September 13, 2022

Abstract

We propose a deterministic-statistical method for an inverse source problem using multiple frequency limited aperture far field data. The direct sampling method is used to obtain a disc such that it contains the compact support of the source. The Dirichlet eigenfunctions of the disc are used to expand the source function. Then the inverse problem is recast as a statistical inference problem for the expansion coefficients and the Bayesian inversion is employed to reconstruct the coefficients. The stability of the statistical inverse problem with respect to the measured data is justified in the sense of Hellinger distance. A preconditioned Crank-Nicolson (pCN) Metropolis-Hastings (MH) algorithm is implemented to explore the posterior density function of the unknowns. Numerical examples show that the proposed method is effective for both smooth and non-smooth sources given limited-aperture data.

Key words: inverse source problem, direct sampling method, Bayesian inversion, eigenfunction expansion, limited-aperture data.

1 Introduction

In recent years, the inverse problem of determining an unknown source function has attracted significant attention due to its practical importance in many applications such as the biomedical imaging and the identification of pollution sources [19, 11, 12, 9, 15, 14]. The construction of the acoustic source using single frequency data is challenging. Inverse source problems at a fixed frequency do not process a unique solution due to the existence of non-radiating sources [2, 1]. For multiple-frequency data, the uniqueness of the inverse source problem is derived in [14] for a chosen

unbounded set of the Dirichlet eigenvalues of the Laplacian using near field data (see also [21] for the uniqueness with the measurements taken on a bounded band of frequency). The use of multiple frequency data improves the stability of the inverse source problem [7]. Accordingly, many researchers consider the reconstruction of an extended acoustic source problem using multiple frequency data. Various methods have been proposed in the last decade including the continuation methods [8, 5], eigenfunction expansion methods [14, 13], and sampling type methods [9, 3, 16, 4].

Bayesian statistics is a classical approach for inverse problems [18]. Due to the increase of the computational power, Bayesian inversion has been becoming more popular [27, 28, 6, 32, 33]. Recently, focusing on partial data, we combined the deterministic methods and Bayesian inversion to successfully treat several inverse problems including an inverse scattering problem, an inverse source problem, and the reconstruction of moving point sources using limited-aperture data [23, 22, 24]. In particular, we use certain deterministic method to obtain qualitative information of the unknowns. Such information is built into the priors for the Bayesian inversion, which is then used to compute more details of the unknowns. Both the deterministic method and the Bayesian inversion use the same measured data. Numerical results show that such a combination can provide better reconstructions.

In this paper, we propose a deterministic-statistical approach for an inverse source problem using multiple frequency limited aperture data. The direct sampling method is used to find the support of the source. A disc is identified such that the support of the source is contained in the disc. Using the Dirichlet eigenfunctions of the disc (Bessel’s functions) as the basis, we expand the source function. These coefficients are the unknowns for the Bayesian inverse problem, whose posterior density function is explored using an M-H (Metropolis-Hastings) MCMC (Markov chain Monte Carlo) algorithm. The conditional mean (CM) is used to represent the solution. Numerical examples show that the proposed approach is effective for limited-aperture data.

The rest of the paper is organized as follows. In Section 2, we introduce the inverse acoustic source problem of interest. Section 3 presents the direct sampling method to reconstruct a disc that contains the support of the source. In Section 4, we first expand the unknown source using the Dirichlet eigenfunctions of the disc and propose a Bayesian approach to reconstruct the expansion coefficients. The proposed method is validated by various numerical examples in Section 5. Finally, we discuss the method and make some conclusions in Section 6.

2 The inverse source problem

Let $\Omega$ be a bounded domain in $\mathbb{R}^2$ with a Lipschitz boundary $\partial \Omega$. We assume that $\mathbb{R}^2 \setminus \overline{\Omega}$ is connected. Let $u$ be the outgoing solution to the inhomogeneous Helmholtz equation in $\mathbb{R}^2$:

$$\Delta u(x, k) + k^2 u(x, k) = f(x), \ x = (x_1, x_2) \in \mathbb{R}^2,$$

$$\lim_{r \to \infty} \sqrt{r} \left( \frac{\partial u}{\partial r} - iku \right) = 0, \quad r = |x|, \tag{2.1}$$

where $k \in K, K = [k_a, k_b], 0 < k_a < k_b$, is the wavenumber and $f(x) \in L^2(\Omega)$ with $\text{supp} f \subset \Omega$. Note that $k$ is proportional to the frequency.
There exists a unique solution $u$ to (2.1) given by (see [17])

$$u(x, k) = \int_{\Omega} \Phi_k(x, y) f(y) dy,$$

(2.2)

where $\Phi_k(x, y) = -\frac{i}{4} H_0^{(1)}(k|x - y|)$ is the fundamental solution to the Helmholtz equation and $H_0^{(1)}$ denotes the zeroth-order Hankel function of the first kind. Furthermore, $u(x, k)$ has the asymptotic behavior [17]

$$u(x, k) = e^{i \pi/4} \sqrt{\frac{1}{8k\pi}} e^{ikr} u_\infty(\hat{x}, k) + O\left(\frac{1}{r}\right)$$

as $r \to \infty$.

The far field pattern $u_\infty(\hat{x}, k)$ of $u(x, k)$ is given by

$$u_\infty(\hat{x}, k) = \int_{\Omega} \Phi_\infty(\hat{x}, y) f(y) dy,$$

(2.3)

where $\Phi_\infty(\hat{x}, y) = \exp(-ik\hat{x} \cdot y)$

(2.4)

is the far field pattern of the fundamental solution $\Phi_k(x, y)$.

We are interested in the inverse source problem of determining the unknown source $f(x)$ from the partial measurement of the far field pattern $u_\infty(\hat{x}, k)$ prescribed on the unit circle $S$ for multiple $k$’s, i.e. reconstruct $f(x)$ from $U := \{u_\infty(\hat{x}, k)|\hat{x} \in \Gamma, k \in K\}$, where $\Gamma \subset S$. In practice, the measurement data are usually discrete $u_\infty(\hat{x}_i, k_j)$ for $\hat{x}_i \in \Gamma, i = 1, 2, \ldots, I$ and $k_j \in K, j = 1, 2, \ldots, J$.

We propose a deterministic-statistical approach to reconstruct the source function in two steps. Firstly, the direct sampling method (DSM) is applied to obtain a disc $\hat{B}$ which contains the compact support of the source function $f(x)$. Secondly, we expand $f(x)$ in terms of the Dirichlet eigenfunctions of $\hat{B}$ and employ the Bayesian statistics to recover the expansion coefficients. Note that, ideally, the disc $\hat{B}$ should be such that supp$f \subset \hat{B}$ and $\hat{B} \setminus$ supp$f$ is not too large.

3 Direct Sampling Method

The direct sampling method was proposed in [20] to reconstruct small scattering objects. It is simple and effective to reconstruct the support of the unknown target (obstacle, inhomogeneous medium, source) and can process limited aperture data. Following [23, 16], for multiple frequency far field pattern, we employ the direct sampling method to determine a disc such that it contains the compact support of the source function $f(x)$. In practice, we are interested in the inverse source problem of determining the unknown source $f(x)$ from the partial measurement of the far field pattern $u_\infty(\hat{x}, k)$ prescribed on the unit circle $S$ for multiple $k$’s, i.e. reconstruct $f(x)$ from $U := \{u_\infty(\hat{x}, k)|\hat{x} \in \Gamma, k \in K\}$, where $\Gamma \subset S$. In practice, the measurement data are usually discrete $u_\infty(\hat{x}_i, k_j)$ for $\hat{x}_i \in \Gamma, i = 1, 2, \ldots, I$ and $k_j \in K, j = 1, 2, \ldots, J$.

Assume that a domain $D$ is known such that $\Omega \subset D$, i.e., the source function $f(x)$ lies inside $D$. Usually, $D$ is the region of interest and is quite large. Let $D$ be covered by a set of uniformly distributed sampling points $S$. For each point $x_p \in S$, we define an indicator function

$$I(x_p) = \frac{|\sum_{k_j} \langle u_\infty(\hat{x}, k_j), \Phi_\infty(\hat{x}, x_p) \rangle_{L^2(\Gamma)}|}{\sum_{k_j} \|u_\infty(\hat{x}, k_j)\|_{L^2(\Gamma)} \|\Phi_\infty(\hat{x}, x_p)\|_{L^2(\Gamma)}},$$

(3.1)
where the inner product $\langle \cdot, \cdot \rangle_{L^2(\Gamma)}$ is defined as

$$\langle u_{\infty}^\infty(\hat{x}, k_j), \Phi_{k_j}^\infty(\hat{x}, x_p) \rangle_{L^2(\Gamma)} = \int_{L^2(\Gamma)} u_{\infty}^\infty(\hat{x}, k_j) \Phi_{k_j}^\infty(\hat{x}, x_p) ds(\hat{x})$$

and $\Phi_{k_j}^\infty(\hat{x}, x_p)$ is the conjugate of $\Phi_{k_j}^\infty(\hat{x}, x_p)$. In the case of discrete data $u_{\infty}^\infty(\hat{x}_i, k_j), i = 1, \ldots, I, j = 1, \ldots, J$, the indicator function becomes

$$I(x_p) = \frac{\sum_{j=1}^J \sum_{i=1}^I u_{\infty}^\infty(\hat{x}_i, k_j) \cdot \Phi_{k_j}^\infty(\hat{x}_i, x_p)}{\sum_{j=1}^J \sqrt{\sum_{i=1}^I |u_{\infty}^\infty(\hat{x}_i, k_j)|^2} \sqrt{\sum_{j=1}^J |\Phi_{k_j}^\infty(\hat{x}_i, x_p)|^2}}. \quad (3.2)$$

The DSM uses the indicator function to obtain the support of $f(x)$ approximately. It is clear that $I(x_p) \in [0, 1]$. If $I(x_p)$ is small (close to 0), then the point $x_p$ is likely to lie outside the source. On the other hand, if $I(x_p)$ is large (close to 1), $x_p$ is likely to lie inside the source. We refer to [4] for some theoretical justification of the indicator function.

Based on the value of the indicator function, we are able to find a subdomain $\hat{B} \subset D$ containing the support of the source such that $I(x_p)$ is larger than a cutoff value $\gamma$ for $x_p \in \hat{B}$. In particular, we will take $\hat{B}$ as a disc with radius $R$. The radius $R$ is given by

$$R = \left( \max_{x_p \in \hat{B}, I(x_p) \geq \gamma} x_p^1 - \min_{x_p \in \hat{B}, I(x_p) \geq \gamma} x_p^1 \right) / 2, \quad (3.3)$$

where $x_p^1$ is the first component of $x_p$. The motivation to use a disc $\hat{B}$ is two folds. Firstly, a disc can easily cover the compact support of the source. Secondly, the Dirichlet eigenfunctions for a disc are known. Note that a square/rectangle domain also works.

The algorithm for multiple frequency limited aperture inverse source problems (MFLAISP) is as follows.

**DSM for MFLAISP**

1. Collect the data $u_{\infty}^\infty(\hat{x}_i, k_j), i = 1, \ldots, I, j = 1, \ldots, J$ for $x_i \in \Gamma$ and $k_j \in K$.
2. Generate sampling points set $S$ for $D$.
3. For each $x_p \in S$, compute $I(x_p)$ using (3.2).
4. Identify a disc $\hat{B}$ using $I(x_p)$ with radius $R$ given by (3.3).

We remark that other deterministic methods such as the orthogonality sampling method and extended sampling method [30, 31] can also be used as long as such a method can provide a good prediction of a disc (or a square) that contains the compact support of the source.

## 4 Bayesian Inversion

We expand the source using the Dirichlet eigenfunctions of $\hat{B}$ obtained by the DSM, and use Bayesian inversion to explore the posterior density function of the expansion coefficients. In particular, we shall construct an approximation $f_{BE}$ for the source $f$ in a finite-dimensional subspace spanned by the Dirichlet eigenfunctions of $\hat{B}$. 
Let $\| \cdot \|$ be the usual $L^2$-norm. The Dirichlet eigenvalue problem (see, e.g., [25]) is to find $\lambda$ and nontrivial $w$ such that

$$
-\Delta w = \lambda w \quad \text{in } \hat{B},
$$

$$
w = 0 \quad \text{on } \partial \hat{B}.
$$

(4.1)

We call $\lambda$ the Dirichlet eigenvalue and $w$ the eigenfunction corresponding to $\lambda$. All the eigenvalues are positive and have no finite point of accumulation. Since the Dirichlet eigenfunctions are associated to an elliptic self-adjoint compact operator on $L^2(\hat{B})$, $\{w_n\}_{n=1}^\infty$ forms a complete orthonormal set [14]. Consequently, one can expand $f$ as

$$
f(x) = \sum_{n=1}^\infty A_n w_n,
$$

(4.2)

where the Fourier coefficients are given by

$$
A_n = \int_{\hat{B}} f(x)w_n(x) \, dx.
$$

Using polar coordinate $x = (r \cos(\theta), r \sin(\theta))$, the Dirichlet eigenfunctions of a disc $\hat{B}$ centered at the origin with radius $R$ are given by [14]

$$
Q_{mn}^1(x) = \frac{1}{\sqrt{\pi R}J_{n+1}(q_{mn})} J_n \left( \frac{q_{mn}r}{R} \right) \cos(n\theta), \quad m = 1, 2, 3, \ldots, n = 0, 1, 2, \ldots,
$$

$$
Q_{mn}^2(x) = \frac{1}{\sqrt{\pi R}J_{n+1}(q_{mn})} J_n \left( \frac{q_{mn}r}{R} \right) \sin(n\theta), \quad m = 1, 2, 3, \ldots, n = 1, 2, \ldots,
$$

where $J_n$ is the Bessel function of order $n$ and $q_{mn}$ is the $m$th zero of $J_n$. These eigenfunctions satisfy

$$
\Delta Q_{mn}^j + k_{mn}^2 Q_{mn}^j = 0, \quad j = 1, 2,
$$

with wavenumber $k_{mn} = q_{mn}/R$.

An approximation $f_{BE}$ of $f$ on the disc $\hat{B}$ is given by

$$
f_{BE}(x) = \sum_{m=1}^M \left( \sum_{n=0}^N A_{mn}^1 Q_{mn}^1(x) + \sum_{n=1}^N A_{mn}^2 Q_{mn}^2(x) \right),
$$

(4.3)

where

$$
A_{mn}^1 = \int_{\hat{B}} f(x)Q_{mn}^1(x) \, dx, \quad A_{mn}^2 = \int_{\hat{B}} f(x)Q_{mn}^2(x) \, dx.
$$

Denote $H^s(\hat{B})$ the Sobolev space of order $s > 0$ equipped with the standard norm $\| \cdot \|_s$. Moreover, $H^s_0(\hat{B})$ is defined as the closure of $C_0^\infty(\hat{B})$ with respect to the norm in $H^s(\hat{B})$. The property of the Dirichlet eigenfunction expansion is stated in the following lemma [14].

**Lemma 4.1.** Let $f \in H^s_0(\hat{B})$ with $s > 1$. Furthermore, let $\{w_n\}_{n=1}^\infty$ be the set of normalized Dirichlet eigenfunctions of $\hat{B}$. There exists a constant $C$ depending only on $\hat{B}$ such that

$$
\| f - f_{BE} \| \leq C \| f \|_s N^{(1-s)/2}.
$$

(4.4)
Remark 4.1. Here we choose a disc $\hat{B}$ since the Dirichlet eigenfunctions are known analytically. One can also use rectangular domains containing the support of the source. If a general domain, e.g., a polygon, is used, the Dirichlet eigenfunctions can be computed using numerical methods such as the finite element methods (see, e.g., [25]).

Let $A$ be the vector \( \{ A_{n0}^1, A_{mn}^1, A_{mn}^2 \}_{n=1, m=1}^{N, M} \) and $X$ be the vector space $\mathbb{R}^{(2N+1)M}$. The inverse problem of the reconstruction of the source function becomes the determination of the coefficients $A \in X$ given the measurement $U$.

Based on the eigenfunction expansion (4.3), we employ the Bayesian inversion to reconstruct $A$ for the source $f(x)$ from the measurement data [27, 28]. The statistical model of the inverse source problem can be written as

$$ U = \mathcal{F}(A) + \eta, \quad (4.5) $$

where $\mathcal{F}(A) = \int_{\hat{B}} \Phi_k^\infty(\hat{x}, y) f_{BE}(y) dy$ and $\eta \sim \mathcal{N}(0, \sigma^2 \mathbb{I})$ is the Gaussian noise.

Using Bayes’ formula [27, 28], the posterior density of the random variable $A$ satisfies

$$ \pi(A|U) \propto \pi(U|A) \pi(A), \quad (4.6) $$

where $\propto$ means “proportional to”, $\pi(A)$ represents the prior density of the unknown $A$, the conditional distribution $\pi(U|A) = \mathcal{N}(U - \mathcal{F}(A), \sigma^2 \mathbb{I})$ is the likelihood function, and the posterior distribution $\pi(A|U)$ is solution to the Bayesian inverse problem. To represent the statistical information of the unknown $A$, point estimators are often used, e.g., the conditional mean (CM)

$$ A_{CM} = \mathbb{E}(\pi(A|U)). $$

We now analyze the stability of the Bayesian inverse problem. Define

$$ G(A; U) = \frac{1}{2\sigma^2} \| U - \mathcal{F}(A) \|_{L^2(\Gamma)}^2. $$

The relationship (4.6) in terms of measures $\mu^U$ and $\mu_0$ corresponding to posterior and prior densities can be written as

$$ \frac{d\mu^U}{d\mu_0}(A) = \frac{1}{L(U)} \exp \left(-G(A; U)\right), \quad (4.7) $$

where $L(U) = \int_X \exp \left(-G(A; U)\right) d\mu_0(A)$ is the normalization constant.

**Lemma 4.2.** For integer values of $n$, the Bessel function of the first kind $J_n(y)$ can be defined by the Hansen-Bessel Formula [29]

$$ J_n(y) = \frac{1}{\pi} \int_0^\pi \cos(y \sin t - nt) dt. \quad (4.8) $$

We prove a property of the operator $\mathcal{F}$ following [28].

**Lemma 4.3.** There exists a constant $C$ such that, for all $A \in X$,

$$ \| \mathcal{F}(A) \|_{L^2(\Gamma)} \leq C \| A \|_1. $$
Proof. From the Fourier-Bessel expansion (4.3) and the definition of $F(A)$, we have

$$|F(A)| = \left| \int_{\hat{B}} \Phi^\infty(\hat{x}, y) \sum_{n,m} A_{nm} Q_{nm}(y) \, dy \right| \leq \sum_{n,m} |A_{nm}| \left| \int_{\hat{B}} \exp(-ik\hat{x} \cdot y) Q_{nm}(y) \, dy \right|.$$  

(4.9)

For simplicity, we consider $\hat{B} = B(0, R)$, the disc centered at the origin with radius $R$ for the proof. The case for a general $\hat{B}$ is similar. It is clear that

$$|F(A)| \leq \sum_{n,m} \pi R^2 |A_{nm}| |Q_{nm}(y)|.$$  

(4.10)

According to (4.8), for $y \in B(0, R)$, we have that

$$|J_n(y)| = \frac{1}{\pi} \int_0^\pi \cos(y \sin t - nt) \, dt \leq 1,$$  

(4.11)

which implies that

$$|Q_{nm}(y)| \leq \frac{1}{\sqrt{\pi R} J_{n+1}(q_{mn})}.$$  

(4.12)

Combining (4.10) and (4.12), we obtain

$$|F(A)| \leq \frac{\sqrt{\pi R}}{J_{n+1}(q_{mn})} \sum_{n,m} |A_{nm}|.$$  

(4.13)

Consequently, we have that

$$\|F(A)\|_{L^2(\Gamma)} \leq \frac{\sqrt{2\pi R}}{J_{n+1}(q_{mn})} \sum_{n,m} |A_{nm}| = C \|A\|_1,$$  

(4.14)

where $C = \frac{\sqrt{2\pi R}}{J_{n+1}(q_{mn})}$.

Corollary 4.1. For all $A_1, A_2 \in X$, there exists a constant $C$, such that

$$\|F(A_1) - F(A_2)\|_{L^2(\Gamma)} \leq C \|A_1 - A_2\|_1.$$  

Definition 4.1. The Hellinger distance between two probability measures $\mu_1$ and $\mu_2$ with common reference measure $\nu$ is defined as

$$d_{\text{Hell}}(\mu_1, \mu_2) = \left( \int \left( \sqrt{\frac{d\mu_1}{d\nu}} - \sqrt{\frac{d\mu_2}{d\nu}} \right)^2 \, d\nu \right)^{1/2}.$$  

The following theorem states the well-posedness of the Bayesian inverse problem under investigation.

Theorem 4.2. Let $\mu_0$ be a Gaussian measure such that $\mu_0(X) = 1$ and $\mu^U \ll \mu_0$. For $U_1$ and $U_2$ with $\max\{\|U_1\|_{L^2(\Gamma)}, \|U_2\|_{L^2(\Gamma)}\} \leq r$, there exists $M = M(r) > 0$ such that

$$d_{\text{Hell}}(\mu_{U_1}, \mu_{U_2}) \leq M \|U_1 - U_2\|_{L^2(\Gamma)}.$$  

7
Proof. From

\[ L(U) = \int_X \exp \left( -\frac{1}{2\sigma^2} \| U - \mathcal{F}(A) \|_{L^2(\Gamma)}^2 \right) \, d\mu_0(A), \]

we have that

\[ 0 \leq L(U) \leq 1. \quad (4.15) \]

Using Lemma 4.3, we obtain that

\[
L(U) \geq \int_X \exp \left( -\frac{1}{2\sigma^2} \| U \|_{L^2(\Gamma)}^2 - \frac{1}{2\sigma^2} \| \mathcal{F}(A) \|_{L^2(\Gamma)}^2 \right) \, d\mu_0(A) \\
\geq \int_{\| A \|_1 \leq 1} \exp \left( -\frac{1}{2\sigma^2} \| U \|_{L^2(\Gamma)}^2 - \frac{C}{2\sigma^2} \| A \|_1 \right) d\mu_0(A) \\
= \exp(-M)\mu_0\{\| A \|_1 \leq 1\} > 0
\]

since \( \mu_0 \) is a Gaussian measure.

Using the mean value theorem and Lemma 4.3, for \( \mu_0 \), it holds that

\[
\begin{align*}
|L(U_1) - L(U_2)| & \\
& \leq \int_X |\exp(-G(A;U_1)) - \exp(-G(A;U_2))| \, d\mu_0(A) \\
& \leq \int_X |-G(A;U_1) - (-G(A;U_2))| \, d\mu_0(A) \\
& = \int_X \left| -\frac{1}{2\sigma^2} \| U_1 - \mathcal{F}(A) \|_{L^2(\Gamma)}^2 \right. + \left. \frac{1}{2\sigma^2} \| U_2 - \mathcal{F}(A) \|_{L^2(\Gamma)}^2 \right| \, d\mu_0(A) \\
& \leq \int_X \frac{1}{2\sigma^2} \left( \| U_1 \|_{L^2(\Gamma)}^2 + \| U_2 \|_{L^2(\Gamma)}^2 + 2\| \mathcal{F}(A) \|_{L^2(\Gamma)} \| U_1 - U_2 \|_{L^2(\Gamma)} \right) \, d\mu_0(A) \\
& \leq \int_X \frac{1}{2\sigma^2} (\| U_1 \|_{L^2(\Gamma)}^2 + \| U_2 \|_{L^2(\Gamma)} + 2\| A \|_1) \, d\mu_0(A) \| U_1 - U_2 \|_{L^2(\Gamma)}\] \\
& \leq M \| U_1 - U_2 \|_{L^2(\Gamma)}.
\end{align*}
\]

From the definition of the Hellinger distance, we have that

\[
D_{\text{Hell}}^2(\mu_{U_1}, \mu_{U_2})
= \frac{1}{2} \int_X \left\{ \frac{\exp(-G(A;U_1))}{L(U_1)} \right\}^{1/2} \left( \frac{\exp(-G(A;U_2))}{L(U_2)} \right)^{1/2} \, d\mu_0(A)
\]

\[
= \frac{1}{2} \int_X \left\{ \frac{\exp(-G(A;U_1))}{L(U_1)} \right\}^{1/2} \left( \frac{\exp(-G(A;U_2))}{L(U_2)} \right)^{1/2}
+ \left( \frac{\exp(-G(A;U_2))}{L(U_2)} \right)^{1/2} \left( \frac{\exp(-G(A;U_1))}{L(U_1)} \right)^{1/2}
\]

\[
\leq L(U_1)^{-1} \int_X \left\{ \exp \left( -\frac{1}{2} G(A;U_1) \right) - \exp \left( -\frac{1}{2} G(A;U_2) \right) \right\}^2 \, d\mu_0(A)
+ \left| L(U_1)^{-1/2} - L(U_2)^{-1/2} \right|^2 \int_X \exp(-G(A;U_2)) \, d\mu_0(A).
\]

\[ \quad (4.18) \]
With the mean value theorem and Lemma 4.3, it holds that
\[
\int_X \left\{ \exp \left( - \frac{1}{2} G(A; U_1) \right) - \exp \left( - \frac{1}{2} G(A; U_2) \right) \right\}^2 d\mu_0(A) \\
\leq \int_X \frac{1}{2} G(A; U_1) - \frac{1}{2} G(A; U_2) |^2 d\mu_0(A) \\
\leq \frac{1}{16 \sigma^4} \int_X ||U_1 - \bar{F}(A)||_{L^2(\Gamma)}^2 - ||U_2 - \bar{F}(A)||_{L^2(\Gamma)}^2 |^2 d\mu_0(A) \\
\leq M ||U_1 - U_2||_{L^2(\Gamma)}^2 .
\]  
(4.19)

Using the bounds on $L(U_1)$ and $L(U_2)$, we have that
\[
|L(U_1)^{-3/2} - L(U_2)^{-3/2}|^2 \leq M \max \left( L(U_1)^{-3}, L(U_2)^{-3} \right) |L(U_1) - L(U_2)|^2 \\
\leq M ||U_1 - U_2||_{L^2(\Gamma)}^2 .
\]  
(4.20)

Combining (4.15)-(4.20), we conclude that
\[
d_{\text{Hell}}(\mu_{U_1}, \mu_{U_2}) \leq M ||U_1 - U_2||_{L^2(\Gamma)}. 
\]

To explore the posterior probability distribution of the unknown $A$, we employ the preconditioned Crank-Nicolson (pCN) Metropolis-Hastings (MH) algorithm for the Markov chain Monte Carlo (MCMC) method [10].

**pCN-MH:**
1. Set $j \leftarrow 0$ and choose an initial value $A^{(0)}$.
2. Propose a move according to
   \[
   \tilde{A}^{(j)} = \left( 1 - \beta^2 \right)^{1/2} A^{(j)} + \beta W_n, \quad W_n \sim \mathcal{N}(0, I).
   \]
3. Compute
   \[
   \alpha(A^{(j)}, \tilde{A}^{(j)}) = \min \left\{ 1, \exp \left( -G(\tilde{A}^{(j)}; U) + G(A^{(j)}; U) \right) \right\}.
   \]
4. Draw $\tilde{\alpha} \sim U(0, 1)$. If $\alpha(A^{(j)}, \tilde{A}^{(j)}) \geq \tilde{\alpha}$, set $A^{(j+1)} = \tilde{A}^{(j)}$. Else, $A^{(j+1)} = A^{(j)}$.
5. When $j = \text{MaxIt}$, the maximum sample size, stop. Otherwise, set $j \leftarrow j + 1$ and go to Step 2.

**5 Numerical Examples**

In this section, we present some numerical experiments to demonstrate the effectiveness of the proposed deterministic-statistical method.

In all examples, the synthetic far field data is generated by decomposing $\Omega$ into a triangular mesh $\mathcal{T}$ and approximating (2.3) by
\[
u^\infty(\hat{x}, k) \approx \sum_{T \in \mathcal{T}} \Phi^\infty_k(\hat{x}, y_T)f(y_T)|T|, \quad \hat{x} = (\cos \theta, \sin \theta),
\]  
(5.1)
where \( T \in \mathcal{T} \) is a triangle, \( y_T \) is the center of \( T \), and \( |T| \) denotes the area of \( T \). The observation directions \( \theta \)'s are chosen from the following three apertures:

\[
\Gamma_1 = 0 : \frac{\pi}{26} : 2\pi - \frac{\pi}{26}, \quad \Gamma_2 = 0 : \frac{\pi}{26} : \pi - \frac{\pi}{26}, \quad \Gamma_3 = 0 : \frac{\pi}{26} : \frac{\pi}{2} - \frac{\pi}{26},
\]

i.e. \( \Gamma_1 \) is the full aperture, \( \Gamma_2 \) is a half of the full aperture and \( \Gamma_3 \) is a quarter of the full aperture. To ensure the accuracy of the far field data, we use fine meshes with the mesh size \( h \approx 0.01 \). The perturbed far field measurement is given by

\[
u^m(\hat{x}, k) := u^\infty(\hat{x}, k) + 0.03(\max_{\hat{x}} \Re(u^\infty(\hat{x}, k)) + i \max_{\hat{x}} \Im(u^\infty(\hat{x}, k))),
\]

where \( \Re \) and \( \Im \) represent the real and imaginary part, respectively.

For the DSM, the measurement data are the far field pattern correspond to wavenumbers \( K_1 = 1 : 1 : 3 \). The domain \( D \) is the square \([-4, 4]^2\), which is uniformly covered by 81 × 81 sampling points. The cutoff values for the indicator function of three scenarios \( \Gamma_1, \Gamma_2 \) and \( \Gamma_3 \) are \( \gamma = 0.41, 0.64 \) and 0.70, correspondingly. These \( \gamma \)'s are obtained by trial and error. In the contour plots of the indicator \( I_{p_\theta} \) over the sampling domain \( D \), the red dashed line represents the exact boundary of source \( f(x) \) and the estimation of the support is the black circle. In fact, we will see that the DSM uses a smaller set of the far field data than the Bayesian inversion does. In general, a satisfactory reconstruction of the disc \( \hat{B} \) can be obtained using the data for a few smaller \( k \)'s.

Once we obtain the approximate disc \( \hat{B} \), we choose \( N = 2, M = 5 \) in (4.3) for the approximation \( f_{BE} \) (25 terms in total). The measurement for the Bayesian method is corresponding to the wavenumbers \( K = 1 : 1 : 20 \). In the MCMC we take \( \pi(A) = \mathcal{N}(0, 0.01) \) and \( \sigma = 0.04 \) in the likelihood. To compute the posterior distribution of \( A \), we apply \( \text{pCN-MH} \) with \( \beta = 0.001 \). A Markov chain of sample size 120,000 are drawn in the Bayesian inversion, of which the first 20,000 are discarded. The CM is then used as a point estimate for \( A \). To evaluate the performance of the reconstruction, we compute both the absolute error (AE) \( \| f - f_{BE} \|_2 \) and the relative error (RE) \( \frac{\| f_{BE} - f \|_2}{\| f \|_2} \).

**Example 1:** Let

\[
f(x) = 3Q_{11}(x), \quad x \in B(0, 0.9),
\]

i.e., the source function is a constant multiple of an eigenfunction \( Q_{11} \) for \( B(0, 0.9) \). We first show the performance of the Bayesian inversion when the compact support of \( f(x) \) is known exactly, namely, \( \hat{B} = B(0, 0.9) \). Due to (5.2), we expect that the CM of the coefficient for \( Q_{11} \) is 3 and the CM's of the other coefficients are zeros in (4.3). Using the Bayesian method for three apertures, \( \Gamma_1, \Gamma_2 \) and \( \Gamma_3 \), the reconstructions \( f_{BE} \) are shown in Fig. 1. It can be seen that the samples for the coefficient of \( Q_{11}(x) \) accumulate around 3 and the rest accumulate around 0 for all three apertures.

Next we use the proposed deterministic-statistical method to reconstruct \( f(x) \) without the knowledge of its support. The DSM is first used to find a disc \( \hat{B} \) containing the support of \( f(x) \). For all three apertures \( \Gamma_1, \Gamma_2 \) and \( \Gamma_3 \), the indicator functions \( I(x_\theta)'s \) and the discs \( \hat{B} \)'s obtained are shown in the top row of Fig. 2. The associated approximate radii of \( \hat{B} \)'s are 1.3601, 1.4213 and 1.0817 (see Table 1). All \( \hat{B} \)'s are close to the exact support, which indicates the effectiveness of the DSM.
Figure 1: Example 1 (exact support known). Top row: the histograms of the coefficients for $f_{BE}$ when the support is known exactly. Bottom row: the reconstructed $f_{BE}$ and exact $f$. Left column: $\Gamma_1$. Middle column: $\Gamma_2$. Right column: $\Gamma_3$.

In the Bayesian inversion stage, based on the reconstructed $\hat{B}$, we explore the statistical information of the coefficients for $f_{BE}$ using pCN-MH. The second row of Fig. 2 shows the histograms of the coefficients, which tend to converge. Note that the eigenfunctions of $\hat{B}$ are used and the coefficients for $f_{BE}$ are not zero in general. The exact source function $f$ and the reconstructions $f_{BE}$ are shown in the third row of Fig. 2. The absolute and the relative errors of the reconstructions using the CM’s are listed in Table 2 (first four columns). It can be seen that all the approximate source functions $f_{BE}$’s are quite close to the exact sources. For all three apertures, the absolute errors are small and the relative errors are less than 7%.

**Example 2:** Let

$$f(x) = 2(0.81 - (x_1^2 + x_2^2))\chi_{x_1^2 + x_2^2 \leq 0.81},$$

where $\chi$ is the characteristic function. The exact support of $f(x)$ is $B(0,0.9)$. The contour plots of the indicator functions by the DSM are shown in the first row of Fig. 3 for $\Gamma_1$, $\Gamma_2$ and $\Gamma_3$. The radii of the discs $\hat{B}$’s are 0.9055, 1.1180 and 1.0817, which are listed in Table 1. The histograms of the coefficients are shown in the second row of Fig. 3. The reconstructed $f_{BE}$’s and the exact $f$ are shown in the third row of Fig. 3. The errors are listed in Table 2. It can be seen that as the measurement aperture become less, the errors increase.

Table 1: Exact support of $f(x)$ and the radii of the discs by the DSM.

| Exact support | Example 1 | Example 2 | Example 3 | Example 4 | Example 5 |
|---------------|-----------|-----------|-----------|-----------|-----------|
| $B(0,0.9)$    | 1.3601    | 0.9055    | 0.8246    | 1.7205    | 0.9849    |
| $\Gamma_1$   | 1.4213    | 1.1180    | 1.0198    | 1.5000    | 1.2166    |
| $\Gamma_2$   | 1.0817    | 1.0817    | 1.0630    | 1.2806    | 1.1705    |
| $\Gamma_3$   | 1.1180    | 1.0198    | 1.5000    | 1.2166    | 1.1705    |
Figure 2: Example 1 (reconstructed support). First row: contour plots of the indicators for the DSM. Second row: the histograms of the coefficients for $f_{BE}$. Third row: the reconstructed $f_{BE}$ and exact $f$. Left column: $\Gamma_1$. Middle column: $\Gamma_2$. Right column: $\Gamma_3$.

Table 2: Absolute error (AE) $\|f - f_{BE}\|_2$ and the relative error (RE) $\frac{\|f_{BE} - f\|_2}{\|f\|_2}$.

|        | Example 1 | Example 2 | Example 3 | Example 4 | Example 5 |
|--------|-----------|-----------|-----------|-----------|-----------|
| $\Gamma_1$ | 0.1274 6.02% 0.1184 5.61% | 0.0455 3.06% 0.0735 7.17% | 0.3414 25.97% | 0.2127 13.43% |
| $\Gamma_2$ | 0.0833 3.94% 0.1309 6.20% | 0.0606 4.07% 0.1691 16.62% | 0.3406 25.81% | 0.2697 17.13% |
| $\Gamma_3$ | 0.0346 1.63% 0.1224 5.79% | 0.0667 4.48% 0.2752 26.99% | 0.4083 30.88% | 0.3021 19.14% |

Example 3: Let

$$f(x) = 5 \exp(-45x_1^2 - 30x_2^2).$$

In this case, $f(x) \neq 0$ for all $x \in \mathbb{R}^2$. However, $f(x)$ is very close to 0 when $|x|$ is large and the approximation (4.3) for $f(x)$ is still valid approximately for $\hat{B}$ large enough. We consider a rough support of $f(x)$: $B^* = \{x \in \mathbb{R}^2 ||f(x)|| \leq 10^{-10}\}$. We have $B^* \approx B(0, 0.7471)$. The contour plots of the indicator functions by the DSM are shown in the first row of Fig. 4 for $\Gamma_1$, $\Gamma_2$ and $\Gamma_3$. The reconstructed domains $\hat{B}$ contains $B^*$ and are close to it for all three apertures. The radii of the reconstructed discs $\hat{B}$’s are 0.8246, 1.0198 and 1.0630, which are listed in Table 1. The histograms of the coefficients are shown in the second row of Fig. 4. The reconstructed $f_{BE}$’s and the exact $f$ are shown in the third row of Fig. 4. The errors are listed in Table 2. Again the measurement aperture become less as the errors increase.
Example 4: Let
\[ f(x) = 15x_1x_2(0.81 - (x_1^2 + (x_2/1.2)^2))\chi\{(x_1^2 + (x_2/1.2)^2)\leq 0.81\}. \]

The compact support of \( f(x) \) is an ellipse with the minor radius 0.9 and major radius 1.08. The approximate discs by the DSM (first row of Fig. 5) provide reliable estimates for the support \( f(x) \), which are given in Table 1. The histograms of the coefficients are shown in the second row of Fig. 5. The reconstructed \( f_{BE} \)’s and the exact \( f \) are shown in the third row of Fig. 5. The errors are listed in Table 2. Again the errors increase as the measurement aperture become less.

Example 5: The last example is a discontinuous source function. Let
\[ f(x) = \chi\{(x_1^2 + x_2^2)\leq 0.81\}. \]

The contour plots of the indicator functions by the DSM are shown in the first row of Fig. 6 for \( \Gamma_1, \Gamma_2 \) and \( \Gamma_3 \). The radii of the reconstructed discs \( \hat{B} \)’s are 0.9849, 1.2166 and 1.1705 listed in Table 1. The histograms of the coefficients are shown in the second row of Fig. 6. The reconstructed \( f_{BE} \)’s and the exact \( f \) are shown in the third row of Fig. 6. The errors are listed in Table 2. The main features of the discontinuous source \( f(x) \) such as the value and discontinuity are reconstructed well.
Figure 4: Example 3. First row: contour plots of the indicators for the DSM. Second row: the histograms of the coefficients for $f_{BE}$. Third row: the reconstructed $f_{BE}$ and exact $f$. Left column: $\Gamma_1$. Middle column: $\Gamma_2$. Right column: $\Gamma_3$.

6 Conclusions

In this paper, we combine the DSM and Bayesian approach to reconstruct an extended source using the multiple frequency limited aperture far field data. In the first step, the DSM is used to obtain an approximation of the compact support (a disc) of the source. Using the eigenfunctions of the disc, we expand the source and employ the Bayesian inverse to recover the expansion coefficients.

Numerical examples, including a discontinuous source function, show the effectiveness of the proposed method. It is observed that as the aperture becomes smaller the reconstruction error increases. Nonetheless, the results are satisfactory for limited aperture data.

The cutoff value for the indicator function of the DSM is chosen by trial and error. We are investigating other methods to avoid choosing ad-hoc cutoff values. Algorithms that can improve the acceptance rate of the samplings in the MCMC method are also worth efforts to improve efficiency. Another interesting topic is the case when the source function is also frequency dependent, i.e, $f$ depends on $k$ as well.
Figure 5: Example 4. First row: contour plots of the indicators for the DSM. Second row: the histograms of the coefficients for $f_{BE}$. Third row: the reconstructed $f_{BE}$ and exact $f$. Left column: $\Gamma_1$. Middle column: $\Gamma_2$. Right column: $\Gamma_3$.
