Porcine delta coronavirus (PDCoV) is a novel emerging enterocytotropic virus causing diarrhea, vomiting, dehydration, and mortality in suckling piglets. Long non-coding RNAs (lncRNAs) are known to be important regulators during virus infection. Here, we describe a comprehensive transcriptome profile of lncRNA in PDCoV-infected swine testicular (ST) cells. In total, 1,308 annotated and 1,190 novel lncRNA candidate sequences were identified. Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis revealed that these lncRNAs might be involved in numerous biological processes. Clustering analysis of differentially expressed lncRNAs showed that 454 annotated and 376 novel lncRNAs were regulated after PDCoV infection. Furthermore, we constructed a lncRNA-protein-coding gene co-expression interaction network. The KEGG analysis of the co-expressed genes showed that these differentially expressed lncRNAs were enriched in pathways related to metabolism and TNF signaling. Our study provided comprehensive information about lncRNAs that would be a useful resource for studying the pathogenesis of and designing antiviral therapy for PDCoV infection.

Keywords: PDCoV infection, RNA-seq, lncRNA, TNF, metabolic pathway

INTRODUCTION

Long non-coding RNAs (lncRNAs), which are transcripts larger than 200 nt in length that lack protein-coding ability, have previously been described in mammalian cells (Kapranov et al., 2007; Mattick and Rinn, 2015). Most of them have a structure similar to mRNA; they have a 5′ methylguanosine cap and are usually spliced and polyadenylated at their 3′ termini. Notably, lncRNA expression shows significant cell and tissue specificity (Mercer et al., 2008; Derrien et al., 2012). Emerging evidence shows that non-coding RNAs have a regulatory role in multiple cellular processes, such as genomic imprinting, chromatin modification, and alternative splicing of RNA (Mercer et al., 2009). Moreover, some diseases such as cancer and neurological disorders are also related to the dysregulated expression of lncRNA (Qureshi et al., 2010; Tsai et al., 2011). Numerous studies have been conducted to ascertain their functional role during viral infection. For example, NARV can promote influenza virus replication and virulence through negatively...
regulating the initial transcription of varieties of interferon-stimulated genes (ISGs) (Ouyang et al., 2014). IncRNA-ACOD1, named by its neighboring coding gene acod1, significantly reduces virus multiplication by directly interacting with the metabolic enzyme glutamic-oxaloacetic transaminase (Wang et al., 2017). Neat1, one of the IncRNAs induced by HIV-1 infection, is retained in the nucleus and serves as a scaffold for the nuclear paraspeckle substructure. Importantly, Neat1 deficiency enhances HIV-1 replication (Zhang et al., 2013). Although large amounts of data have proved that several IncRNAs are involved in different kinds of virus infection, the mechanisms by which they act are still largely unknown.

Porcine delta coronavirus (PDCoV), a novel emerging pathogenic enterocytotropic virus, was first discovered from the feces of pigs in Hong Kong in 2012. It is an enveloped, single-stranded positive-sense RNA virus. It belongs to the genus Deltacoronavirus in the family Coronaviridae of the order Nidovirales (Woo et al., 2012). The genome length of PDCoV is approximately 25.4 kb. It is similar in structure to other coronaviruses, with shorter non-coding regions (5′-UTR and 3′-UTR) at both terminals. The 3′/4 genome from the 5′ end contains two overlapping open reading frames, ORF1a and ORF1b, encoding the pp1a and pp1b, respectively. The downstream of the genome encodes structural protein spike (S), envelope (E), membrane (M), accessory proteins N56, structural protein nucleocapsid (N), and accessory proteins NS7 and NS7a. A total of 15 non-structural proteins are encoded by the 5′ terminal of the genome (Fang et al., 2017). PDCoV mainly causes acute, watery diarrhea, vomiting, dehydration, and mortality in suckling piglets, including lesions in the stomach and lungs (Ma et al., 2015). The first outbreak of PDCoV infection was reported in the United States in early 2014 and, to date, it has been detected in Canada, South Korea, China, Thailand, and Vietnam, thus posing a huge threat to the swine industry and attracting a great deal of attention (Lee and Lee, 2014; Dong et al., 2016; Lorsirigoot et al., 2017; Ajayi et al., 2018; Saeng-Chuto et al., 2019).

During infection, the accessory and non-structural proteins of PDCoV usually perform multiple functions to promote replication in infected cells. A previous study showed that N56 interaction with RIG-I/MDA5 attenuated the binding activity between RIG-I/MDA5 and double-stranded RNA, resulting in a reduced level of IFN-β production (Fang et al., 2018). Also, the non-structural protein nsp5, a 3C-like protease, is an important molecule in suppressing type I IFN signaling (Zhu et al., 2017b). In addition, NEMO, an essential modulator of NF-κB, can also be cleaved by nsp5, causing inhibition of IFN-β production (Zhu et al., 2017a). Though there are many reports of immune evasion by PDCoV, the precise pathogenic mechanism of PDCoV is largely unclear.

Based on the increasing number of reports on host IncRNAs associated with virus infection, we are interested in investigating whether host IncRNAs were involved in PDCoV infection. In this study, genome-wide profiling of IncRNAs in swine testicular (ST) cells infected with PDCoV was performed using RNA-seq. We identified 830 differentially expressed IncRNAs from PDCoV-infected cells. An integrative analysis of IncRNA alterations suggested their putative role in regulating the expression of several key genes in metabolic and TNF signaling pathways during infection. In conclusion, this work supports the role of IncRNAs as important regulators of PDCoV infection.

**MATERIALS AND METHODS**

**Cells and Viruses**

Swine testicular cells and porcine jejunum intestinal epithelial cells (IPEC-J2) were grown in DMEM supplemented with 10% (vol/vol) FBS (Gibco, Carlsbad, CA, United States) at 37°C in a humidified 5% CO₂ atmosphere. The PDCoV-CH-HA3-2017 (MK040455) strain, stored in our laboratory, was propagated in ST cells.

**Viral Infection and RNA Extraction**

For RNA-seq, ST cells were infected with PDCoV at a multiplicity of infection (MOI) of 10; the medium for PDCoV infection was DMEM containing 0.2 ug/ml Trypsin that had been TPCK-treated (Millipore Sigma, St. Louis, MO, United States) for 11 h. Mock-infected cells were placed in the same volume of DMEM, with the same concentration of TPCK-treated Trypsin. Total RNA was isolated from each group using SuPerfeciTR™ Total RNA Isolation Reagent (Pufeic, Shanghai, China) according to the manufacturer’s instructions. The RNA quality was checked by 1% agarose gel electrophoresis. The purity and concentration of RNA were measured by NanoPhotometer® spectrophotometer (IMPLEN, München, Germany) and Qubit® RNA Assay Kit in Qubit® 2.0 Fluorometer (Life Technologies, Camarillo, CA, United States). RNA integrity was assessed using the RNA Nano6000 Assay Kit of the Bioanalyzer 2100 system (Agilent Technologies, Santa Clara, CA, United States). For quantitative RT-PCR (RT-qPCR), ST and IPEC-J2 cells were infected or mock-infected with PDCoV at an MOI of 10 and harvested at the indicated time. All experiments were conducted in triplicate.

**RNA-Seq and Data Analysis**

Sequencing libraries were generated using the rRNA-depleted RNA with a NEBNext® Ultra™ Directional RNA Library Prep Kit (New England Biolabs, Ipswich, MA, United States). After determining the quality of the library, RNA-seq was performed using an Illumina HiSeq™ 4000 (Illumina, San Diego, CA, United States) to generate raw reads. After removing poly-N sequences, adapters, and low-quality reads, clean reads were obtained and the paired-end reads were aligned to Ensemble pig genome (Release 76). IncRNAs were identified using TopHat2 (v2.0.9), and reads that were mapped to the pig genome were assembled using Cufflinks v2.1.1 (Trapnell et al., 2010). Cuffdiff (v2.1.1) was used to calculate the FPKMs of both IncRNAs and coding genes in each sample. Gene FPKMs were computed by summing the FPKMs of transcripts in each gene group, and differentially expressed (DE) transcripts were assigned where there was a statistically significant level of expression ($p < 0.05$). RNA-seq and data analysis were completed by Novogene.
GO and KEGG Enrichment Analysis

Gene Ontology (GO) enrichment analysis of differentially expressed genes or lncRNA target genes was conducted with respect to biological process, molecular function, and cellular component with the GOseq R package, in which gene length bias was corrected. Kyoto Encyclopedia of Genes and Genomes (KEGG) was used to perform pathway enrichment analysis1. KOBASE software was used to test the level of statistical significance of enrichment of differentially expressed genes and/or lncRNA target genes in KEGG pathways (Mao et al., 2005).

RT-qPCR, RT-PCR, and Statistical Analysis

To determine the reliability of the RNA-seq data, 15 differentially expressed lncRNAs were randomly selected to test the expression by RT-qPCR. Total RNA was extracted from ST and IPEC-J2 cells using SuPerfecTRI™ Total RNA Isolation Reagent (Pufei, Shanghai, China). First-strand cDNA was synthesized with a reverse transcriptase kit (Vazyme, Nanjing, China). RT-qPCR was performed with a SYBR Green master mix (Vazyme, Nanjing, China) on the LightCycler 96 (Roche, Basel, Switzerland). The PDCoV M gene was detected by RT-PCR. All the primers are presented in Table 1. Relative expressions were calculated using the 2−ΔΔCt method with GAPDH as the internal control. Comparisons between groups were made using two-way ANOVA. The data reported are the mean ± SEM. Differences were considered statistically significant when p < 0.05.

RESULTS

RNA-Seq and IncRNA Screening in PDCoV-Infected Cells

To identify the lncRNAs in PDCoV-infected cells, we sequenced the transcriptomes of the ST cells with or without PDCoV infection using high-throughput RNA sequencing. Robust and reproducible data were obtained from all samples, and more than 1 × 10^8 clean reads per sample were retained after removing reads containing adapter or poly-N sequences and reads with low quality. Afterward, all clean reads were aligned onto the pig reference genome (Release 76) using TopHat2. The level of statistical significance of enrichment of differentially expressed lncRNAs was performed using Cytoscape (v3.5.1) (Shannon et al., 2003).

CONSTRUCTION OF THE lncRNA-PROTEIN-CODING GENE CO-EXPRESSION NETWORK

For each lncRNA, the Pearson correlation coefficient of its expression value with that of each protein-coding gene was calculated. Under the conditions of an absolute value of the Pearson correlation coefficient >0.998 and p < 0.00001, the interaction network of the differentially expressed lncRNAs and protein-coding gene co-expression pairs was then constructed using CytoScape (v3.5.1) (Shannon et al., 2003).

It has been reported that lncRNAs, in comparison with protein-coding genes, usually share some common genomic features to their sequences. They are generally shorter in length, have fewer but longer exons, and there is lower evolutionary sequence conservation, with only ~15% of mouse lncRNAs having homologs in humans. lncRNAs also demonstrate low expression levels (the median is ~10% of that of protein-coding genes) (Heward and Lindsay, 2014). To further determine the characteristics of the lncRNAs identified in the present study, we compared the transcription length, exon number, and degree of conservation between protein-coding genes and lncRNAs. Conservation analysis of exons, introns, and promoters of lncRNAs and protein-coding genes showed that the exons of protein-coding genes were the most conserved and the exons of...
IncRNAs were far less conserved (Figure 1C). Furthermore, fewer exons and shorter ORFs were found in IncRNAs, which was also consistent with the reported IncRNAs (Figures 1D,E).

**Whole Transcriptome-Wide Functional Prediction of IncRNAs in PDCoV-Infected Cells**

Long non-coding RNAs sequences are poorly conserved and do not appear to form large homologous families, so it is difficult to infer their common ancestors by sequence similarity (Ponting et al., 2009). Therefore, it is challenging to predict the functions of a type of IncRNA on the basis of its sequence or structure. There have been reports of using genome-wide association analysis between IncRNAs and the co-expressed and/or co-regulated protein-coding genes to characterize the function of the IncRNA (Huarte et al., 2010). To investigate the putative role of IncRNAs, we first analyzed the whole RNA-seq profiles to identify target protein-coding genes whose location or expression was significantly correlated with the candidate IncRNA. For co-located target gene prediction, we searched coding regions 100 k upstream and downstream of IncRNA. In total, 8,812 pairs of IncRNA-protein-coding genes, containing 2,088 IncRNAs and 3,566 protein-coding genes, were identified (Supplementary Table S3). For co-expressed target gene prediction, the expression correlation between IncRNAs and protein-coding genes was evaluated. When the required Pearson correlation coefficient was set above 0.95, 1,048,575 pairs of IncRNA-protein-coding genes, containing 1,730 IncRNAs and 10,581 protein-coding genes, were obtained (Supplementary Table S4). We next performed GO and KEGG pathway analysis for the target genes of IncRNAs. The top 20 GO and KEGG pathways with the highest representation of each term are reported (Figure 2 and Supplementary Tables S5, S6). KEGG enrichment analysis revealed that pathways related to the immune system and metabolism were preferentially targeted. The GO-term analysis was divided into three main categories: cellular component, biological process, and molecular function. Significantly, a large number of biological processes, like protein-DNA complex assembly, DNA packaging and transcription, and the cellular macromolecule metabolic process, were enriched. Furthermore, protein binding and nucleic acid binding and the nucleosome and organelles, belonging to molecular function and cellular component, respectively, were also enriched. GO and KEGG pathway enrichment analysis of target genes revealed that IncRNAs may act in cis or trans to participate in the regulation of expression of multiple important genes in different processes including protein binding, DNA transcription, metabolism, and immune response.
Clustering Analysis Identified Differentially Expressed IncRNAs in PDCoV-Infected Cells

To identify the PDCoV-associated IncRNAs, Cuffdiff software was used to investigate the differentially expressed (DE) IncRNAs in PDCoV-infected cells. The hierarchical clustering heat map in Figure 3A shows the DE IncRNA expression profiling data. Out of the 1,308 annotated and 1,190 novel IncRNAs, we obtained 454 annotated DE IncRNAs (225 up-regulated and 229 down-regulated) and 376 novel DE IncRNAs (252 up-regulated and 124 down-regulated) after PDCoV infection (p < 0.05; Supplementary Table S7). Importantly, we observed 20 IncRNAs whose expression levels were decreased to FPKM = 0 after PDCoV infection, while the FPKMs of another 12 IncRNAs, all novel IncRNAs, were 0 before PDCoV infection (Supplementary Table S7). This suggests that these 32 IncRNAs, though they have very low expression levels, might be strongly associated with the viral infection. Furthermore, to evaluate the reliability of RNA-seq data analysis, 15 IncRNAs were selected for RT-qPCR analysis in PDCoV-infected cells. As shown in Figure 3B, the expression levels of the 15 selected IncRNAs, though exhibiting no significant differences at 4 h post-infection (hpi), were all significantly changed at 11 hpi in ST cells. Also, different expression patterns of IncRNAs were detected in IPEC-J2 cells. As shown in Figure 3C, 11 out of the 15 selected RNA were significantly altered at 11 hpi, and all of them were differently expressed at 24 hpi. For both ST and IPEC-J2 cells, they had a strong expression pattern consistent with the RNA-seq results (Table 2).

Co-location Analysis of DE IncRNAs Revealed Their Potential Regulation of Their Neighboring Protein-Coding Genes

The IncRNA in the genome is not randomly distributed, so locus classification will be an effective first step in analyzing its regulatory functions at the genome level (Luo et al., 2016). In general, IncRNAs function either in cis or in trans to affect the transcription of genes within or far from the same genomic locus (Clark and Blackshaw, 2014). To understand the potential functional association between IncRNAs and cognate genes, we investigated their genomic distribution pattern relative to protein-coding loci and classified all DE IncRNAs to ascertain their potential biological roles. All DE IncRNAs were classified into six categories comprising sense-upstream IncRNA, sense-downstream IncRNA, sense-overlapping IncRNA, antisense-upstream IncRNA, antisense-downstream IncRNA and antisense-overlapping IncRNA. As shown in Figure 4A, 26% of DE IncRNAs were located in the same strand but upstream of protein-coding genes and 24% were located downstream, while antisense-upstream and antisense-overlapping comprised...
27 and 1%, respectively, and the remaining 22% were antisense-downstream lncRNAs. Next, in order to define the lncRNA functions more precisely, GO enrichment analysis of the co-located genes of up- and down-regulated lncRNAs were analyzed independently. The results showed that protein-coding genes associated with DE lncRNAs were mainly enriched in terms of molecular function and cellular component, primarily under the category of nucleic acid binding and intracellular membrane-bounded organelle (Figure 4B). Notably, by analyzing the relative expression level, we found that antisense lncRNA and protein-coding genes were specifically co-expressed, in which two pairs showed a positive and three pairs showed a negative correlation in their expression patterns (Figure 4C and Supplementary Table S8). We speculated that these antisense lncRNAs act in cis to modulate the expression of their cognate genes.

**Correlation Analysis Provided a Resource to Functionally Identify PDCoV Driver Metabolism- and Immunity-Related lncRNAs**

The functional association between regulatory lncRNA and protein-coding gene transcripts can be determined by performing expression correlation analysis coupled with ascertaining their putative role in related physiological processes. To further investigate the potential mechanism of action of the PDCoV-associated lncRNAs, the DE lncRNAs and their predicted target DE protein-coding genes were investigated by delineating lncRNA-protein-coding gene functional interactions. Here we identified 1,048,575 pairs of DE lncRNA-DE protein-coding genes, containing 821 lncRNAs and 8,799 protein-coding genes (p < 0.01). Next, KEGG pathway analysis was repeated once again (Figure 5A), and we found that metabolic and TNF signaling pathways were significantly enriched.

The interaction network involving the metabolic and TNF signaling pathways was then constructed. Several key genes in metabolism were positively or negatively regulated by lncRNAs (Figure 5B). Of the significantly enriched genes, ATP5L and ATP5F1, two of the mitochondrial membrane ATP synthase subunits, were regulated by LNC-000625, LNC-001104, ALDBSSCT0000008902, and ALDBSSCT000006348.

In addition, three lncRNAs, LNC-000459, LNC-000258, and ALDBSSCT0000005568, might regulate acyl-coenzyme A thioesterase four expression. These results suggest that these lncRNAs might be involved in the regulation of metabolic processes particularly involving energy and lipid metabolism. Meanwhile, an inducible program of inflammatory gene expression is central to antiviral defense. Many of them, i.e., CCL5, CCL20, CXCL2, CXCL10, MAP3K8, NF-κB1, and interleukin 6 (IL-6), were protein-coding genes known to have roles in the inflammatory response. In the network (Figure 5C), eight lncRNAs have putative regulatory roles in IL-6 expression. Six of them, LNC-000173, LNC-000269, LNC-000242, LNC-000657, ALDBSSCT0000009132, and ALDBSSCT0000001339, might exert positive regulation, while LNC-001173 and ALDBSSCT0000010894 showed the opposite effect. This suggests that these lncRNAs might act as the regulatory module of the circuit that is involved in the inflammatory response.

**DISCUSSION**

Numerous studies have shown that lncRNAs play a key role during viral infection. The lncRNAs THRIL, NeST, NEAT, and lincRNA-Cox2 can participate in immune responses against viral infection mainly through regulating the expression of TNF-α, IFN-γ, IL8, and inflammatory response, respectively (Carpenter et al., 2013; Gomez et al., 2013; Imamura et al., 2014; Li et al., 2014). PDCoV is an important enteric virus mainly causing diarrhea in suckling pigs. Infection with PDCoV causes changes in the expression levels of several host cell proteins of host innate immune response, but little is known about the critical roles of lncRNAs in these processes.

Here, we performed RNA-seq to identify the lncRNAs involved in PDCoV infection. The results of comparing clean reads to the genome showed that more than 60% of reads are protein-coding genes, and no lncRNA classifications were identified due to the limited lncRNA database annotation in pig. In our results, 1,190 novel lncRNAs were identified. Further analysis showed that the basic characteristics of these novel lncRNAs are consistent with the known ones. Our RNA-seq results further enrich the pig lncRNA database.

In total, we found 454 annotated and 376 novel lncRNAs that were differentially expressed during PDCoV infection. These lncRNAs were classified as sense-upstream lncRNA, sense-downstream lncRNA, sense-overlapping lncRNA, antisense-upstream lncRNA, antisense-downstream lncRNA, and antisense-overlapping lncRNA. Many antisense-overlapping lncRNAs have inverse expression patterns with their sense transcript counterparts. This suggests that these antisense-overlapping lncRNAs may have a negative regulatory effect on them. In contrast, many lncRNAs that do not contain overlapping sequences display expression patterns correlated with their neighboring protein-coding gene transcripts. In the present study, two out of five antisense overlapping lncRNAs were found to have high consistency in their expression (Figure 4). Similarly, the lncRNA Evx1as, which initiates
FIGURE 5 | Correlation analysis provides a resource to functionally identify PDCoV driver metabolism- and immunity-related lncRNAs. (A) The top 20 overrepresented KEGG pathways of co-expressed genes. (B, C) The network of co-expressed lncRNA-protein-coding gene pairs based on a threshold of a Pearson’s correlation coefficient of 0.998. The network of lncRNAs with metabolic- (B) or immunity-related genes (C) is presented \( (p < 0.00001) \). The solid line represents a positive correlation, while the dotted line represents a negative correlation.

within the first exon of the gene \( EVX1 \), has an overlap of eight nucleotides with the \( EVX1 \) mRNA and promotes transcription of its neighbor gene by increasing the binding affinity of histone H3 lysine 4 tri-methylation (H3K4me3) and histone H3 lysine 4 acetylation (H3K27ac) at the promoter region. Considering that most lncRNAs might function through their secondary structure rather than the primary one, this suggests that the regulation of antisense transcripts by antisense-overlapping lncRNA may not be mediated through base-complementary pairing.

Correlation analysis of DE lncRNA and protein-coding genes identified a number of DE lncRNA-DE protein-coding gene pairs. The main enriched KEGG pathways of these protein-coding genes were in metabolism and oxidative phosphorylation. In a recent report, 5-day-old neonatal pigs were infected with PDCoV, and transcriptome profile and KEGG pathway enrichment analysis were performed at different stages of infection (Wu et al., 2019). In our study, we found that the lncRNA targeted genes enriched in those pathways that were perturbed during the late stage of infection. In addition, the expression level of transglutaminase 3 (TGM3) and apolipoprotein A-2 (APOA2) in a Wu et al. (2019) study were significantly changed. Similarly, we also found that TGM1 was up-regulated, and APOA1, APOA4, and APOA5 were down-regulated during PDCoV infection (data not shown). Moreover, our data show that many cytokines and chemokines, which elicit an inflammatory response, were differentially expressed in the infected cells compared to mock cells. The inflammation causes injury to the intestinal tissues, resulting in diarrhea or even death. Raised CCL and CXCL10 levels were associated with the severity of virus infection (Betakova et al., 2017; Masood et al., 2018). Here, we identified a number of lncRNAs that may regulate the expression of these inflammatory molecules.

To the best of our knowledge, this is the first study focusing on the expression profile of cellular lncRNAs after PDCoV infection. Our data show the expression landscape of lncRNAs, with special emphasis on the lncRNA-protein modules
operating in response to PDCoV infection. Moreover, this study provides a comprehensive genome-wide resource for exploring the molecular and cellular regulatory functions of IncRNAs. This study will also be useful for identifying IncRNAs as potential biomarkers for the diagnosis of PDCoV infection and designing better prophylactic and therapeutic tools against virus infection.

CONCLUSION

In the present study, the expression profiles of IncRNAs were determined in PDCoV-infected ST cells. In total, 1,190 novel IncRNAs were identified. A total of 830 IncRNAs were differentially expressed between PDCoV-infected or mock-infected ST cells. KEGG pathway analysis of DE IncRNA co-expressed genes revealed that they might be primarily involved in regulating metabolism and TNF signaling pathways. Our study systematically characterizes IncRNA expression during PDCoV infection and provides a useful resource for identifying and functionally characterizing the cognate gene products of those IncRNAs. This study will also be useful for assigning IncRNAs as potential biomarkers of PDCoV infection and designing better preventive and therapeutic measures against the virus infection, which would be economically beneficial for the pig farming community.
