-Mt n^{-\varepsilon_0/4}a(n)h + C_2 a(n)t^2 h\right)
\]

\[\leq Cm_n \exp\left(-Mt n^{-\varepsilon_0/4}a(n)h\right) \to 0
\]

as \(n \to \infty\). Hence, \(R_{1n} = O_p[n^{-\varepsilon_0/4}a(n)h]\). Combining (4.15)–(4.17), we prove (4.13).

The proof of (4.14) is similar except more simpler. Indeed, by independence of \(\tilde{Z}_i(x)\), we obtain

\[
\Delta_n \leq \max_{0 \leq j \leq m_n} E\left[\sum_{i=1}^{d_n} |\tilde{Z}_i(y_j) - E\tilde{Z}_i(y_j)|\right]
\]

\[
+ 2 \max_{0 \leq j \leq m_n} \sum_{i=1}^{d_n} E\tilde{Z}_i(y_j)
\]

\[
\leq 2 \max_{0 \leq j \leq m_n} d_n^{1/2}[E\tilde{Z}_i^2(y_j)]^{1/2} + Cn^{-\varepsilon_0/2}a(n)h
\]

\[\leq Cn^{-\varepsilon_0/4}a(n)h,
\]

due to the fact:

\[
E\tilde{Z}_i^2(y_j) \leq n^{-\varepsilon_0/2}a(n)h Z_1(y_j) \leq Cn^{-\varepsilon_0/2}a(n)h^2.
\]

The proof of Lemma 4.1 is complete. \(\square\)
Uniform convergence rates for a class of martingales

We are now ready to prove (2.19) and (2.21) under the additional condition (4.10). (2.19) first. As in proof of (4.1) and (4.2), but letting \( y_j = -\lfloor n^m \rfloor - 1 + j/m'_n, j = 0, 1, 2, \ldots, m_n \), where \( m'_n = \lfloor nh^{-2}/a(n) \rfloor \) and \( m_n = 2(\lfloor n^m \rfloor + 1)m'_n \), we have

\[
\sup_{|x| \leq n^m} \sum_{k=0}^{n} f^2[(x_k + x)/h] \leq \max_{0 \leq j \leq m_n} \sum_{k=0}^{n} f^2[(x_k + y_j)/h] + Ca(n)h. \tag{4.18}
\]

Note that

\[
\sum_{k=0}^{n} f^2[(x_k + x)/h] \leq \sum_{k=0}^{\rho_n(n+1)} f^2[(x_k + x)/h] = \sum_{i=1}^{N(n+1)} Z_i(x),
\]

and \( \{N(n)/a(n)\}_{n \geq 1} \) is bounded in probability. See, for example, Chen [5]. For each \( \varepsilon > 0 \), there exist \( 0 < C_\varepsilon, C_{1\varepsilon} < \infty \) such that

\[
P(C_{1\varepsilon}a(n) \leq N(n) \leq C_{\varepsilon}a(n)) \geq 1 - \varepsilon, \tag{4.19}
\]

whenever \( n \) is sufficiently large. Consequently, for each \( a > 0, \varepsilon > 0 \) and \( n \) large enough,

\[
P \left( \max_{0 \leq j \leq m_n} \sum_{k=0}^{n} f^2[(x_k + y_j)/h] \geq a \right) \leq P \left( \max_{0 \leq j \leq m_n} \sum_{i=1}^{C_{\varepsilon}a(n)} Z_i(y_j) \geq a \right) + \varepsilon.
\]

This, together with (4.13) with \( Z_k(x) = Z_k(x) \), implies (2.19) under (4.10), since

\[
\max_{0 \leq j \leq m_n} \sum_{i=1}^{C_{\varepsilon}a(n)} Z_i(y_j) \leq C_{\varepsilon}a(n) \max_{0 \leq j \leq m_n} EZ_1(y_j) + R_n = O_P[a(n)h].
\]

We next consider (2.21) under (4.10). To this regard, let \( y_j = -\lfloor b_n \rfloor - 1 + j/m'_n, j = 0, 1, 2, \ldots, m_n \), where \( m'_n = \lfloor n^{1+\varepsilon_0}/2h^{-2}/a(n) \rfloor \) and \( m_n = 2(\lfloor b_n \rfloor + 1)m'_n \). Since

\[
\max_{0 \leq j \leq m_n - 1} \sup_{0 \leq x \leq b_n} \sum_{i=1}^{n} \left| f^2[(x_i + x)/h] - f^2[(x_i + y_j)/h] \right| 
\]

\[
\leq Cnh^{-1} \max_{0 \leq j \leq m_n - 1} |y_{j+1} - y_j| \leq Cn^{-\varepsilon_0/2}a(n)h,
\]

it is readily seen that

\[
\inf_{|x| \leq b_n} \sum_{t=1}^{n} f^2[(x_t + x)/h] \geq \Delta_{1n} - O_P[n^{-\varepsilon_0/2}a(n)h], \tag{4.20}
\]

where \( \Delta_{1n} = \inf_{1 \leq j \leq m_n} \sum_{t=1}^{n} f^2[(x_t + y_j)/h] \). Furthermore, by recalling (4.19) and noting that

\[
\sum_{k=0}^{n} f^2[(x_k + x)/h] \geq \sum_{k=0}^{\rho_n(n)\wedge n} f^2[(x_k + x)/h] = \sum_{i=1}^{N(n)} Z_{in}(x),
\]

we have
we have, for each $a > 0, \varepsilon > 0$ and $n$ large enough,

$$P(\Delta_1 \geq a) \geq P\left(\inf_{0 \leq j \leq m_n} \sum_{i=1}^{C_1 a(n)} Z_{in}(y_j) \geq a\right) - \varepsilon. \quad (4.21)$$

On the other hand, it follows from (4.13) with $Z_k(x) = Z_{kn}(x)$ that

$$\inf_{0 \leq j \leq m_n} \sum_{i=1}^{C_1 a(n)} Z_{in}(y_j) \geq C_1 a(n) \inf_{0 \leq j \leq m_n} E Z_{1n}(y_j) - R_n \geq C_1 a(n) \inf_{0 \leq j \leq m_n} E Z_{1n}(y_j) - O_P[n^{-\varepsilon_0/4} a(n) h]. \quad (4.22)$$

Combining (4.20)–(4.22), the result (2.21) under (4.10) will follow if we prove: there exists a $b_0 > 0$ such that

$$\inf_{0 \leq j \leq m_n} E Z_{1n}(y_j) \geq b_0 h \quad (4.23)$$

for all $n$ sufficiently large. To prove (4.23), first note that there exists a $b_1 > 0$ such that $E N^2(n)/a^2(n) \leq b_1$. See Lemma 3.3 of Karlsen and Tjøstheim [14], for instance. Therefore, by taking $d_n = \lfloor b_2 a(n) \rfloor + 1$, where $b_2 > b_1$ is chosen later, we have for some $b_0 > 0$,

$$\inf_{0 \leq j \leq m_n} E Z_{1n}(y_j) = \frac{1}{d_n} \inf_{0 \leq j \leq m_n} E \sum_{t=1}^{d_n} Z_{in}(y_j)$$

$$= \frac{1}{d_n} \inf_{0 \leq j \leq m_n} E \sum_{t=1}^{\rho_{d_n} \wedge n} f^2([x_t + y_j]/h)$$

$$\geq \frac{1}{d_n} \inf_{0 \leq j \leq m_n} E \left(\sum_{t=1}^{n} f^2([x_t + y_j]/h) - I(\rho_{d_n} \leq n) \sum_{t=1}^{\rho_{d_n}} f^2([x_t + y_j]/h)\right)$$

$$\geq \frac{1}{d_n} \left(\inf_{|x| \leq b_n + 1} E \sum_{k=1}^{n} f^2([x_t + x]/h) - M_n\right)$$

$$\geq \frac{1}{d_n} [a(n) h/C_0 - M_n]$$

$$\geq b_0 h,$$

whenever $n$ is sufficiently large, where we have used the condition (2.20) and the fact: it follows from (4.11), (4.14) and $\rho_{d_n} \leq n$ if and only if $N(n) > d_n$ that

$$M_n := \max_{0 \leq j \leq m_n} E \left[I(\rho_{d_n} \leq n) \sum_{t=1}^{\rho_{d_n}} f^2([x_t + y_j]/h)\right]$$

$$\leq \frac{1}{d_n} [a(n) h/C_0 - M_n]$$

$$\geq b_0 h,$$
Uniform convergence rates for a class of martingales

\[ = \max_{0 \leq j \leq m_n} E \left[ I(\rho_{d_n} \leq n) \sum_{i=1}^{d_n} Z_i(y_j) \right] \]

\[ \leq d_n \max_{0 \leq j \leq m_n} EZ_1(y_j)P(N(n) \geq d_n) + \max_{0 \leq j \leq m_n} E \left[ \sum_{i=1}^{d_n} [Z_i(y_j) - EZ_i(y_j)] \right] \]

\[ \leq b_2^{-1} C^* h a^{-1}(n) EN^2(n) + O[n^{-\varepsilon_0/4} a(n) h] \]

\[ \leq C_0^{-1} a(n) h/2 \]

by choosing \( b_2 = 3C_0 b_1 C^* \) and \( n \) sufficiently large. This proves (4.23) and also completes the proof of (2.21) under (4.10).

We now consider general situation. Let \( 0 < t < 1 \) be fixed. Define a transition probability \( P_t(x, A) \) on \((E, \mathcal{E})\) by

\[ P_t(x, A) = (1 - t) \sum_{k=1}^{\infty} t^{k-1} P^k(x, A), \quad x \in E, A \in \mathcal{E}. \]

Let \( \{\beta_n\}_{n \geq 1} \) be an i.i.d. Bernoulli random variables with the common law

\[ P(\beta_1 = 0) = t \quad \text{and} \quad P(\beta_1 = 1) = 1 - t \]

and assume \( \{\beta_n\}_{n \geq 1} \) and \( \{x_n\}_{n \geq 0} \) are independent. Define a renewal sequence \( \{\sigma(k)\}_{k \geq 0} \) by

\[ \sigma(0) = 0 \quad \text{and} \quad \sigma(k) = \inf\{n : n \geq \sigma(k-1); \beta_n = 0\}, \quad k \geq 1. \]

With these notations, \( \{x_{\sigma(n)}\}_{n \geq 0} \) is a Harris recurrent Markov chain with the invariant measure \( \pi \). The transition probability \( P_t(x, A) \) of \( \{x_{\sigma(n)}\}_{n \geq 0} \) satisfies the additional condition (4.10) and

\[ a_t(n) := \pi(D)^{-1} \sum_{k=1}^{n} \nu P_k(D) \sim (1 - t)^{1-\gamma} a(n). \]

See Chen [5], for instance. By virtue of these facts, it follows from the first part proof of (2.19) that, for any fixed \( m > 0 \) and \( h > 0 \),

\[ \sup_{|x| \leq n^m} \sum_{k=1}^{\sigma(n)} \beta_k f^2[(x_k + x)/h] = \sup_{|x| \leq n^m} \sum_{k=1}^{n} f^2[(x_{\sigma(k)} + x)/h] = O_P[a_t(n) h]. \]

Now by noting \( \sigma([\lambda n])/n \to_{\lambda_n} \lambda/(1 - t) \) by the strong law and taking \( \lambda \) such that \( \lambda/(1 - t) \geq 1 \), simple calculations show that

\[ \sup_{|x| \leq n^m} \sum_{k=1}^{n} \beta_k f^2[(x_k + x)/h] \leq \sup_{|x| \leq n^m} \sum_{k=1}^{\sigma([\lambda n])} f^2[(x_{\sigma(k)} + x)/h] = O_P[a(n) h]. \]
Similarly,
\[
\sup_{|x| \leq n \sqrt{n}} \sum_{k=1}^{n} (1 - \beta_k) f^2[(x_k + x)/h] = O_P[a(n)h]
\]
and hence the result (2.19) under general situation follows.

The proof of (2.21) under general situation is similar and hence the details are omitted. □

Proof of Corollary 2.1. We first notice that:

\begin{enumerate}
\item[(F)] $x_k = \sum_{j=1}^{k} \varepsilon_j$ is a Harris null recurrent Markov chain, satisfying (4.10), $a(t) = \sqrt{t}$ and the invariant measure $\pi$ is the Lebesgue measure.
\end{enumerate}

Due to the fact (F), (2.23) follows immediately from Theorem 2.3.

To prove (2.24), by Theorem 2.3, it suffices to show that (2.20) holds true with $b_n = \tau_n \sqrt{n}$ and $a(n) = \sqrt{n}$. In fact, under the conditions of Corollary 2.1, $x_k/\sqrt{k}$ has a density $p_k(x)$, satisfying $\sup_x p_k(x) = 0$, as $k \to \infty$, where $\phi(x) = e^{-x^2/2}/\sqrt{2\pi}$, due to the central limit theorem. This implies that

\[
\inf_{|x| \leq 3\tau_n} p_k(x) \geq \inf_{|x| \leq 3\tau_n} \phi(x) - \sup_x |p_k(x) - \phi(x)| \geq A_0 > 0
\]

for some $A_0 > 0$ and all sufficiently large $k$. Hence, for $n/2 < k \leq n$ and $n$ sufficiently large, we have

\[
\inf_{|x| \leq \tau_n \sqrt{n} + 1} E f^2[(x_k + x)/h] = \inf_{|x| \leq \tau_n \sqrt{n} + 1} \int_{-\infty}^{\infty} f^2[(\sqrt{k}y + x)/h] p_k(y) \, dy
\]

\[
\geq \frac{h}{\sqrt{k}} \inf_{|x| \leq \tau_n \sqrt{n} + 1} \int_{-\infty}^{\infty} f^2(y) p_k(\sqrt{k}y - x) \, dy
\]

\[
\geq \frac{h}{\sqrt{k}} \inf_{|x| \leq \tau_n} p_k(x) \int_{|y| \leq M_1} f^2(y) \, dy
\]

\[
\geq \frac{A_0 h}{2\sqrt{n}} \int_{|y| \leq M_1} f^2(y) \, dy,
\]

where $M_1$ is chosen such that $\int_{|y| \leq M_1} f^2(y) \, dy > 0$. Consequently, there exists a constant $C_0 > 0$ such that

\[
\inf_{|x| \leq \tau_n \sqrt{n} + 1} \sum_{k=1}^{n} E f^2[(x_k + x)/h] \geq \inf_{|x| \leq \tau_n \sqrt{n} + 1} \sum_{k=n/2}^{n} E f^2[(x_k + x)/h] \geq \sqrt{n}h/C_0
\]

as required. The proof of Corollary 2.1 is now complete. □
Uniform convergence rates for a class of martingales

Proof of Theorem 3.1. We may write $\hat{m}(x) - m(x)$ as

$$
\hat{m}(x) - m(x) = \frac{\sum_{t=1}^{n} u_t K_h(x_t - x)}{\sum_{t=1}^{n} K_h(x_t - x)} + \frac{\sum_{t=1}^{n} [m(x_t) - m(x)] K_h(x_t - x)}{\sum_{t=1}^{n} K_h(x_t - x)}
$$

$$
:= \Theta_{1n}(x) + \Theta_{2n}(x).
$$

Note that, for any $|x| \leq b_n'$, there exists a $C_0 > 0$ such that $K[(x_t - x)/h] = 0$ if $|x_t - x| \geq hC_0$. It follows from Assumption 3.3 that, whenever $n$ is sufficiently large,

$$
\sup_{|x| \leq b_n'} |\Theta_{2n}(x)| \leq C_1 \delta_n \sup_{|x| \leq b_n'} \frac{\sum_{t=1}^{n} |x_t - x|^\alpha K[(x_t - x)/h]}{\sum_{t=1}^{n} K[(x_t - x)/h]} \leq Ch^\alpha \delta_n.
$$

This, together with (2.21) [taking $f^2(s) = K(s)$] in Theorem 2.3, implies that (3.3) will follow if we prove

$$
\sup_{|x| \leq b_n'} \sum_{t=1}^{n} u_t K[(x_t - x)/h] = O_P[\delta_n h^{1/2} \log^{1/2} n].
$$

(4.25)

In fact, with $p \geq 1 + 1/\varepsilon_0$ and $c_n = a(n)h \to \infty$, we have

$$
n c_n^{-p} \log^{p-1} n \leq (n^{-\varepsilon_0} a(n)h)^{-1-1/\varepsilon_0} n^{-\varepsilon_0} \log^{p-1} n \to 0,
$$

since $n^{-\varepsilon_0} a(n)h \to \infty$. Now, by recalling (2.19), it is readily seen that the conditions of Theorem 2.1 hold for $f(x) = K(x)$ and $c_n = a(n)h$. The result (4.25) follows from (2.2) in Theorem 2.1.
