Quantum Orthogonal Cayley-Klein Groups
In Cartesian Basis

Abstract

The similarity transformations of quantum orthogonal groups are developed and FRT theory is reformulated to the Cartesian basis. The quantum orthogonal Cayley-Klein groups are introduced as the algebra functions over an associative algebra with the nilpotent generators. The quantum orthogonal Cayley-Klein algebras are obtained as the dual objects to the corresponding quantum groups.

1 Introduction

The simple quantum groups and algebras are described by FRT theory. Although the quantum group as a mathematical structure is not a group at all but it is a Hopf algebra, nevertheless there are many parallel features for both group and quantum group.

In group theory there is a remarkable set of groups, namely the motion groups of $3^n$ $n$-dimensional spaces of constant curvature or the orthogonal Cayley-Klein (CK) groups. The classical simple orthogonal groups $SO(n)$, the semisimple pseudoorthogonal groups $SO(p,q)$ and non-semisimple groups such as Euclidean $E(n)$, Poincare $P(n)$, Galileian $G(n)$ are in this set. The nonsemisimple groups may be obtained from the simple (or semisimple) one’s by the well known procedure of contraction. On the other hand the set of CK groups may be described in uniform manner with the help of pure algebrical methods.

In the present paper we apply this approach for description of quantum (nonsemisimple) orthogonal CK groups and corresponding quantum algebras. As it turned out slightly modified FRT theory is suitable for this purpose: it is enough to replace the complex number field $\mathbb{C}$ by the dual algebra $D_n(\iota; \mathbb{C})$ with the nilpotent generators.

The contents of this work is as follows. The dual algebra $D_n(\iota; \mathbb{C})$ is briefly described in Sec.2. The linear transformations of generators of
quantum orthogonal group are regarded in Sec.3 and the description of $SO_q(N; C)$ is given. In Sec.4 the quantum Cayley-Klein groups $SO_q(N; j)$ are introduced as Hopf algebra of the noncommutative functions with dual variables. Quantum Cayley-Klein algebra $so_q(N; j)$ are considered in Sec.5 as the dual object to the $SO_q(N; j)$. The developed theory is illustrated by the $N=3$ example of quantum group and algebra in Sec.6.

2 Dual algebra $D_n(t; C)$

Dual algebra $D_n(t; C)$ is defined as an associative algebra with unit and nilpotent generators $t_1, \ldots, t_n$, $t_k^2 = 0$, $k = 1, \ldots, n$ with commutative multiplication $t_k t_m = t_m t_k$, $k \neq m$. The general element of $D_n(t; C)$ has the form

$$a = a_0 + \sum_{p=1}^{n-1} \sum_{k_1 < \ldots < k_p} a_{k_1 \ldots k_p} t_{k_1} \cdots t_{k_p}, \quad a_0, a_{k_1 \ldots k_p} \in C. \quad (1)$$

For $n = 1$ we have $D_1(t_1; C) \cong C = a_0 + a_1 t_1$, i.e. dual (or Study) numbers, when $a_0, a_1 \in R$. For $n = 2$ the general element of $D_2(t_1, t_2; C)$ is written as follows: $a = a_0 + a_1 t_1 + a_2 t_2 + a_{12} t_1 t_2$.

Divisions $a/t_k, a \in R, C$, and $t_m / t_k, k \neq m$ are not defined, but division of a dual unit by itself is equal to real unit $t_k / t_k = 1$. A function of a dual argument is defined by its Taylor expansion $f(x_0 + t_k x_1) = f(x_0) + t_k x_1 f'(x_0)$.

The well known Grassmann algebra $\Gamma_n(\xi)$ is the algebra with nilpotent generators $\xi_1^2 = 0, k = 1, \ldots, n$ and anticommutative multiplication $\xi_k \xi_m = -\xi_m \xi_k, k \neq m$. It is easy to verify that the product of two generators of Grassmann algebra has the same algebraic properties as the generator of dual algebra $t_k = \xi_k \xi_{n+k}, k = 1, \ldots, n$. This means that the dual algebra is the subalgebra of even part of Grassmann algebra $D_n(t; C) \subset \Gamma_{2n}(\xi)$.

3 Cartesian basis for $SO_q(N; C)$

According with FRT theory of quantum groups let us regard an algebra $C(t_{ik})$ of noncommutative polynomials of $N^2$ variables $t_{ik}, i, k = 1, \ldots, N$ over complex number field $C$. For well known lower triangular matrix $R_q \in M_{N^2}(C)$ the generators $T = (t_{ik})_{i,k=1}^{N} \in M_N(C(t_{ik}))$ have the following commutation relations

$$RT_1 T_2 = T_2 T_1 R, \quad (2)$$

where $T_1 = T \otimes I$, $T_2 = I \otimes T \in M_{N^2}(C(t_{ij}))$. There are additional relations of $q$-orthogonality $TCT^t = T^t C T = C$, \quad (3)

where $C = C_0 q^\rho, \rho = \text{diag}(\rho_1, \ldots, \rho_N)$, $$(\rho_1, \ldots, \rho_N) = \begin{cases} (n - \frac{1}{2}, n - \frac{3}{2}, \ldots, \frac{3}{2}, 0, -\frac{1}{2}, \ldots, -n + \frac{1}{2}), & \text{for } N = 2n + 1 \\ (n - 1, n - 2, \ldots, 1, 0, 0, -1, \ldots, -n + 1), & \text{for } N = 2n. \end{cases} \quad (4)$$
and the only nonzero elements of matrix $C_0 \in M_N(\mathbb{C})$ are real units on the second diagonal $(C_0)_{ik} = \delta_{i',k'} = N + 1 - i$. The quantum orthogonal group $SO_q(N; \mathbb{C})$ is defined as the quotient

$$SO_q(N; \mathbb{C}) = C\langle t_{ik} \rangle / (2), (3).$$

From the algebraic point of view $SO_q(N; \mathbb{C})$ is a Hopf algebra with the following coproduct $\Delta$, counit $\epsilon$ and antipode $S$:

$$\Delta T = T \otimes T, \quad \epsilon(T) = I, \quad S(T) = CT^t C^{-1}.$$ (6)

For $q = 1$ Eq.(3) is the orthogonality condition written with the help of matrix $C_0$ and the set of matrices $T$ is the orthogonal group $SO(N; \mathbb{C})$ in so-called "symplectic" basis. We shall call $SO_q(N; \mathbb{C})$ described by Eqs.(2)–(5) as the orthogonal quantum group in symplectic basis.

One of the solutions of matrix equation

$$DC_0D^t = I,$$ (7)

have the form

$$D = \frac{1}{\sqrt{2}} \begin{pmatrix} I & \tilde{C}_0 \\ i\tilde{C}_0 & -iI \end{pmatrix}, \quad N = 2n,$$ (8)

$$D = \frac{1}{\sqrt{2}} \begin{pmatrix} I & 0 & \tilde{C}_0 \\ 0 & \sqrt{2} & 0 \\ i\tilde{C}_0 & 0 & -iI \end{pmatrix}, \quad N = 2n + 1,$$ (8)

where $\tilde{C}_0 \in M_n(\mathbb{C})$ is the matrix with the real units on the second diagonal. For the nondeformed case $q = 1$ the equation

$$U = DT D^t$$ (9)

define the similarity transformation of the orthogonal matrix from symplectic to Cartesian basis. So we shall call the linear transformation (9) of generators of quantum group $SO_q(N; \mathbb{C})$ as transformation to the Cartesian basis.

It is easy to reformulate Eqs.(3)–(5) to the new basis. Commutation relations of Cartesian (or rotation) generators $U = (u_{ik})^N_{i,k=1} \in M_N(C(u_{ik}))$ are given by

$$\tilde{R}_q U_1 U_2 = U_2 U_1 \tilde{R}_q,$$ (10)

where

$$\tilde{R}_q = (D \otimes D) R_q (D \otimes D)^{-1}$$ (11)

is now the nontriangular matrix. The additional relations of $q$-orthogonality are as follows

$$UC'U^t = C', \quad U^t (C')^{-1} U = (C')^{-1},$$ (12)

where

$$C' = DCD^t = \begin{pmatrix} \cosh z \tilde{\rho} & 0 & i \sinh z \tilde{\rho} \\ 0 & 1 & 0 \\ -i\tilde{C}_0 \sinh z \tilde{\rho} & 0 & \tilde{C}_0 \cosh z \tilde{\rho} \end{pmatrix},$$ (13)

$\tilde{\rho} = \text{diag}(\rho_1, \ldots, \rho_n) \in M_n(\mathbb{C})$, for $N = 2n+1$ and without middle column and row for $N = 2n$. 3
The orthogonal quantum group $SO_q(N; C)$ in Cartesian basis is described by the quotient

$$SO_q(N; C) = C\langle u_{ik} \rangle / (10), (12), (14)$$

and is Hopf algebra with the following coproduct $\Delta$, counit $\epsilon$ and antipode $S$:

$$\Delta U = U \hat{\otimes} U, \quad \epsilon(U) = I, \quad S(U) = C^u U^i (C')^{-1}.$$ (15)

4 Quantum CK groups $SO_v(N; j)$ as matrix groups over dual algebras $D_{N-1}(t)$.

Orthogonal Cayley-Klein (CK) groups $SO(N; j)$ (or motion groups of spaces of constant curvature) are realized in the Cartesian basis as the matrix groups over $D_{N-1}(t)$ with the help of the special matrices

$$(A(j))_{kp} = \tilde{J}_{kp} a_{kp}, \quad a_{kp} \in C,$$

$$\tilde{J}_{kp} = J_{kp}, \quad k < p, \quad \tilde{J}_{kp} = J_{pk}, \quad k \geq p, \quad J_{\mu\nu} = \prod_{r=\mu}^{\nu-1} j_r, \quad \mu < \nu, \quad j_r = 1, \epsilon_r, \iota.$$

These matrices are satisfied the following $j$-orthogonality relations:

$$A(j) A^t(j) = A^t(j) A(j) = I.$$ (17)

In the symplectic basis the orthogonal CK groups are described by the matrices

$$B(j) = D^{-1} A(j) D$$

with the additional relations of $j$-orthogonality

$$B(j) C_0 B^t(j) = B^t(j) C_0 B(j) = C_0.$$ (19)

The matrix $D$ in Eqs.(18) is given by Eqs.(8).

For example matrices from CK group $SO(3; j)$ in Cartesian basis are

$$A(j) = \begin{pmatrix} a_{11} & j_1 a_{12} & j_1 j_2 a_{13} \\ j_1 a_{21} & a_{22} & j_2 a_{23} \\ j_1 j_2 a_{31} & j_2 a_{32} & a_{33} \end{pmatrix}$$

and in symplectic basis are

$$B(j) = \begin{pmatrix} b_{11} + ij_1 j_2 \tilde{b}_{11} & j_1 b_{12} - ij_2 \tilde{b}_{12} & b_{13} - ij_1 j_2 \tilde{b}_{13} \\ j_1 b_{21} + ij_2 b_{21} & b_{22} & j_2 b_{21} - ij_1 j_2 b_{21} \\ b_{13} + ij_1 j_2 \tilde{b}_{13} & j_1 b_{12} + ij_2 \tilde{b}_{12} & b_{11} - ij_1 j_2 \tilde{b}_{11} \end{pmatrix}.$$ (21)

We shall regard the quantum deformations of the contracted CK groups, i.e. $j_k = 1, \epsilon_k$. We shall follow to FRT theory, but instead of the algebra $C(t_{ik})$ our starting point is $D(t_{ik})$ — the algebra of noncommutative polynomials of $N^2$ variables $t_{ik}, \ i, k = 1, \ldots, N$ over dual algebra $D_{N-1}(t)$.

In addition we shall transform the deformation parameter $q = \exp z$ as follows:

$$z = Jv, \quad J \equiv J_{1N} = \prod_{k=1}^{N-1} j_k.$$ (22)
where \( v \) is the new deformation parameter.

In symplectic basis the quantum CK group \( SO_v(N; j) \) is produced by the generating matrix \( T(j) \in M_N(D(t_{ik})) \) equal to \( B(j) \) for \( q = 1 \). The noncommutative entries of \( T(j) \) obey the commutation relations
\[
R_v(j)T_1(j)T_2(j) = T_2(j)T_1(j)R_v(j),
\]
and the additional relations of \( (v, j) \)-orthogonality
\[
T(j)C(j)T^i(j) = T^i(j)C(j)T(j) = C(j),
\]
where lower triangular R–matrix \( R_v(j) \) and \( C(j) \) are obtained from \( R_q \) and \( C \), respectively, by substitution \( Jv \) instead of \( z \):
\[
R_v(j) = R_q(z \rightarrow Jv), \quad C(j) = C(z \rightarrow Jv).
\]

Then the quotient
\[
SO_v(N; j) = D \langle t_{ik} \rangle / (23),
\]
is Hopf algebra with the coproduct \( \Delta \), counit \( \epsilon \) and antipode \( S \):
\[
\Delta T(j) = T(j) \hat{\otimes} T(j), \quad \epsilon(T(j)) = I, \quad S(T(j)) = C(j)T^i(j)C^{-1}(j).
\]

In Cartesian basis the quantum CK group \( SO_v(N; j) \) is generated by \( U(j) = (J_{ik} u_{ik}) \in M_N(D(u_{ik})) \) with the commutation relations
\[
\tilde{R}_v(j) U_1(j) U_2(j) = U_2(j) U_1(j) \tilde{R}_v(j)
\]
and additional relations of \( (v, j) \)-orthogonality
\[
U(j) C'(j) U^i(j) = C'(j), \quad U^i(j)(C'(j))^{-1} U(j) = (C'(j))^{-1},
\]
where
\[
\tilde{R}_v(j) = \tilde{R}_q(z \rightarrow Jv), \quad C'(j) = C'(z \rightarrow Jv).
\]
The quotient
\[
SO_v(N; j) = D \langle u_{ik} \rangle / (28),
\]
is Hopf algebra with the following coproduct \( \Delta \), counit \( \epsilon \) and antipode \( S \):
\[
\Delta U(j) = U(j) \hat{\otimes} U(j), \quad \epsilon(U(j)) = I, \quad S(U(j)) = C'(j)U^i(j)(C'(j))^{-1}.
\]

5 Quantum CK algebras \( so_v(N; j) \) as a dual to \( SO_v(N; j) \).

According to FRT theory the dual space \( \text{Hom}(SO_v(N; j), \mathbb{C}) \) is an algebra with the multiplication induced by coproduct \( \Delta \) in \( SO_v(N; j) \)
\[
l_1 l_2(a) = (l_1 \otimes l_2)(\Delta(a)),
\]
where \( l_1, l_2 \in \text{Hom}(SO_v(N; j), \mathbb{C}) \) and \( a \in SO_v(N; j) \). Let us formally introduce \( N \times N \) upper (+) and lower (−) triangular matrices \( L^{(\pm)}(j) \) as follows: it is necessary to put \( j_k^{-1} \) in the nondiagonal matrix elements of \( L^{(\pm)}(j) \), if
there is the parameter $j_k$ in the corresponding matrix element of $T(j)$. For example, if $(T(j))_{12} = j_1t_{12} + j_2t_{12}$, then $(L^{(\pm)}(j))_{12} = j_1^{-1}t_{12} + j_2^{-1}t_{12}$. Formally the matrices $L^{(\pm)}(j)$ are not defined for $j_k = \epsilon_k$, since $\epsilon_k^{-1}$ do not exist, but if we give an action of the matrix functionals $j$ then we shall have well defined expressions even for dual values of the elements of $SO_v(N; j)$ by the duality relation

$$\langle L^{(\pm)}(j), T(j) \rangle = R^{(\pm)}(j),$$

where

$$R^{(+)}(j) = PR_v(j)P, \quad R^{(-)}(j) = R_v^{-1}(j), \quad Pu \otimes w = w \otimes u,$$

then we shall have well defined expressions even for dual values of the parameters $j_k$.

The elements of $L^{(\pm)}(j)$ satisfy the commutation relations

$$R^{(+)}(j)L^{(\sigma)}(j)L^{(\sigma)}(j) = L^{(\sigma)}(j)L^{(\sigma)}(j)R^{(+)}(j),$$

$$R^{(-)}(j)L^{(+)}(j)L^{(-)}(j) = L^{(-)}(j)L^{(-)}(j)R^{(+)}(j), \quad \sigma = \pm$$

and additional relations

$$L^{(\pm)}(j)C^\sigma(j)L^{(\pm)}(j) = C^\sigma(j),$$

$$L^{(\pm)}(j)(C^\sigma(j))^{-1}L^{(\pm)}(j) = (C^\sigma(j))^{-1},$$

$$t^{(+)}_{kk}(l_{kk}^{(\pm)} - l_{kk}^{(-)} = 1, \quad l_{11}^{(+)} \ldots l_{NN}^{(+)} = 1, \quad k = 1, \ldots, N.$$

An algebra $so_v(N; j) = \{I, L^{(\pm)}(j)\}$ is called quantum CK algebra and is Hopf algebra with the following coproduct $\Delta$, counit $\epsilon$ and antipode $S$:

$$\Delta L^{(\pm)}(j) = L^{(\pm)}(j) \otimes L^{(\pm)}(j), \quad \epsilon(L^{(\pm)}(j)) = I,$$

$$S(L^{(\pm)}(j)) = C^\sigma(j)(L^{(\pm)}(j))S(C^\sigma(j))^{-1}.$$

It is possible to show that algebra $so_v(N; j)$ is isomorphic with the quantum deformation of the universal enveloping algebra of the CK algebra $so(N; j)$, which may be obtained from the orthogonal algebra $so(N)$ by contractions. So there are at least two ways for construction of quantum CK algebras.

6 Example: $SO_v(3; j)$ and $so_v(3; j)$ in symplectic basis

The generating matrix for the simplest quantum orthogonal group $SO_v(3; j)$, $j = (j_1, j_2)$ is in the form

$$T(j) = \begin{pmatrix}
t_{11} + i j_1 j_2 \tilde{t}_{11} & j_1 t_{12} - i j_2 \tilde{t}_{12} & t_{13} - i j_1 j_2 \tilde{t}_{13} \\
j_1 t_{21} + i j_2 t_{21} & t_{22} & j_1 t_{23} - i j_2 t_{21} \\
t_{13} + i j_1 j_2 \tilde{t}_{13} & j_1 t_{12} + i j_2 \tilde{t}_{12} & t_{11} - i j_1 j_2 \tilde{t}_{11}
\end{pmatrix}. \quad (39)$$

The $R$-matrix is obtained from the standard one by Eq. (52) and is as follows

$$R_v(j) \equiv R_q(z \to Ju) =$$
Over the dual algebras $D_{2}(j_{1}, j_{2})$, $j_{1} = t_{1}, j_{2} = 1$, or $j_{1} = 1, j_{2} = t_{2}$, or $j_{1} = t_{1}, j_{2} = t_{2}$ this R-matrix may be written in the form

$$R_{e}(j) = I + Jv \tilde{R},$$

(41)

where

$$\tilde{R} = \begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & -2 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & -2 & 0 & -1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1
\end{pmatrix}.$$  

(42)

The commutation relations and additional relations of $(v, j)$-orthogonality may be obtained from Eqs.(23),(24) by straightforward calculations, so we shall concentrate our attention on the construction of quantum algebra $so_{n}(3; j)$.

The matrix functionals $L^{\pm}(j)$ have the form

$$L^{(+)}(j) = \begin{pmatrix}
l_{11} & j_{12}^{-1}l_{12} - ij_{2}^{-1}l_{12} & l_{13} - i j_{1}^{-1}j_{2}^{-1}l_{13} \\
0 & 1 & j_{1}^{-1}l_{21} - i j_{2}^{-1}l_{21} \\
0 & 0 & l_{11}^{-1}
\end{pmatrix},$$

(43)

$$L^{(-)}(j) = \begin{pmatrix}
l_{12}^{-1}l_{12} & 0 & 0 \\
0 & 1 & j_{1}^{-1}l_{21} + ij_{2}^{-1}l_{21} \\
l_{13} + i j_{1}^{-1}j_{2}^{-1}l_{13} & j_{1}^{-1}l_{12} + ij_{2}^{-1}l_{12} & l_{11}
\end{pmatrix}.$$  

(44)

Their actions on the generators (39) of quantum group $SO_{n}(3; j)$ are given by Eq.(41) and are as follows:

$$l_{11}(t_{22}) = 1, \quad l_{13}(t_{11}) = \cosh Jv, \quad ȷ_{11}(t_{11}) = -J^{-1} \sinh Jv,$$

$$l_{12}(t_{21}) = -i j_{1}^{2} J^{-1} \sinh Jv, \quad l_{12}(t_{12}) = i j_{2}^{2} (2J)^{-1} (\sinh 3Jv/2 + \sinh Jv/2),$$

$$l_{12}(t_{12}) = (\cosh 3Jv/2 - \cosh Jv/2)/2 = \tilde{l}_{12}(t_{12}), \quad \tilde{l}_{12}(t_{21}) = i j_{2}^{2} J^{-1} \sinh Jv,$$

$$l_{21}(t_{21}) = -i j_{2}^{2} (2J)^{-1} (\sinh 3Jv/2 + \sinh Jv/2), \quad l_{21}(t_{12}) = -i j_{1}^{2} J^{-1} \sinh Jv,$$

$$l_{21}(t_{21}) = i j_{1}^{2} (2J)^{-1} (\sinh 3Jv/2 + \sinh Jv/2), \quad l_{21}(t_{12}) = i j_{2}^{2} J^{-1} \sinh Jv,$$

$$l_{21}(t_{21}) = -i j_{2}^{2} (2J)^{-1} (\sinh 3Jv/2 + \sinh Jv/2), \quad l_{13}(t_{13}) = (\cosh 2Jv - 1)/2 = \tilde{l}_{13}(t_{13}),$$

$$l_{21}(t_{21}) = (\cosh 3Jv/2 - \cosh Jv/2)/2 = \tilde{l}_{21}(t_{21}).$$
$l_{13}(\tilde{t}_{13}) = -iJ^{-1}(2\sinh Jv - \sinh 2Jv), \quad \tilde{l}_{13}(\tilde{t}_{13}) = iJ(2\sinh Jv - \sinh 2Jv),$  
(45)

where $J = j_1j_2$. Only nonzero expressions are written out above. According to the additional relations (44) there are three independent generators of $so_v(3; j)$, for example, $l_{11}, l_{12}, \tilde{l}_{12}$. Their commutation relations follow from Eq. (43)

\[
\begin{align*}
    &l_{11}l_{12} \cosh Jz - l_{12}l_{11} = l_{11}l_{12}e^{2J^{-1}_1J^{-1}_2}, \\
    &l_{11}\tilde{l}_{12} \cosh Jz - \tilde{l}_{12}l_{11} = -l_{11}l_{12}e^{2J^{-1}_1J^{-1}_2}, \\
    &\left[ l_{12}, \tilde{l}_{12} \right] = -(l_{12}^2 - 1)J\sinh Jz.
\end{align*}
\]

The quantum analogue of the universal enveloping algebra of CK algebra $so_v(3; j) = \{X_{01}, X_{02}, X_{12}\}$ with the rotation generator $X_{02}$ as the primitive element of the Hopf algebra has been given in [8]. The Hopf algebra structure of $so_v(3; j; X_{02})$ is given by

\[
\Delta X_{02} = I \otimes X_{02} + X_{02} \otimes I,
\]

\[
\begin{align*}
    &\Delta X = e^{-vX_{02}/2} \otimes X + X \otimes e^{vX_{02}/2}, \quad X = X_{01}, X_{12}, \\
    &\epsilon(X_{01}) = \epsilon(X_{02}) = \epsilon(X_{12}) = 0, \quad S(X_{02}) = -X_{02}, \\
    &S(X_{01}) = -X_{01}\cos Jv/2 + j_2^2 X_{12}\sin Jv/2, \\
    &S(X_{12}) = -X_{12}\cos Jv/2 - j_2^2 X_{01}\sin Jv/2, \\
    &[X_{01}, X_{02}] = j_1^2 X_{12}, \quad [X_{02}, X_{12}] = j_2^2 X_{01}, \quad [X_{12}, X_{01}] = \frac{\sinh vX_{02}}{v}.
\end{align*}
\]

(47)

The isomorphism of $so_v(3; j; X_{02})$ and quantum algebra $so_v(3; j)$ is easily established with the help of the following relations between generators

\[
\begin{align*}
    &l_{11} = e^{vX_{02}}, \quad j_1^{-1}l_{12} = j_2 E X_{01} e^{vX_{02}/2}, \quad j_2^{-1}l_{12} = -j_1 E X_{12} e^{vX_{12}/2}, \\
    &E = i(vJ^{-1} \sin Jv)^{1/2} e^{-Jv}.
\end{align*}
\]

(48)

So the quantum orthogonal CK algebras may be constructed both as the dual to the quantum group and by the contractions of quantum orthogonal algebras.

\section{Conclusion}

Contractions are the method of receiving a new Lie groups (algebras) from the unital ones, in particular, the nonsemisimple groups (algebras) from the simple ones. In the traditional approach [4], this is achieved by introduction of a real zero tending parameter $\epsilon \to 0$. In our approach [7], contractions are described by the dual valued parameters $j_k$. In the case of FRT theory of quantum groups these contractions supplemented with the appropriate transformations of the deformation parameter lead to realization of nonsemisimple quantum groups as Hopf algebras of noncommutative functions with dual variables. So at least in CK scheme from mathematical point of view the contraction procedure is nothing else as the replacement of complex number field $C$ by the algebra $D(\epsilon)$ for both classical and quantum groups.
