Abstract. We study quantum integrable $GL(3)$-based models with a trigonometric $R$-matrix solvable by the nested algebraic Bethe ansatz. We derive a determinant representation for a special case of scalar products of Bethe vectors. This representation allows one to find a determinant formula for the form factor of one of the monodromy matrix entries. We also point out an essential difference between form factors in the models with the trigonometric $R$-matrix and their analogs in $GL(3)$-invariant models.

Keywords: correlation functions, form factors, quantum integrability (Bethe Ansatz)

ArXiv ePrint: 1501.06253
1. Introduction

The algebraic Bethe ansatz [1–4] allows one to obtain the spectra of the quantum Hamiltonians of many models of physical interest. The calculation of correlation functions and form factors also can be performed within the framework of this method. The last problem in many cases can be reduced to the calculation of the scalar products of Bethe vectors. A systematic study of scalar products in quantum integrable $GL(3)$-based models with a trigonometric $R$-matrix [5,6] was initiated in [7,8].

Recently, the form factors of the monodromy matrix entries in models with $GL(3)$-invariant $R$-matrix were studied in works [9–13]. These form factors can be used for calculating correlation functions in a wide class of Bethe ansatz solvable models. It was shown in [13] that all the form factors of the monodromy matrix entries are related to each other. Actually, it is enough to calculate only one of them. All the others can be...
Scalar products in $GL(3)$-based models with trigonometric $R$-matrix. Determinant representation

obtained from this initial one within the special limits of Bethe parameters. This method was developed in [13], where it was called a zero modes method. In fact, this method allows one to obtain all the form factors from a scalar product of Bethe vectors of a special type.

A question arises about a generalization of these results to the models with trigonometric (or $q$-deformed) $R$-matrix. The trigonometric quantum $R$-matrix for the $GL(3)$-based models has the following form:

$$ R(u, v) = f(u, v) \sum_{1 \leq i \leq 3} E_{ii} \otimes E_{ii} + \sum_{1 \leq i < j \leq 3} (E_{ii} \otimes E_{jj} + E_{jj} \otimes E_{ii}) $$

\begin{align*}
&+ \sum_{1 \leq i < j \leq 3} (u g(u, v) E_{ij} \otimes E_{ji} + v g(u, v) E_{ji} \otimes E_{ij}),
\end{align*}

(1.1)

where the rational functions $f(u, v)$ and $g(u, v)$ are:

$$ f(u, v) = \frac{qu - q^{-1}v}{u - v}, \quad g(u, v) = \frac{q - q^{-1}}{u - v}, $$

(1.2)

and $q$ is a complex number (a deformation parameter). The matrices $(E_{ij})_{lk} = \delta_{il} \delta_{jk}$, $i, j, l, k = 1, 2, 3$ of the size $3 \times 3$ have a unit in the intersection of the $i$th row and $j$th column and zero matrix elements elsewhere.

For the $GL(2)$-based models $q$-deformation of the $R$-matrix does not lead to serious problems in calculating the scalar products of Bethe vectors. In particular, there exists a universal determinant representation for the scalar product of an arbitrary Bethe vector with an eigenstate of the transfer matrix [14]. Being written in terms of the functions (1.2) this representation is valid both for the models with $GL(2)$-invariant $R$-matrix and for the models with the $q$-deformed symmetry. In the first case one should only take the scaling limit in (1.2): $u = 1 + \epsilon u'$, $v = 1 + \epsilon v'$, $q = 1 + \epsilon c/2$, $\epsilon \to 0$.

One could expect that this similarity is preserved in the models described by the $q$-deformation of higher rank algebras. This expectation was partly confirmed in the recent works devoted to the analysis of scalar products in the $GL(3)$-based models with the trigonometric $R$-matrix [7, 8]. In particular, there was obtained a $q$-deformed generalization of the sum formula [15] for the scalar product of generic Bethe vectors. In this representation the scalar products are given as sums over partitions of the sets of Bethe parameters. It is known, however, that this type of representations are not convenient either for the analytical calculations of correlation functions or for their numeric analysis. It would be desirable to reduce the sums over partitions of Bethe parameters to determinant formulas similar to the ones obtained in [9–13] for the models with $GL(3)$-invariant $R$-matrix. The main goal of this paper is to obtain these representations.

To our great surprise it turned out that the $q$-deformation of $GL(3)$-invariance leads to significant changes at the level of determinant representations for form factors. In the present paper we obtain this representation for a form factor of only one entry of the monodromy matrix. Furthermore, we show that obtaining determinant representations for other form factors is impossible, at least within the framework of the scheme considered below. Instead, one can derive determinant formulas for so-called twisted form factors, where one of the vectors is an eigenstate of a twisted transfer matrix (see section 4) with a special twist parameter.
The paper is organized as follows. In section 2 we describe the model under consideration and introduce a necessary notation. Section 3 is devoted to the description of Bethe vectors and their scalar products. In section 4 we introduce a notion of a twisted transfer matrix that we use for calculating form factors. In section 5 we present the main result of the paper: a determinant representation for a special type of the scalar product of Bethe vectors in the $GL(3)$-based models with the trigonometric $R$-matrix. The remaining part of the paper is devoted to the proof of these formulas. In section 6 we describe some properties of the Izergin determinant and formulate several lemmas used in the next sections. In sections 7 and 8 we derive a determinant formula for the scalar product of twisted on-shell and usual on-shell Bethe vectors. Section 9 is devoted to the conclusive discussions. Appendices A and B contain the proofs of the lemmas formulated in section 6.

2. Notation

In this paper we consider quantum integrable models with a $3 \times 3$ monodromy matrix $T(u)$. It satisfies standard commutation relation ($RTT$-relation):

$$R(u, v) \cdot (T(u) \otimes 1) \cdot (1 \otimes T(v)) = (1 \otimes T(v)) \cdot (T(u) \otimes 1) \cdot R(u, v).$$  

(2.1)

The entries $T_{ij}(u)$ of the monodromy matrix act in a quantum space $V$ and form the quadratic algebra with commutation relations given by (2.1). We assume that the vector space $V$ possesses a highest weight vector $|0\rangle \in V$ such that:

$$T_{ij}(u)|0\rangle = 0, \quad i > j, \quad T_{ii}(u)|0\rangle = \lambda_i(u)|0\rangle, \quad \lambda_i(u) \in \mathbb{C}[u, u^{-1}].$$  

(2.2)

We also assume that the operators $T_{ij}(u)$ act in a dual space $V^*$ with a vector $\langle 0 | \in V^*$ such that:

$$\langle 0 | T_{ij}(u) = 0, \quad i < j, \quad \langle 0 | T_{ii}(u) = \lambda_i(u)\langle 0 |,$$  

(2.3)

and $\lambda_i(u)$ are the same as in (2.2). Actually, it is always possible to normalize the monodromy matrix $T(u) \to \lambda_2^{-1}(u)T(u)$ so as to deal only with the ratios

$$r_1(u) = \frac{\lambda_1(u)}{\lambda_2(u)}, \quad r_3(u) = \frac{\lambda_3(u)}{\lambda_2(u)}.$$  

(2.4)

Below we assume that $\lambda_2(u) = 1$.

Apart from the functions $g(x, y)$ and $f(x, y)$ (1.2) we also use two other auxiliary functions

$$h(x, y) = \frac{f(x, y)}{g(x, y)} = \frac{qx - q^{-1}y}{q - q^{-1}}, \quad t(x, y) = \frac{g(x, y)}{h(x, y)} = \frac{(q - q^{-1})^2}{(x - y)(qx - q^{-1}y)}.$$  

(2.5)

The following obvious properties of the functions introduced above are useful:

$$h(xq^{-2}, y) = q^{-1}g^{-1}(x, y), \quad g(x, yq^{-2}) = qh^{-1}(x, y), \quad g(xq^{-2}, x) = -qx^{-1}, \quad t(xq^{-2}, y) = q^2t(y, x), \quad t(x, yq^2) = q^{-2}t(y, x), \quad f(xq^{-2}, y) = f^{-1}(y, x).$$  

(2.6)

Below we permanently deal with sets of variables and their partitions into subsets. We denote sets of variables by bar: $\bar{u}$, $\bar{v}$ and so on,

$$\bar{u} = \{u_1, \ldots, u_n\}, \quad \bar{v} = \{v_1, \ldots, v_k\}.$$  

(2.7)

If necessary, the cardinalities of the sets are described in special comments after the formulas. The individual elements of the sets are denoted by subscripts: $u_j$, $v_k$ etc. Special
Scalar products in $GL(3)$-based models with trigonometric $R$-matrix. Determinant representation

notation $\bar{u}_j$, $\bar{v}_k$ and similar ones are used for subsets with one element omitted: $\bar{u}_j = \bar{u} \setminus u_j$, $\bar{v}_k = \bar{v} \setminus v_k$ and so on.

If a set of variables is multiplied by a number $\alpha \bar{u}$ (in particular, $\bar{u}q^{\pm 2}$), then it means that all the elements of the set are multiplied by this number:

$$\alpha \bar{u} = \{\alpha u_1, \ldots, \alpha u_n\}, \quad \bar{u}q^{\pm 2} = \{v_1q^{\pm 2}, \ldots, v_kq^{\pm 2}\}.$$ (2.8)

If the order of the elements in a set is essential, then we assume that the elements are ordered in such a way that the sequence of their subscripts is strictly increasing. We call this ordering a natural order.

A union of sets is denoted by braces, for example, $\{\bar{w}, \bar{u}\} = \bar{\eta}$. Partitions of sets into disjoint subsets are denoted by the symbol $\Rightarrow$, and the subsets are numerated by roman numerals. For example, notation $\bar{u} \Rightarrow \{\bar{u}_1, \bar{u}_2\}$ means that the set $\bar{u}$ is divided into two subsets $\bar{u}_1$ and $\bar{u}_2$, such that $\bar{u}_1 \cap \bar{u}_2 = \emptyset$ and $\{\bar{u}_1, \bar{u}_2\} = \bar{u}$. Similarly, notation $\bar{\eta} \Rightarrow \{\bar{\eta}_1, \bar{\eta}_2, \bar{\eta}_3\}$ means that the set $\bar{\eta}$ is divided into three subsets with pair-wise empty intersections and $\{\bar{\eta}_1, \bar{\eta}_2, \bar{\eta}_3\} = \bar{\eta}$.

Just like in [7] we use a shorthand notation for products with respect to sets of variables:

$$T_{ij}(\bar{w}) = \prod_{u \in \bar{w}} T_{ij}(w_k); \quad r_1(\bar{v}_k) = \prod_{v_j \in \bar{v}} r_1(v_j); \quad r_3(\bar{v}_j) = \prod_{v_j \in \bar{v}} r_3(v_j).$$ (2.9)

That is, if the operator $T_{ij}$ or the functions $r_k$ depend on a set of variables, this means that one should take the product of the operators or the scalar functions with respect to the corresponding set. The same convention will be used for the products of functions $f(u, v), h(u, v)$, and $t(u, v)$:

$$h(u, \bar{w}) = \prod_{u_j \in \bar{w}} h(u, w_j); \quad t(\bar{v}_k, u) = \prod_{v_j \in \bar{v}} t(v_j, u); \quad f(\bar{u}_1, \bar{u}_2) = \prod_{u_j \in \bar{u}_1} \prod_{v_k \in \bar{v}_2} f(u_j, v_k).$$ (2.10)

In addition to the standard shorthand notations we will also use

$$p(\bar{x}) = \prod_{x_k \in \bar{x}} x_k$$ (2.11)

### 3. Bethe vectors

Bethe vectors are special polynomials in the operators $T_{jk}(w)$ with $j < k$ applied to the vector $\ket{0}$. Similarly, dual Bethe vectors are special polynomials in the operators $T_{jk}(w)$ with $j > k$ applied to $\ket{0}$. Their explicit form in the $GL(N)$-based models with the trigonometric $R$-matrix was found in [16]. We denote Bethe vectors and their dual ones respectively by $\mathbb{B}^{a,b}(\bar{u}; \bar{v})$ and $\mathbb{C}^{a,b}(\bar{u}; \bar{v})$, stressing that they depend on two sets of variables $\bar{u}$ and $\bar{v}$. These variables are called Bethe parameters. The superscripts $a$ and $b$ show the cardinalities of the sets $\bar{u}$ and $\bar{v}$: $\# \bar{u} = a$, $\# \bar{v} = b$.

A Bethe vector$^1$ becomes an eigenvector of the transfer matrix $\text{tr} T(u)$ if the Bethe parameters satisfy a system of Bethe equations

$$r_1(u_j) = \frac{f(u_j, \bar{u})}{f(\bar{u}, u_j)} f(\bar{v}, u_j), \quad r_3(v_j) = \frac{f(\bar{v}, v_j)}{f(v_j, \bar{v})} f(v_j, \bar{u}),$$ (3.1)

$^1$ For simplicity below we do not distinguish between Bethe vectors and dual ones, if it does not cause a misunderstanding.

doi:10.1088/1742-5468/2015/03/P03019
and we recall that \( \bar{u}_j = u_j \setminus \bar{u}_i \), \( \bar{v}_j = v_j \setminus \bar{v}_i \). In this case we call the corresponding vector on-shell Bethe vector. Observe that if \( \bar{u} \) and \( \bar{v} \) satisfy (3.1), then for arbitrary partitions \( \bar{u} \Rightarrow \{ \bar{u}_1, \bar{u}_2 \} \) and \( \bar{v} \Rightarrow \{ \bar{v}_1, \bar{v}_2 \} \)

\[
\begin{align*}
  r_1(\bar{u}_1) &= \frac{f(\bar{u}_1, \bar{u}_2)}{f(\bar{u}_2, \bar{u}_1)} f(\bar{v}, \bar{u}_1), \\
  r_2(\bar{v}_1) &= \frac{f(\bar{v}_1, \bar{v}_2)}{f(\bar{v}_2, \bar{v}_1)} f(\bar{v}_1, \bar{u}).
\end{align*}
\] (3.2)

To obtain (3.2) it is enough to take the products in (3.1) with respect to the subsets \( \bar{u}_i \) and \( \bar{v}_i \).

If the system of Bethe equations (3.1) holds, then

\[
\text{tr} T(w) \mathbb{B}^{a,b}(\bar{u}; \bar{v}) = \tau(w|\bar{u}, \bar{v}) \mathbb{B}^{a,b}(\bar{u}; \bar{v}), \\
\mathbb{C}^{a,b}(\bar{u}; \bar{v}) \text{tr} T(w) = \tau(w|\bar{u}, \bar{v}) \mathbb{C}^{a,b}(\bar{u}; \bar{v}),
\] (3.3)

where

\[
\tau(w|\bar{u}, \bar{v}) = r_1(w) f(\bar{w}, \bar{u}) + f(w, \bar{u}) f(\bar{v}, \bar{w}) + r_3(w) f(w, \bar{v}).
\] (3.4)

Scalar products of Bethe vectors are defined as follows:

\[
S_{a,b} \equiv S_{a,b}(\bar{u}^c, \bar{v}^c; \bar{u}^b, \bar{v}^b) = \mathbb{C}^{a,b}(\bar{u}^c; \bar{v}^c) \mathbb{B}^{a,b}(\bar{u}^b; \bar{v}^b).
\] (3.5)

Here the vectors \( \mathbb{C}^{a,b}(\bar{u}^c; \bar{v}^c) \) and \( \mathbb{B}^{a,b}(\bar{u}^b; \bar{v}^b) \) are supposed to be generic Bethe vectors, i.e. their Bethe parameters are generic complex numbers. We have added the superscripts \( C \) and \( B \) to the sets \( \bar{u}, \bar{v} \) in order to stress that the vectors \( \mathbb{C}^{a,b}(\bar{u}^c; \bar{v}^c) \) and \( \mathbb{B}^{a,b}(\bar{u}^b; \bar{v}^b) \) may depend on different sets of parameters. In other words, unless explicitly specified, the variables \( \{ \bar{u}^a, \bar{v}^a \} \) in \( \mathbb{B}^{a,b} \) and \( \{ \bar{u}^c, \bar{v}^c \} \) in \( \mathbb{C}^{a,b} \) are not supposed to be equal.

The main goal of this paper is to find determinant representations for form factors of the diagonal entries \( \mathbb{T}_{\bar{u}}(z) \) of the monodromy matrix. We denote them by \( \mathcal{F}^{(i,i)}_{a,b}(z) \) and define as

\[
\mathcal{F}^{(i,i)}_{a,b}(z) \equiv \mathcal{F}^{(i,i)}_{a,b}(z|\bar{u}^c, \bar{v}^c; \bar{u}^b, \bar{v}^b) = \mathbb{C}^{a,b}(\bar{u}^c; \bar{v}^c) \mathbb{T}_{\bar{u}}(z) \mathbb{B}^{a,b}(\bar{u}^b; \bar{v}^b),
\] (3.6)

where both \( \mathbb{C}^{a,b}(\bar{u}^c; \bar{v}^c) \) and \( \mathbb{B}^{a,b}(\bar{u}^b; \bar{v}^b) \) are on-shell Bethe vectors. The parameter \( z \) is an arbitrary complex number.

4. Twisted transfer matrix

One can easily relate the form factors of the diagonal matrix elements \( \mathbb{T}_{\bar{u}}(z) \) with scalar products of a special type [9, 10, 17–19]. For this we introduce the notion of a twisted monodromy matrix and a twisted transfer matrix.

Let \( \bar{\kappa} \) be a set of three complex numbers (twist parameters) \( \bar{\kappa} = \{ \kappa_1, \kappa_2, \kappa_3 \} \). We define the twisted monodromy matrix as \( \mathbb{T}_{\bar{\kappa}} = \bar{\kappa} \mathbb{T} \), where \( \bar{\kappa} = \text{diag}(\kappa_1, \kappa_2, \kappa_3) \). It is easy to check that the tensor square of \( \bar{\kappa} \) commutes with the \( R \)-matrix: \( [\bar{\kappa}_1 \bar{\kappa}_2, R_{12}(u, v)] = 0 \), and therefore the twisted monodromy matrix satisfies the algebra (2.1)

\[
R(u, v) \cdot (T_{\bar{\kappa}}(u) \otimes 1) \cdot (1 \otimes T_{\bar{\kappa}}(v)) = (1 \otimes T_{\bar{\kappa}}(v)) \cdot (T_{\bar{\kappa}}(u) \otimes 1) \cdot R(u, v).
\] (4.1)

Thus, the eigenvectors of the twisted transfer matrix \( \text{tr} T_{\bar{\kappa}}(u) \) can be found within the framework of the standard scheme. We call them twisted (dual) on-shell Bethe vectors. Like the standard on-shell vectors, they can be parameterized by sets of complex parameters satisfying twisted Bethe equations

\[
\begin{align*}
  r_1(u_j) &= \frac{\kappa_2 f(u_j, \bar{u}_j)}{\kappa_1 f(u_j, \bar{u}_j)} f(\bar{v}, u_j), \\
  r_3(v_j) &= \frac{\kappa_3 f(v_j, \bar{u})}{\kappa_2 f(v_j, \bar{u})} f(v_j, \bar{u}).
\end{align*}
\] (4.2)

doi:10.1088/1742-5468/2015/03/P03019

J. Stat. Mech. (2015) P03019
Scalar products in $GL(3)$-based models with trigonometric $R$-matrix. Determinant representation

Similarly to (3.2) one can find for arbitrary partitions $\bar{u} \Rightarrow \{\bar{u}_i, \bar{u}_n\}$ and $\bar{v} \Rightarrow \{\bar{v}_i, \bar{v}_n\}$

$$r_1(\bar{u}_i) = \left(\frac{\kappa_2}{\kappa_1}\right)^{k_i} \frac{f(\bar{u}_i, \bar{u}_n)}{f(\bar{u}_n, \bar{u}_i)} f(\bar{v}, \bar{u}_i), \quad r_3(\bar{v}_i) = \left(\frac{\kappa_2}{\kappa_3}\right)^{n_i} \frac{f(\bar{v}_n, \bar{v}_i)}{f(\bar{v}_i, \bar{v}_n)} f(\bar{v}, \bar{v}_i),$$

(4.3)

where $k_i = \# \bar{u}_i$ and $n_i = \# \bar{v}_i$.

In this paper we will also consider twisted form factors. They are still defined by (3.6), but one of the vectors (for instance, $\mathbb{C}^{a,b}(\bar{u}^C; \bar{v}^C)$) is a twisted on-shell Bethe vector. Calculating the twisted and usual form factors of the matrix elements $T_{ii}(z)$ can be reduced to the scalar products via the following method.

Let $\text{tr} \ T(z)$ be the twisted transfer matrix and $\text{tr} \ T(z)$ be the standard transfer matrix. Consider

$$Q_\kappa(z) = \mathbb{C}^{a,b}(\bar{u}^C; \bar{v}^C)(\text{tr} \ T_\kappa(z) - \text{tr} \ T(z))\mathbb{B}^{a,b}(\bar{u}^a; \bar{v}^b),$$

(4.4)

where $\mathbb{C}^{a,b}(\bar{u}^C; \bar{v}^C)$ and $\mathbb{B}^{a,b}(\bar{u}^a; \bar{v}^b)$ are twisted and standard on-shell vectors, respectively. Obviously

$$Q_\kappa(z) = \mathbb{C}^{a,b}(\bar{u}^C; \bar{v}^C) \sum_{j=1}^{3} (\kappa_j - 1) T_{jj}(z) \mathbb{B}^{a,b}(\bar{u}^b; \bar{v}^a).$$

(4.5)

Let $i$ be a fixed number from the set $\{1, 2, 3\}$, and let $\kappa_i = 1$ (that is $\kappa_j = 1$ for $j \neq i$). Then we obtain

$$\mathcal{F}^{(i,j)}_{a,b,\kappa_i}(z|\bar{u}^C, \bar{v}^C; \bar{u}^b, \bar{v}^a) = \frac{Q_\kappa(z)}{\kappa_i - 1},$$

(4.6)

where $\mathcal{F}^{(i,j)}_{a,b,\kappa_i}(z)$ denotes a twisted form factor corresponding to the twist parameters $\kappa_i = 1$.

On the other hand

$$Q_\kappa(z) = (\tau_\kappa(z|\bar{u}^C; \bar{v}^C) - \tau(z|\bar{u}^b; \bar{v}^a)) \mathbb{C}^{a,b}(\bar{u}^C; \bar{v}^C)\mathbb{B}^{a,b}(\bar{u}^a; \bar{v}^b),$$

(4.7)

where $\tau_\kappa(z|\bar{u}^C; \bar{v}^C)$ is the eigenvalue of the twisted transfer matrix on the vector $\mathbb{C}^{a,b}(\bar{u}^C; \bar{v}^C)$;

$$\tau_\kappa(z|\bar{u}^C; \bar{v}^C) = \kappa_1 r_1(z) f(\bar{u}^C, z) + \kappa_2 f(z, \bar{u}^C) f(\bar{v}, z) + \kappa_3 r_3(z) f(z, \bar{v}^C).$$

(4.8)

Thus, we arrive at

$$\mathcal{F}^{(i,j)}_{a,b,\kappa_i}(z|\bar{u}^C, \bar{v}^C; \bar{u}^b, \bar{v}^a) = \frac{\tau_\kappa(z|\bar{u}^C; \bar{v}^C) - \tau(z|\bar{u}^b; \bar{v}^a)}{\kappa_i - 1} \mathbb{C}^{a,b}(\bar{u}^C; \bar{v}^C)\mathbb{B}^{a,b}(\bar{u}^a; \bar{v}^b).$$

(4.9)

In the limit $\kappa_i \rightarrow 1$ we obtain the usual form factor of $T_{ii}(z)$ [9, 10, 17]

$$\mathcal{F}^{(i,j)}_{a,b}(z|\bar{u}^C, \bar{v}^C; \bar{u}^b, \bar{v}^a) = \frac{d}{d\kappa_i} \left(\tau_\kappa(z|\bar{u}^C; \bar{v}^C) - \tau(z|\bar{u}^b; \bar{v}^a)\right) |_{\kappa_i = 1}^{\kappa_i = 1} \mathbb{C}^{a,b}(\bar{u}^C; \bar{v}^C)\mathbb{B}^{a,b}(\bar{u}^a; \bar{v}^b).$$

(4.10)

Here the symbol $\kappa = 1$ means that $\kappa_j = 1$, $j = 1, 2, 3$. Thus, evaluating twisted and usual form factors is reduced to the computation of the scalar product between the twisted and usual on-shell Bethe vectors.

5. Main results

We obtain determinant representations for the scalar product of the twisted and usual on-shell Bethe vectors in two cases: $\kappa_3/\kappa_1 = 1$ and $\kappa_3/\kappa_1 = q^2$. In both cases $\kappa_2$ remains
an arbitrary complex number. We denote the corresponding scalar products by $S_{a,b}^{(1)}$ and $S_{a,b}^{(q^2)}$, respectively. In order to describe determinant representations we first introduce for an arbitrary set of variables $\vec{w} = \{w_1, \ldots, w_n\}$

$$
\Delta_n(\vec{w}) = \prod_{j>k}^n g(w_j, w_k), \quad \Delta'_n(\vec{w}) = \prod_{j<k}^n g(w_j, w_k).
$$

Let also

$$
C_h = h(\vec{v}^c, \vec{v}^c) h(\vec{v}^b, \vec{u}^b). \tag{5.2}
$$

Then we introduce an $a \times (a + b)$ matrix $N^{(u)}(u^c_j, x_k)$

$$
N^{(u)}(u^c_j, x_k) = (-1)^{a-1} t(u^c_j, x_k) \frac{r_1(x_k)}{\det(h(\vec{v}^c, x_k) h(x_k, \vec{u}^b))} + \frac{\kappa_2}{\kappa_1} t(x_k, u^c_j) \frac{h(x_k, \vec{u}^c)}{h(x_k, \vec{u}^b)}, \tag{5.3}
$$

and a $b \times (a + b)$ matrix $N^{(v)}(v^b_j, x_k)$

$$
N^{(v)}(v^b_j, x_k) = (-1)^{b-1} t(x_k, v^b_j) \frac{r_3(x_k)}{\det(h(\vec{v}^c, x_k) h(x_k, \vec{u}^b))} + t(v^b_j, x_k) \frac{h(\vec{v}^b, x_k)}{h(\vec{v}^c, x_k)}. \tag{5.4}
$$

In these formulas

$$
\vec{x} = \{\vec{u}^b, \vec{v}^c\} = \{u_1^b, \ldots, u_a^b, v_1^c, \ldots, v_b^c\}. \tag{5.5}
$$

**Proposition 5.1.** The determinant representation for $S_{a,b}^{(1)}$ has the following form:

$$
S_{a,b}^{(1)} = p(\vec{v}^b) p(\vec{u}^b) C_h \Delta'_a(\vec{u}^c) \Delta'_b(\vec{v}^b) \Delta_{a+b}(\vec{x}) \det N, \tag{5.6}
$$

where

$$
N_{j,k} = N^{(u)}(u^c_j, x_k), \quad j = 1, \ldots, a,
N_{j+a,k} = N^{(v)}(v^b_j, x_k), \quad j = 1, \ldots, b, \quad \{x_1, \ldots, x_{a+b}\} = \{u_1^b, \ldots, u_a^b, v_1^c, \ldots, v_b^c\}. \tag{5.7}
$$

Comparing this result with the analogous scalar product in the models with $GL(3)$-invariant $R$-matrix [9] we see that up to the trivial prefactor $p(\vec{v}^b) p(\vec{u}^b)$ it has exactly the same form. One should simply replace the rational functions $g(u, v), f(u, v), h(u, v)$, and $t(u, v)$ by their analogs in $GL(3)$-invariant models:

$$
g(u, v) \rightarrow g^{(0)}(u, v) = \frac{c}{u-v}, \quad f(u, v) \rightarrow f^{(0)}(u, v) = \frac{u-v+c}{u-v}, \quad h(u, v) \rightarrow h^{(0)}(u, v) = \frac{u-v+c}{u-v}, \quad t(u, v) \rightarrow t^{(0)}(u, v) = \frac{(u-v)(u-v+c)}{(u-v)(u-v+c)}, \tag{5.8}
$$

where $c$ is a constant. This correspondence is quite similar to the one that we have for the $GL(2)$ case.

Similarly to (5.7) we define a matrix $\tilde{N}$ as

$$
\tilde{N}_{j,k} = x_k N^{(u)}(u^c_j, x_k), \quad j = 1, \ldots, a,
\tilde{N}_{j+a,k} = N^{(v)}(v^b_j, x_k), \quad j = 1, \ldots, b. \tag{5.9}
$$

**Proposition 5.2.** The determinant representation for $S_{a,b}^{(q^2)}$ has the following form:

$$
S_{a,b}^{(q^2)} = p(\vec{v}^b) C_h \Delta'_a(\vec{u}^c) \Delta'_b(\vec{v}^b) \Delta_{a+b}(\vec{x}) \det \tilde{N}. \tag{5.10}
$$

doi:10.1088/1742-5468/2015/03/P03019
It is clear that in the scaling limit $q \to 1$ representations (5.10) and (5.6) coincide and give the determinant formula for the scalar product of the twisted and usual on-shell vectors in the models with $GL(3)$-invariant $R$-matrix [9].

Remark. The matrix elements $N^{(a)}(u^c_a, x_k)$ (5.3) and $N^{(v)}(v^b_a, x_k)$ (5.4) require additional definition if $\bar{a}_C \cap \bar{a}_B \neq \emptyset$ or $\bar{v}_C \cap \bar{v}_B \neq \emptyset$. Let for definiteness $u^c_a = u^B_a$. The matrix element $N^{(a)}(u^c_a, u^B_a)$ depends on the functions $u^c_a$ and $u^B_a$, which have a pole at $u^B_a = u^c_a$. However, one can easily check that the residue in this pole vanishes due to the twisted Bethe equations (4.2), and hence, the limit of (5.3) is finite:

$$N^{(a)}(u^c_a, u^B_a)\bigg|_{u^c_a=u^B_a} = \frac{\kappa_2}{\kappa_1 u^c_a} \frac{h(u^c_a, \bar{u}^c)}{h(\bar{u}^c, \bar{u}^B)} \left[ (q^{-1} - q) \frac{r'_1(u^c_a)}{r_1(u^c_a)} \right] + \sum_{t=1}^{a-1} \frac{(q + q^{-1})u^c_t}{h(u^c_t, u^c_a)} + \sum_{i=1}^{b} v^b_i \tau_i(u^c_a, u^B_a), \tag{5.11}$$

where $r'_1(u^c_a)$ is the derivative of $r_1(u^c_a)$. It is this expression for $N^{(a)}(u^c_a, u^B_a)$ that needs to be used in the case $u^c_a = u^B_a$. Similarly, if $v^b_a = v^B_a$, then

$$N^{(v)}(v^B_a, v^B_a)\bigg|_{v^B_a=v^B_a} = \frac{1}{v^B_a} \frac{h(\bar{v}^B_a, v^B_a)}{h(v^B_a, \bar{v}^c)} \left[ (q^{-1} - q) \frac{r'_3(v^B_a)}{r_3(v^B_a)} \right] - \sum_{t=1}^{a-1} \frac{(q + q^{-1})v^B_t}{h(v^B_t, v^B_a)} + \sum_{i=1}^{b} u^B_i \tau_i(v^B_a, u^B_a), \tag{5.12}$$

where $r'_3(v^B_a)$ is the derivative of $r_3(v^B_a)$.

Note that in the particular case $\bar{u}^c = \bar{u}^B$, $\bar{v}^c = \bar{v}^B$, and $\bar{\kappa} = 1$ representation (5.6) for $S^{(1)}_{a,b}$ gives the square of the norm of the on-shell Bethe vector. In this case one should use (5.11) and (5.12) for the diagonal entries of the matrix $N$.

We would like to stress once more that in the obtained results the parameter $\kappa_2$ is an arbitrary complex number, while the ratio of the parameters $\kappa_1$ and $\kappa_3$ is fixed. Since the final result depends on the ratios of $\kappa_1$ only, one can say that $\kappa_1$ and $\kappa_3$ are fixed. This means that using (4.10) we can obtain a determinant representation for the form factor of the operator $T_{22}(z)$

$$\mathcal{F}^{(2,2)}(z|\bar{u}^c, \bar{v}^c; \bar{u}^B, \bar{v}^B) = \frac{d}{d\kappa_2} \left( \tau_\bar{\kappa}(z|\bar{u}^c, \bar{v}^c) - \tau(z|\bar{u}^B, \bar{v}^B) \right) S^{(1)}_{a,b}(\bar{u}^c, \bar{v}^c; \bar{u}^B, \bar{v}^B) \bigg|_{\kappa_2=1}. \tag{5.13}$$

However, we cannot obtain determinant representations for the form factors of the operators $T_{11}(z)$ and $T_{33}(z)$. For these operators we know only the twisted form factors with fixed values of the twist parameters, for example

$$\mathcal{F}^{(3,3)}(z|\bar{u}^c, \bar{v}^c; \bar{u}^B, \bar{v}^B) = \frac{\tau_\bar{\kappa}(z|\bar{u}^c, \bar{v}^c) - \tau(z|\bar{u}^B, \bar{v}^B)}{q^2 - 1} S^{(q^2)}_{a,b}(\bar{u}^c, \bar{v}^c; \bar{u}^B, \bar{v}^B), \tag{5.14}$$

where $\bar{\kappa} = \{1, 1, q^2\}$.

The remainder of this work is devoted to the proof of propositions 5.1 and 5.2.

6. Summation identities

The central object of the theory of scalar products in the $GL(2)$-based models is the Izergin determinant $K_{\bar{\kappa}}(\bar{x}|\bar{y})$ [20]. It also plays an important role in the case of the $GL(3)$-based...
models with trigonometric $R$-matrix. The Izergin determinant is defined for two sets $\bar{x}$ and $\bar{y}$ of the same cardinality $\#\bar{x} = \#\bar{y} = k$:

$$K_k(\bar{x}|\bar{y}) = \Delta'(\bar{x})\Delta(\bar{y}) h(\bar{x}, \bar{y}) \det t(x_i, y_j).$$

(6.1)

For further applications it is convenient to introduce two modifications of the Izergin determinant

$$K_k^{(l)}(\bar{x}|\bar{y}) = p(\bar{x})\cdot K_k(\bar{x}|\bar{y}), \quad K_k^{(r)}(\bar{x}|\bar{y}) = p(\bar{y})\cdot K_k(\bar{x}|\bar{y}),$$

(6.2)

which we call the left and right Izergin determinants, respectively.

For the derivation of determinant representations for scalar products we shall use several properties of the Izergin determinant. It is obvious that this rational function is symmetric over the set $\bar{x}$ and symmetric over the set $\bar{y}$. The Izergin determinant (6.1) vanishes if one of its arguments goes to infinity and the other arguments are fixed. Respectively, $K_k^{(l)}$ is bounded if $x_i \to \infty$, while $K_k^{(r)}$ is bounded if $y_i \to \infty$.

Several simple properties of the Izergin determinant follow directly from the definition (6.1). Their detailed proofs are given in [7]. A reduction property has the form

$$K_{n+m}^{(l,r)}(\{\bar{x}, q^2\bar{z}\}|\{\bar{y}, \bar{z}\}) = K_{n+m}^{(l,r)}(\{\bar{x}, \bar{z}\}|\{\bar{y}, q^2\bar{z}\}) = (-q)^{\mp m}K_n^{(l,r)}(\bar{x}|\bar{y}),$$

(6.3)

where $m = \#\bar{z}$ and $n = \#\bar{x} = \#\bar{y}$. Here the superscripts $(l, r)$ on $K$ mean that the equation is valid both for $K^{(l)}$ and for $K^{(r)}$ with an appropriate choice of component (first/upper or second/lower) throughout the equation.

A similar reduction of the Izergin determinant takes place in the poles of this function

$$K_{n+1}^{(l,r)}(\{\bar{x}, z\}|\{\bar{y}, z'\})|_{z' \to z} = f(z, z')f(z, \bar{y})f(\bar{x}, z)K_n^{(l,r)}(\bar{x}|\bar{y}) + \text{reg},$$

(6.4)

where reg means the regular part. One more simple property of $K_n^{(l,r)}$ is also useful

$$K_n^{(l,r)}(q^{-2}\bar{x}|\bar{y}) = K_n^{(l,r)}(\bar{x}|q^2\bar{y}) = (-q)^{\mp n}f^{-1}(\bar{y}, \bar{x})K_n^{(r,l)}(\bar{y}|\bar{x}).$$

(6.5)

More sophisticated properties of the Izergin determinant represent summation identities, in which the sum is taken over the partitions of one or more sets of variables.

**Lemma 6.1.** Let $\bar{\gamma}, \bar{\alpha}$ and $\bar{\beta}$ be three sets of complex variables with $\#\alpha = m_1$, $\#\beta = m_2$, and $\#\gamma = m_1 + m_2$. Then

$$\sum K_{m_1}^{(l,r)}(\bar{\gamma}_1|\bar{x})K_{m_2}^{(r,l)}(\bar{\beta}|\bar{\gamma}_2)f(\bar{\gamma}_1, \bar{\gamma}_2) = (-q)^{\mp m_1}f(\bar{\gamma}, \bar{x})K_{m_1+m_2}^{(r,l)}(\{\bar{\alpha}q^{-2}, \bar{\beta}\}|\bar{\gamma}).$$

The sum is taken with respect to all partitions of the set $\bar{\gamma} \Rightarrow \{\bar{\gamma}_1, \bar{\gamma}_2\}$ with $\#\bar{\gamma}_1 = m_1$ and $\#\bar{\gamma}_2 = m_2$.

This lemma is a complete analog of lemma 1 of [9], where the reader can find the detailed proof.

**Lemma 6.2.** Let $\bar{\gamma}$ and $\bar{\xi}$ be two sets of generic complex numbers with $\#\bar{\gamma} = \#\bar{\xi} = m$. Let also $\phi_1(\gamma)$ and $\phi_2(\gamma)$ be two arbitrary functions of a complex variable $\gamma$. Then

$$\sum K_{m}^{(l,r)}(\{\bar{\gamma}_1q^{-2}, \bar{\gamma}_2\}|\bar{\xi})f(\bar{\xi}, \bar{\gamma}_1)f(\bar{\gamma}_2, \bar{\gamma}_1)\phi_1(\bar{\gamma}_1)\phi_2(\bar{\gamma}_2)$$

$$= p^{tr}\Delta_n(\bar{\xi})\Delta_m(\bar{\gamma})\det_{\gamma} (\phi_2(\gamma_k)t(\gamma_k, \xi_j)h(\gamma_k, \xi_j) + q^{\mp 1}(-1)^m\phi_1(\gamma_k)t(\xi_j, \gamma_k)h(\bar{\xi}, \gamma_k)).$$

(6.7)

Here $p^t = p(\bar{\gamma})$, $p^r = p(\bar{\xi})$, and we used the shorthand notation (2.9) for the products of the functions $\phi_1$ and $\phi_2$. The sum is taken over all possible partitions $\bar{\gamma} \Rightarrow \{\bar{\gamma}_1, \bar{\gamma}_2\}$.
This lemma is a trigonometric analog of lemma 2 of [9]. However, the proof contains small, but important differences. Therefore, we give this proof in appendix A.

**Lemma 6.3.** Let \( \bar{\alpha} \) and \( \bar{\beta} \) be two sets of generic complex numbers with \( \#\bar{\alpha} = \#\bar{\beta} = n \). Let \( z \) be an arbitrary complex number. Then
\[
\sum q^n f(\bar{\beta}, z) f(\bar{\alpha}, \bar{\alpha}) \mathcal{K}_{ni}^{(r)}(\bar{\beta}|\bar{\alpha}) \mathcal{K}_{nj}^{(l)}(\bar{\alpha}|\bar{\beta}) = q^n G_n(\bar{\alpha}|\bar{\beta}) h(\bar{\alpha}, \bar{\alpha}) h(\bar{\beta}, \bar{\beta}),
\]
where
\[
G_n(\bar{\alpha}|\bar{\beta}) = (-1)^n t(\bar{\alpha}, \bar{\beta}) h(\bar{\alpha}, \bar{\alpha}) h(\bar{\beta}, \bar{\beta}),
\]
and the sum is taken over all possible partitions \( \bar{\alpha} \Rightarrow \{\bar{\alpha}_1, \ldots, \bar{\alpha}_n\} \) and \( \bar{\beta} \Rightarrow \{\bar{\beta}_1, \ldots, \bar{\beta}_n\} \) with \( \#\bar{\alpha}_1 = \#\bar{\beta}_1 = n_1, n_i = 0, \ldots, n, \) and \( \#\bar{\alpha} = \#\bar{\beta} = n_n = n - n_1 \).

This lemma is a trigonometric analog of lemma A.3 of [11]. Due to the importance of this lemma we give the proof in appendix B.

The identity (6.8) has several particular cases.

**Corollary 6.1.** Let \( \bar{\alpha} \) and \( \bar{\beta} \) be two sets of generic complex numbers with \( \#\bar{\alpha} = \#\bar{\beta} = n \). Then
\[
\sum f(\bar{\beta}, \bar{\alpha}) f(\bar{\alpha}, \bar{\alpha}) \mathcal{K}_{ni}^{(r)}(\bar{\beta}|\bar{\alpha}) \mathcal{K}_{nj}^{(l)}(\bar{\alpha}|\bar{\beta}) = G_n(\bar{\alpha}|\bar{\beta}),
\]
and
\[
\sum q^{2n_2} f(\bar{\beta}, \bar{\alpha}) f(\bar{\alpha}, \bar{\alpha}) \mathcal{K}_{ni}^{(r)}(\bar{\beta}|\bar{\alpha}) \mathcal{K}_{nj}^{(l)}(\bar{\alpha}|\bar{\beta}) = \frac{p(\bar{\beta})}{p(\bar{\alpha})} G_n(\bar{\alpha}|\bar{\beta}).
\]

The sum is taken over all possible partitions \( \bar{\alpha} \Rightarrow \{\bar{\alpha}_1, \ldots, \bar{\alpha}_n\} \) and \( \bar{\beta} \Rightarrow \{\bar{\beta}_1, \ldots, \bar{\beta}_n\} \) with \( \#\bar{\alpha}_1 = \#\bar{\beta}_1 = n_1, n_i = 0, \ldots, m, \) and \( \#\bar{\alpha} = \#\bar{\beta} = n_n = n - n_1 \).

Identity (6.10) follows from (6.8) in the limit \( z \to \infty \). Identity (6.11) follows from (6.10) due to obvious relation
\[
\mathcal{K}_{ni}^{(r)}(\bar{\beta}|\bar{\alpha}) \mathcal{K}_{nj}^{(l)}(\bar{\alpha}|\bar{\beta}) = q^{2n_2} \frac{p(\bar{\alpha})}{p(\bar{\beta})} \mathcal{K}_{nj}^{(l)}(\bar{\beta}|\bar{\alpha}) \mathcal{K}_{ni}^{(r)}(\bar{\alpha}|\bar{\beta}).
\]

**Corollary 6.2.** Under the conditions of corollary 6.1
\[
\sum q^{2n_2} f(\bar{\beta}, \bar{\alpha}) f(\bar{\alpha}, \bar{\alpha}) \mathcal{K}_{ni}^{(r)}(\bar{\beta}|\bar{\alpha}) \mathcal{K}_{nj}^{(l)}(\bar{\alpha}|\bar{\beta}) = q^{2n_2} \frac{p(\bar{\alpha})}{p(\bar{\beta})} G_n(\bar{\alpha}|\bar{\beta}).
\]

Identity (6.13) follows from (6.8) in the limit \( z = 0 \). Identity (6.14) follows from (6.13) and (6.12).

**Corollary 6.3.** Under the conditions of corollary 6.1
\[
\sum q^n [n_1] f(\bar{\beta}, \bar{\alpha}) f(\bar{\alpha}, \bar{\alpha}) \mathcal{K}_{ni}^{(r)}(\bar{\beta}|\bar{\alpha}) \mathcal{K}_{nj}^{(l)}(\bar{\alpha}|\bar{\beta}) = \frac{q^{2n_2} \frac{p(\bar{\alpha})}{p(\bar{\beta})} - 1}{q - q^{-1}} G_n(\bar{\alpha}|\bar{\beta}).
\]

where \([n_1]\) means a \(q\)-number \([n_1] = (q^n - q^{-n})/(q - q^{-1})\).

This identity is a linear combination of (6.10) and (6.13).
7. Derivation of determinant representation

The derivation of a determinant representation for the scalar product of twisted on-shell and usual on-shell Bethe vectors is quite similar to the one given in [9] for GL(3)-invariant models. Nevertheless, in certain cases the \( q \)-deformation of the \( R \)-matrix leads to an essential difference in the final result. Therefore we give all the details of the derivation.

We start with the sum formula for the scalar product in the GL(3)-based models with the trigonometric \( R \)-matrix [8]:

\[
S_{a,b}(\bar{u}^C; \bar{v}^C | \bar{u}^B; \bar{v}^B) = \sum_{u} f(\bar{u}_a^B, \bar{u}_a^B) f(\bar{u}_a^C, \bar{u}_a^C) f(\bar{v}_a^B, \bar{v}_a^B) f(\bar{v}_a^C, \bar{v}_a^C) f(\bar{v}_a^B, \bar{v}_a^B) \times \frac{r_1(\bar{v}_a^C) r_1(\bar{u}_a^B) r_3(\bar{v}_a^C) r_3(\bar{u}_a^B)}{f(\bar{v}_a^C, \bar{u}_a^C)} Z_{a-k,n}^{(l)}(\bar{u}_a^B | \bar{v}_a^C; \bar{v}_a^C, \bar{v}_a^C) Z_{k-b-n}^{(r)}(\bar{u}_a^B; \bar{v}_a^B | \bar{v}_a^B, \bar{v}_a^B). \tag{7.1}
\]

The sum in (7.1) is taken over the partitions of the sets \( \bar{u}^C, \bar{u}^B, \bar{v}^C, \) and \( \bar{v}^B \)

\[
\bar{u}^C \Rightarrow \{ \bar{u}_1^C, \bar{u}_a^C \}, \quad \bar{v}^C \Rightarrow \{ \bar{v}_1^C, \bar{v}_a^C \}, \quad \bar{u}^B \Rightarrow \{ \bar{u}_1^B, \bar{u}_a^B \}, \quad \bar{v}^B \Rightarrow \{ \bar{v}_1^B, \bar{v}_a^B \}. \tag{7.2}
\]

The partitions are independent except that \( \# \bar{u}_a^B = \# \bar{u}_a^C = k \) with \( k = 0, \ldots, a \), and \( \# \bar{u}_1^B = \# \bar{u}_1^C = n \) with \( n = 0, \ldots, b \).

The functions \( Z_{a-k,n}^{(l)} \) and \( Z_{k-b-n}^{(r)} \) are the left and the right highest coefficients, respectively. They can be expressed in terms of the Izergin determinants [7]. We need two representations of these functions. The first one reads

\[
Z_{a-k,n}^{(l)}(\bar{t} ; \bar{x} | \bar{s} ; \bar{y}) = (-q)^{-a} f(\bar{y}, \bar{x}) f(\bar{s}, \bar{t}) \times \sum_{\bar{\eta}} K_a^{(r,j)}(\bar{x}q^2 | \bar{\eta}_q^2) K_a^{(l,r)}(\bar{\eta}_\theta^2 | \bar{\eta}_q^2) f(\bar{\eta}, \bar{\eta}), \tag{7.3}
\]

where \( \bar{w} = \{ \bar{x}, \bar{s} \} \). The sum is taken with respect to partitions of the set \( \bar{w} \Rightarrow \{ \bar{w}_1, \bar{w}_a \} \) with \( \# \bar{w}_1 = b \) and \( \# \bar{w}_a = a \). Similarly to the formulas of section 6 (see e.g. (6.6) and 6.2) the superscript \( (l, r) \) on \( Z_{a,b} \) means that equation (7.3) is valid for \( Z_{a,b}^{(l)} \) and for \( Z_{a,b}^{(r)} \) separately. Choosing the first or the second component in the pair \( (l, r) \) and the corresponding (up or down resp.) exponent of \( (-q)^{-k} \) in this equation, we obtain representations either for \( Z_{a,b}^{(l)}(\bar{t} ; \bar{x} | \bar{s} ; \bar{y}) \) or for \( Z_{a,b}^{(r)}(\bar{t} ; \bar{x} | \bar{s} ; \bar{y}) \).

The second representation for the highest coefficient has the following form:

\[
Z_{a,b}^{(l)}(\bar{t} ; \bar{x} | \bar{s} ; \bar{y}) = (-q)^{-a} f(\bar{y}, \bar{x}) f(\bar{s}, \bar{t}) \times \sum_{\bar{\eta}} K_a^{(r,j)}(\bar{x}q^2 | \bar{\eta}_q^2) K_a^{(l,r)}(\bar{\eta} | \bar{\eta}_q^2) K_b^{(l,r)}(\bar{\eta} | \bar{\eta}_ \theta^2) f(\bar{\eta}, \bar{\eta}), \tag{7.4}
\]

where \( \bar{\eta} = \{ \bar{y}, \bar{\eta}_q^{-2} \} \). The sum is taken with respect to partitions of the set \( \bar{\eta} \Rightarrow \{ \bar{\eta}_1, \bar{\eta}_a \} \) with \( \# \bar{\eta}_1 = a \) and \( \# \bar{\eta}_a = b \).

It is convenient to use one type of representations for \( Z_{a-k,n}^{(l)} \) and another type for \( Z_{k-b-n}^{(r)} \). For example, using (7.3) for \( Z_{a-k,n}^{(l)}(\bar{u}_a^C, \bar{u}_a^B | \bar{v}_a^C; \bar{v}_a^B) \) we obtain

\[
Z_{a-k,n}^{(l)}(\bar{u}_a^C, \bar{u}_a^B | \bar{v}_a^C; \bar{v}_a^B) = (-q)^{-n} \sum_{\bar{\eta}} K_{\bar{v}_a^C}^{(r)}(\bar{v}_a^C | \bar{\eta}_q^2) K_{\bar{u}_a^B}^{(l)}(\bar{u}_a^B | \bar{v}_a^C) K_{\bar{u}_a^C}^{(l)}(\bar{u}_a^C | \bar{v}_a^B) f(\bar{\eta}, \bar{\eta}), \tag{7.5}
\]

with \( \bar{w} = \{ \bar{u}_a^B, \bar{v}_a^C \} \). Thus, we obtain an additional sum over partitions of the sets \( \bar{u}_a^B \) and \( \bar{v}_a^C \) into sub-subsets, but we do not create additional sub-subsets of \( \bar{u}_a^C \) and \( \bar{u}_a^B \). Using now (7.4) for \( Z_{k-b-n}^{(r)}(\bar{u}_a^B, \bar{v}_a^B | \bar{v}_a^B) \) we obtain

\[
Z_{k-b-n}^{(r)}(\bar{u}_a^B, \bar{v}_a^B | \bar{v}_a^B) = (-q)^k f(\bar{v}_a^B, \bar{x}) f(\bar{s}, \bar{u}_a^B) \times \sum_{\bar{\eta}} K_k^{(l)}(\bar{u}_a^B | \bar{x}q^2, \bar{\eta}_q^2) K_k^{(r)}(\bar{v}_a^C | \bar{\eta}_q^2) K_{\bar{u}_a^B}^{(r)}(\bar{\eta}_1, \bar{\eta}_a) f(\bar{\eta}, \bar{\eta}), \tag{7.6}
\]
Scalar products in $GL(3)$-based models with trigonometric $R$-matrix. Determinant representation

with $\tilde{\eta} = \{ \tilde{v}_n^a, \tilde{u}_n^a q^{-2} \}$. Thus, we again create new sub-subsets of the sets $\tilde{u}^a$ and $\tilde{v}^c$, but we do not touch the original partitions of the sets $\tilde{u}^c$ and $\tilde{v}^a$. As a result we obtain a possibility to take the sum over partitions $\tilde{u}^c \Rightarrow \{ \tilde{u}_n^c, \tilde{u}_n^c \}$ and $\tilde{v}^c \Rightarrow \{ \tilde{v}_1^c, \tilde{v}_1^c \}$. Indeed, substituting into (7.1): (1) representations (7.5) and (7.6); (2) twisted Bethe equations (4.2) for the product of functions $r_1(\tilde{u}_n^c)$; (3) standard Bethe equations (3.1) for the product of functions $r_3(\tilde{v}_1^c)$; we obtain

$$S_{a,b}(\tilde{u}^c; \tilde{v}^c|\tilde{u}^a; \tilde{v}^a) = \sum (-q)^{k-n}\left( \frac{k_2}{k_1} \right)^{a-k} r_1(\tilde{u}_n^a)r_3(\tilde{v}_1^c)f(\tilde{u}_n^a, \tilde{u}_1^c)f(\tilde{v}_1^c, \tilde{v}_1^c)$$

$$\times f(\tilde{u}_n^a, \tilde{u}_1^c)f(\tilde{v}_1^c, \tilde{v}_1^c)K^{(r)}_n(\tilde{v}_1^c|\tilde{v}_1^c q^2)K^{(l)}_n(\tilde{u}_n^a|\tilde{u}_n^a)K^{(l)}_n(\tilde{v}_1^c|\tilde{w}_1)f(\tilde{w}_1, \tilde{w}_n)$$

$$\times K^{(l)}_k(\tilde{u}_n^a q^{-2}|\tilde{\eta} q^2)K^{(r)}_k(\tilde{\eta} q^2|\tilde{\eta} q^2)K^{(l)}_{a-k}(\tilde{\eta} q^2|\tilde{\eta} q^2)$$

(7.7)

Here the sum is taken over the partitions (7.2) and additional partitions

$$\{ \tilde{u}_n^a, \tilde{u}_1^c \} = \tilde{w} \Rightarrow \{ \tilde{w}_n, \tilde{w}_1 \},$$

$$\{ \tilde{v}_1^c, \tilde{u}_n^a q^{-2} \} = \tilde{\eta} \Rightarrow \{ \tilde{\eta}_n, \tilde{\eta}_1 \}.$$  

(7.8)

Now we can apply lemma 6.1 for the summation over the partitions $\tilde{u}^c \Rightarrow \{ \tilde{u}_n^c, \tilde{u}_n^c \}$ and $\tilde{v}^c \Rightarrow \{ \tilde{v}_1^c, \tilde{v}_1^c \}$

$$\sum K^{(r)}_k(\tilde{u}_n^c|\tilde{\eta} q^2)K^{(l)}_n(\tilde{u}_n^a|\tilde{u}_n^a)K^{(l)}_n(\{ \tilde{\eta}, \tilde{w}_1 \}|\tilde{u}^c),$$

(7.9)

$$\sum K^{(l)}_n(\tilde{v}_1^c|\tilde{\eta})K^{(r)}_n(\tilde{\eta}|\tilde{v}_1^c q^2)K^{(l)}_n(\{ \tilde{\eta}_n, \tilde{\eta}_1 \}|\tilde{v}^c),$$

(7.10)

where we used (2.6). Then we arrive at

$$S_{a,b}(\tilde{u}^c; \tilde{v}^c|\tilde{u}^a; \tilde{v}^a) = \sum (-q)^{(k-n)}\left( \frac{k_2}{k_1} \right)^{a-k} r_1(\tilde{u}_n^a)r_3(\tilde{v}_1^c)f(\tilde{w}_1, \tilde{\eta})f(\tilde{\eta}, \tilde{w}_n)$$

$$\times f(\tilde{w}_1, \tilde{w}_n)K^{(r)}_k(\tilde{\eta}|\tilde{\eta} q^2)K^{(l)}_n(\tilde{w}_n|\tilde{w}_n)K^{(l)}_n(\{ \tilde{\eta}_n, \tilde{\eta}_1 \}|\tilde{v}^c).$$

(7.11)

7.1. Summation of sub-partitions

In order to make the next step in the summation over the partitions we should specify the subsets of $\tilde{w}$ and $\tilde{\eta}$. For this we introduce new sub-subsets as follows:

$$\tilde{\eta}_n \Rightarrow \{ \tilde{u}_n^a q^{-2}, \tilde{v}_n^a \}, \quad \tilde{u}_n^a \Rightarrow \{ \tilde{u}_n^a, \tilde{\eta}_n^a \},$$

$$\tilde{u}_1 \Rightarrow \{ \tilde{u}_1^c, \tilde{v}_1^c \}, \quad \tilde{v}_1^c \Rightarrow \{ \tilde{v}_1^c, \tilde{u}_1^c \},$$

$$\tilde{\eta}_1 \Rightarrow \{ \tilde{u}_1^a, \tilde{\eta}_1^a \}, \quad \tilde{v}_1^a \Rightarrow \{ \tilde{v}_1^a, \tilde{\eta}_1^a \}. $$

(7.12)

The cardinalities of the sub-subsets above are $\# \tilde{u}_n^a = k_j$ and $\# \tilde{v}_1^a = n_j$. Evidently $\sum_{j=1}^g k_j = a$, $\sum_{j=1}^g n_j = b$ and one can easily see that

$$n_i + n_{ii} = a, \quad k_i + k_{ii} = b,$$

(7.13)

doi:10.1088/1742-5468/2015/03/P03019
Scalar products in $GL(3)$-based models with trigonometric $R$-matrix. Determinant representation

**Remark.** Note that some relations between the cardinalities of the sub-subsets are implicitly shown by the subscripts of the Izergin determinants. For instance, equation (7.11) contains the Izergin determinant $\mathbf{K}_n^k(v_i^c|\bar{u}_i^c q^2)$. This means that $\# v_i^c = \# \bar{u}_i = n$. Using the fact that $v_i^c = \{v_i^c, \bar{v}_i^c\}$ and $\bar{u}_i = \{\bar{u}_i^a, \bar{u}_i^b\}$ we conclude that $n_{\bar{u}_i^a} + n_{\bar{u}_i^b} = n_{\bar{u}_i^{\bar{u}}} + k_{\bar{u}_i} = n$. From this we find $n_{\bar{u}_i^a} = k_{\bar{u}_i}$.

Using the new sub-subsets we recast (7.11) as follows:

$$S_{a,b} = \sum \left( \frac{k_2}{k_1} \right)^{a-k} (-q)^{2(k_a + k_{\bar{u}_i^{\bar{u}}})} r_1(\bar{u}_i^a) r_1(\bar{u}_i^b) r_3(\bar{v}_i^c) r_3(\bar{v}_i^d)
\times f(\bar{u}_i^a, \bar{u}_i^b) f(\bar{u}_i^a, \bar{v}_i^c) f(\bar{u}_i^a, \bar{v}_i^d) f(\bar{u}_i^b, \bar{v}_i^c) f(\bar{u}_i^b, \bar{v}_i^d) f(v_i^c, \bar{v}_i^c) f(v_i^d, \bar{v}_i^d)
\times f(v_i^c, \bar{v}_i^c) f(v_i^c, \bar{v}_i^d) f(v_i^d, \bar{v}_i^c) f(v_i^d, \bar{v}_i^d) f(\bar{v}_i^c, v_i^c) f(\bar{v}_i^c, v_i^d) f(\bar{v}_i^d, v_i^c) f(\bar{v}_i^d, v_i^d)
\times \mathbf{K}_{a,b}^{(i)}(\{v_i^c, \bar{v}_i^c\}|\{\bar{u}_i^q, v_i^c q^2\}) \mathbf{K}_{b}^{(r)}(\{\bar{u}_i^q, \bar{v}_i^{\bar{u}} q^2\}|\bar{v}_i^{\bar{u}} q^2) .$$

Here we used $f(xq^{-2}, y) = f(x, yq^2) = f^{-1}(y, x)$. The next several steps are relatively simple transformations of (7.14). First of all we combine sub-subsets (7.12) into new groups

$$\{\bar{u}_i^a, \bar{u}_i^b\} = \bar{u}_i^a, \quad \{v_i^c, \bar{v}_i^c\} = \bar{v}_i^c,$n_{\bar{u}_i^a} + n_{\bar{u}_i^b} = n_{\bar{u}_i^{\bar{u}}} + k_{\bar{u}_i} = n$. From this we find $n_{\bar{u}_i^a} = k_{\bar{u}_i}.

and denote $n_{\bar{u}_i} = \# \bar{u}_i = \# \bar{v}_i$. Note that the subsets $\bar{u}_i^a$, $\bar{u}_i^b$, $\bar{v}_i^c$, and $\bar{v}_i^d$ are not the same as in (7.11). We use, however, the same notation, as we are dealing with the sum over the partitions, and therefore it does not matter how we denote the separate terms of this sum.

The sum in (7.14) takes the form

$$S_{a,b} = \sum \left( \frac{k_2}{k_1} \right)^{a-k} (-q)^{2(k_a + k_{\bar{u}_i^{\bar{u}}})} r_1(\bar{u}_i^a) r_1(\bar{u}_i^b) r_3(\bar{v}_i^c) r_3(\bar{v}_i^d)
\times f(\bar{u}_i^a, \bar{u}_i^b) f(\bar{u}_i^a, \bar{u}_i^c) f(\bar{u}_i^a, \bar{u}_i^d) f(\bar{u}_i^b, \bar{v}_i^c) f(\bar{u}_i^b, \bar{v}_i^d) f(v_i^c, \bar{v}_i^c) f(v_i^d, \bar{v}_i^d)
\times f(v_i^c, \bar{v}_i^c) f(v_i^c, \bar{v}_i^d) f(v_i^d, \bar{v}_i^c) f(v_i^d, \bar{v}_i^d) f(\bar{v}_i^c, v_i^c) f(\bar{v}_i^c, v_i^d) f(\bar{v}_i^d, v_i^c) f(\bar{v}_i^d, v_i^d)
\times \mathbf{K}_{a,b}^{(r)}(\{v_i^c, \bar{v}_i^c\}|\{\bar{u}_i^q, v_i^c q^2\}) \mathbf{K}_{b}^{(r)}(\{\bar{u}_i^q, \bar{v}_i^{\bar{u}} q^2\}|\bar{v}_i^{\bar{u}} q^2) .$$

Simplifying the Izergin determinants $\mathbf{K}_{a,b}^{(r)}$ and $\mathbf{K}_{b}^{(r)}$ via (6.3) and (6.5) we have

$$\mathbf{K}_{a,b}^{(r)}(\{v_i^c, \bar{v}_i^c\}|\{\bar{u}_i^q, v_i^c q^2\}) = (-q)^{n_{\bar{u}_i^{\bar{u}}} n_{\bar{v}_i^{\bar{u}}}} f^{-1}(\bar{u}_i^q, \bar{v}_i^{\bar{u}} q^2) \mathbf{K}_{b}^{(r)}(\{\bar{u}_i^q, \bar{v}_i^{\bar{u}} q^2\}|\bar{v}_i^{\bar{u}} q^2) ,$$

and

$$\mathbf{K}_{b}^{(r)}(\{\bar{u}_i^q, \bar{v}_i^{\bar{u}} q^2\}|\bar{v}_i^{\bar{u}} q^2) = (-q)^{-(k_a + k_{\bar{v}_i^{\bar{u}}})} f^{-1}(\bar{v}_i^{\bar{u}} q^2, \bar{u}_i^q) \mathbf{K}_{a,b}^{(r)}(\{v_i^c|\bar{u}_i^q q^2\}) .$$

After substituting these formulas into (7.16) we arrive at

$$S_{a,b} = \sum \left( \frac{k_2}{k_1} \right)^{a-k} (-q)^{2(k_a + k_{\bar{u}_i^{\bar{u}}})} r_1(\bar{u}_i^a) r_1(\bar{u}_i^b) r_3(\bar{v}_i^c) r_3(\bar{v}_i^d)
\times f(\bar{u}_i^a, \bar{u}_i^b) f(\bar{u}_i^a, \bar{u}_i^c) f(\bar{u}_i^a, \bar{u}_i^d) f(\bar{u}_i^b, \bar{v}_i^c) f(\bar{u}_i^b, \bar{v}_i^d) f(v_i^c, \bar{v}_i^c) f(v_i^d, \bar{v}_i^d)
\times f(v_i^c, \bar{v}_i^c) f(v_i^c, \bar{v}_i^d) f(v_i^d, \bar{v}_i^c) f(v_i^d, \bar{v}_i^d) f(\bar{v}_i^c, v_i^c) f(\bar{v}_i^c, v_i^d) f(\bar{v}_i^d, v_i^c) f(\bar{v}_i^d, v_i^d)
\times \mathbf{K}_{a,b}^{(r)}(\{v_i^c, \bar{v}_i^c\}|\{\bar{u}_i^q, v_i^c q^2\}) \mathbf{K}_{b}^{(r)}(\{\bar{u}_i^q, \bar{v}_i^{\bar{u}} q^2\}|\bar{v}_i^{\bar{u}} q^2) .$$

This completes the proof of Theorem 7.1.
Scalar products in GL(3)-based models with trigonometric $R$-matrix. Determinant representation

\[
\times \frac{f(\bar{v}_i^g, \bar{u}_i^g) f(\bar{u}_i^g, \bar{u}_i^g) f(\bar{u}_i^g, \bar{c}_i^g) K_{\nu_i}^{(r)}(\bar{v}_i^g | \bar{u}_i^g q^{-2})}{f(\bar{u}_i^g, \bar{u}_i^g) f(\bar{v}_i^g, \bar{u}_i^g)} \times K_{\nu_i}^{(l)} \left( \{ \bar{u}_i^g q^{-2}, \bar{u}_i^g, \bar{c}_i^g \} | \bar{u}_i^g \right) K_{\nu_i}^{(r)} \left( \{ \bar{u}_i^g q^{-2}, \bar{c}_i^g q^{-2} \} | \bar{v}_i^g \right).
\]

(7.19)

The last preliminary step is to introduce two auxiliary functions

\[
\hat{r}_1 (u_i^g) = \frac{r_1 (u_i^g)}{f(u_i^g, \bar{u}_i^g) f(\bar{u}_i^g, \bar{u}_i^g) f(\bar{u}_i^g, \bar{u}_i^g)}, \quad \hat{r}_3 (v_i^g) = \frac{\kappa_2 r_3 (v_i^g) f(v_i^g, \bar{v}_i^g)}{\kappa_3 f(\bar{v}_i^g, v_i^g)}.
\]

(7.20)

Observe that if $u_i^g$ satisfies Bethe equations (3.1) and $v_i^g$ satisfies twisted Bethe equations (4.2), then $\hat{r}_1 (u_i^g) = \hat{r}_3 (v_i^g) = 1$. However, we do not use this fact, treating up to some stage the sets $\bar{u}_i^g$ and $\bar{c}_i^g$ as generic complex numbers. The reason for this will be very clear soon.

Then one can write the products $r_1 (u_i^g)$ and $r_3 (v_i^g)$ as follows:

\[
\begin{aligned}
\hat{r}_1 (u_i^g) &= \hat{r}_1 (u_i^g) \frac{f(\bar{u}_i^g, \bar{u}_i^g) f(\bar{u}_i^g, \bar{u}_i^g)}{f(\bar{u}_i^g, \bar{u}_i^g) f(\bar{u}_i^g, \bar{u}_i^g)} f(\bar{v}_i^g, \bar{u}_i^g), \\
\hat{r}_3 (v_i^g) &= \hat{r}_3 (v_i^g) \frac{\kappa_2 \kappa_3 (v_i^g) f(v_i^g, \bar{v}_i^g)}{\kappa_3 f(\bar{v}_i^g, v_i^g)} f(\bar{v}_i^g, \bar{v}_i^g).
\end{aligned}
\]

(7.21)

(7.22)

Substituting (7.21) and (7.22) into (7.19) we obtain

\[
S_{a,b} = \sum \left( \frac{\kappa_2}{\kappa_3} \right)^{a-k_1} \left( \frac{\kappa_1}{\kappa_3} \right)^{n_i} (-q)^{k_i+k_{ii}-n_{ii}-n_{iv}} f(\bar{u}_i^g, \bar{u}_i^g) f(v_i^g, \bar{v}_i^g)
\]

\[
\times \hat{r}_1 (u_i^g) \hat{r}_3 (v_i^g) f(\bar{u}_i^g, \bar{u}_i^g) f(\bar{v}_i^g, \bar{v}_i^g) \hat{K}_{\nu_i}^{(l)} (\bar{u}_i^g, \bar{u}_i^g) \hat{K}_{\nu_i}^{(r)} (\bar{v}_i^g | \bar{u}_i^g q^{-2}) f(\bar{v}_i^g, \bar{u}_i^g)
\]

\[
\times \hat{K}_{\nu_i}^{(l)} (\{ \bar{u}_i^g q^{-2}, \bar{v}_i^g, \bar{c}_i^g \}) \hat{r}_1 (u_i^g) f(\bar{u}_i^g, \bar{u}_i^g) f(\bar{v}_i^g, \bar{v}_i^g)
\]

\[
\hat{K}_{\nu_i}^{(l)} (\{ \bar{u}_i^g q^{-2}, \bar{u}_i^g, \bar{c}_i^g \}) \hat{r}_3 (v_i^g) f(\bar{v}_i^g, \bar{v}_i^g).
\]

(7.23)

Our goal is to take the sum over partitions $\bar{u}_i^g \Rightarrow \{ \bar{u}_i^g, \bar{u}_i^g \}$ and $\bar{v}_i^g \Rightarrow \{ \bar{v}_i^g, \bar{v}_i^g \}$ via lemma 6.2. For this purpose we present the ratio $f(\bar{v}_i^g, \bar{v}_i^g) / f(\bar{v}_i^g, \bar{v}_i^g)$ in the following form:

\[
\frac{f(\bar{v}_i^g, \bar{v}_i^g)}{f(\bar{v}_i^g, \bar{v}_i^g)} = \frac{f(\bar{v}_i^g, \bar{v}_i^g)}{f(\bar{v}_i^g, \bar{v}_i^g)} = f(\bar{v}_i^g, \bar{v}_i^g) f(\bar{v}_i^g, \bar{v}_i^g).
\]

(7.24)

Then (7.23) turns into

\[
S_{a,b} = \sum \left( \frac{\kappa_1}{\kappa_3} \right)^{n_i} (-q)^{k_i+k_{ii}-n_{ii}-n_{iv}} f(\bar{u}_i^g, \bar{u}_i^g) f(\bar{v}_i^g, \bar{v}_i^g)
\]

\[
\times \hat{r}_1 (u_i^g) \hat{r}_3 (v_i^g) f(\bar{u}_i^g, \bar{u}_i^g) f(\bar{v}_i^g, \bar{v}_i^g) \hat{K}_{\nu_i}^{(l)} (\bar{u}_i^g, \bar{u}_i^g) \hat{K}_{\nu_i}^{(r)} (\bar{v}_i^g | \bar{u}_i^g q^{-2})
\]

\[
\times \hat{K}_{\nu_i}^{(l)} (\{ \bar{u}_i^g q^{-2}, \bar{v}_i^g q^{-2}, \bar{v}_i^g \}) \hat{r}_1 (u_i^g) f(\bar{u}_i^g, \bar{u}_i^g) f(\bar{v}_i^g, \bar{v}_i^g)
\]

\[
\times \hat{K}_{\nu_i}^{(l)} (\{ \bar{u}_i^g q^{-2}, \bar{u}_i^g, \bar{c}_i^g \}) \hat{r}_3 (v_i^g) f(\bar{v}_i^g, \bar{v}_i^g).
\]

(7.25)

where we have used $k_i = n_i$.

The sum over partitions $\bar{u}_i^g \Rightarrow \{ \bar{u}_i^g, \bar{u}_i^g \}$ is only in the last line of (7.25). We can apply lemma 6.2 to this sum if we set

\[
\phi_1 (\gamma) = -q \frac{r_1 (\gamma)}{f(\bar{v}_i^g, \bar{v}_i^g)}, \quad \phi_2 (\gamma) = \frac{\kappa_2}{\kappa_1}.
\]

(7.26)

doi:10.1088/1742-5468/2015/03/P03019
Consider the application of lemma 6.2 in more detail. Denote the sum over the partitions \( \bar{u}_n^B \Rightarrow \{ \bar{u}_n^B, \bar{u}_m^B \} \) in the last line of (7.25) by \( U \):

\[
U = \sum_{\bar{u}_n^B \Rightarrow \{ \bar{u}_n^B, \bar{u}_m^B \}} K_a^{(l)}(\{ \bar{u}_n^B q^{-2}, \bar{u}_m^B, \bar{v}_c^C | \bar{v}_c^C \}) \frac{(-q)^k r_1(\bar{u}_n^B)}{f(\bar{v}_c^C, \bar{u}_m^B)} \left( \frac{\kappa_2}{\kappa_1} \right)^{a-k_i} f(\bar{u}_m^B, \bar{u}_n^B) f(\bar{u}_m^C, \bar{u}_n^C) f(\bar{v}_c^C, \bar{u}_m^B).
\]

(7.27)

Let us also write (6.7) with the functions \( \phi_1 \) and \( \phi_2 \) as in (7.26) and \( m = a \)

\[
p(\bar{\gamma}) L_a(\bar{\gamma} | \bar{\xi}) = \sum_{\bar{\gamma} \Rightarrow \{ \bar{\gamma}_i, \bar{\gamma}_m \}} K_a^{(l)}(\{ \bar{\gamma}_i q^{-2}, \bar{\gamma}_m | \bar{\xi} \}) (-q)^{m_i} \left( \frac{\kappa_2}{\kappa_1} \right)^{m_i} \frac{r_1(\bar{\gamma}_i)}{f(\bar{v}_c^C, \bar{\gamma}_m)} f(\bar{\xi}, \bar{\gamma}_i) f(\bar{\gamma}_m, \bar{\gamma}_i),
\]

(7.28)

where \( m_i = \# \bar{\gamma}_i, \) \( m_m = \# \bar{\gamma}_m, \) and

\[
L_a(\bar{\gamma} | \bar{\xi}) = \Delta_a(\bar{\xi}) \Delta_a(\bar{\gamma}) \det_a [N^{(a)}(\xi_j, \gamma_k) h(\gamma_k, \bar{u}_n^a)],
\]

(7.29)

with \( N^{(a)}(\xi_j, \gamma_k) \) defined in (5.3).

Let now \( \bar{\gamma} = \{ \bar{u}_n^B, \bar{v}_c^C \}. \) Observe that \( \phi_1(\nu_c^B) = 0 \) due to (7.26). Therefore, if \( \bar{v}_c^C \cap \gamma_i \neq \emptyset \), then the corresponding contribution to (7.28) vanishes. Hence, all the non-vanishing contributions to the sum (7.28) correspond only to such partitions for which \( \bar{v}_c^C \subset \gamma_m. \) Therefore, we can set \( \gamma_i = \bar{u}_m^B \) and \( \gamma_m = \{ \bar{u}_m^B, \bar{v}_c^C \}. \) Then \( m_i = k_i, \) \( m_m = a - k_i, \) and (7.28) turns into

\[
p(\bar{u}_n^B) p(\bar{v}_c^C) L_a(\{ \bar{u}_n^B, \bar{v}_c^C | \bar{\xi} \}) = \sum_{\bar{u}_n^B \Rightarrow \{ \bar{u}_n^B, \bar{u}_m^B \}} K_a^{(l)}(\{ \bar{u}_n^B q^{-2}, \bar{u}_m^B, \bar{v}_c^C | \bar{\xi} \})
\]

\[
\times \frac{(-q)^{k_i} r_1(\bar{u}_n^B)}{f(\bar{v}_c^C, \bar{u}_m^B)} \left( \frac{\kappa_2}{\kappa_1} \right)^{a-k_i} f(\bar{u}_m^B, \bar{u}_n^B) f(\bar{\xi}, \bar{u}_m^B) f(\bar{v}_c^C, \bar{u}_n^B).
\]

(7.30)

It remains to set \( \bar{\xi} = \bar{v}_c^C, \) and we reproduce (7.27). Thus, \( U = p(\bar{u}_n^B) p(\bar{v}_c^C) L_a(\{ \bar{u}_n^B, \bar{v}_c^C | \bar{v}_c^C \}). \)

Similarly, the sum over partitions \( \bar{v}_c^C \Rightarrow \{ \bar{v}_c^C, \bar{v}_m^B \} \) is only in the third line of (7.25). We can apply again lemma 6.2 to this sum with the following identifications:

\[
\phi_1(\gamma) = -q^{-1}, \quad \phi_2(\gamma) = \frac{r_3(\gamma)}{f(\gamma, \bar{u}_n^B)}.
\]

(7.31)

Thus, we obtain

\[
S_{a,b} = \sum f(\bar{v}_n^B, \bar{u}_n^B) f(\bar{u}_n^B, \bar{v}_n^B) f(\bar{v}_n^C, \bar{v}_c^C) p(\bar{v}_n^B) p(\bar{v}_c^C)
\]

\[
\times G_{m_1}^{(\kappa)}(\bar{u}_n^B, \bar{v}_c^C) L_a(\{ \bar{u}_n^B, \bar{v}_c^C | \bar{v}_c^C \}) M_b(\{ \bar{u}_n^B, \bar{v}_c^C | \bar{v}_c^C \}),
\]

(7.32)

where

\[
M_b(\bar{v}_m^B) = \Delta_b(\bar{v}_m^B) \Delta_b(\bar{\gamma}) \det_b [N^{(b)}(\nu_j^B, \gamma_k) h(\gamma_k, \bar{v}_m^B)],
\]

(7.33)

with \( N^{(b)}(\nu_j^B, \gamma_k) \) defined in (5.4).

The function \( G_{m_1}^{(\kappa)} \) is still given as the sum over the partitions \( \bar{u}_n^B \Rightarrow \{ \bar{u}_n^B, \bar{u}_m^B \} \) and \( \bar{v}_c^C \Rightarrow \{ \bar{v}_c^C, \bar{v}_i^C \}:

\[
G_{m_1}^{(\kappa)}(\bar{u}_n^B, \bar{v}_c^C) = \sum \left( \frac{\kappa_1}{\kappa_3} \right)^{m_i} q^{m_i} r_1(\bar{u}_n^B) r_3(\bar{v}_c^C) f(\bar{u}_m^B, \bar{v}_m^B) f(\bar{v}_c^C, \bar{v}_i^C) K_{m_1}^{(l)}(\bar{u}_m^B | \bar{v}_i^C) K_{m_1}^{(r)}(\bar{v}_i^C | \bar{u}_n^B q^{-2}).
\]

(7.34)

It is important that up to now we did not use (twisted) Bethe equations for the parameters \( \bar{v}_c^C \) and \( \bar{u}_n^B. \) In all the above calculations we considered these parameters as generic complex

\[\text{doi:10.1088/1742-5468/2015/03/P03019}\]
numbers. Therefore, the matrix elements \( N^{(v)}(u^C_j, u^B_k) \) (5.3) and \( N^{(v)}(v^B_j, v^C_k) \) (5.4) are well defined even in the case when \( \tilde{u}^C \cap \tilde{u}^B \neq \emptyset \) or \( \tilde{v}^C \cap \tilde{v}^B \neq \emptyset \). Indeed, since we have no restriction for \( \tilde{v}^C \) and \( \tilde{u}^B \), it is no problem to take the limits \( u^B_k \to u^C_j \) in (5.3) or \( v^B_j \to v^C_k \) in (5.4). Therefore, if some of the Bethe parameters from different Bethe vectors coincide, then the corresponding matrix elements \( N^{(v)}(u^C_j, u^B_k) \) and \( N^{(v)}(v^B_j, v^C_k) \) should be understood as in (5.11) and (5.12).

8. Final summations

After we have defined the matrices \( N^{(v)} \) and \( N^{(v)} \) for all possible values of the Bethe parameters, we can impose (twisted) Bethe equations for the sets \( \tilde{v}^C \) and \( \tilde{u}^B \). Then we have particular cases, namely \( \kappa \). Consider these two cases separately.

It convenient to present all the functions \( G^{(v)}(u^B_i, \tilde{u}^B_i) \) and \( G^{(v)}(v^C_j, \tilde{v}^C_j) \) as

\[
G^{(v)}(u^B_i, \tilde{u}^B_i) = \sum \left( \frac{\kappa_1}{\kappa_2} \right)^n q^{2n} f(u^B_i, \tilde{u}^B_i) f(\tilde{v}^C_i, \tilde{u}^B_i) \mathcal{K}^{(v)}(u^B_i, \tilde{u}^B_i) \mathcal{K}^{(v)}(\tilde{v}^C_i, \tilde{u}^B_i) q^{-2}.
\]

(8.1)

We cannot calculate this sum at generic \( \kappa_1/\kappa_3 \). However, we know the result for \( G^{(v)} \) in two particular cases, namely \( \kappa_3/\kappa_1 = 1 \) and \( \kappa_3/\kappa_1 = q^2 \). They are described by corollaries 6.1 and 6.2. Let us denote the corresponding functions \( G^{(v)}(u^B_i, \tilde{u}^B_i) \) by \( G^{(v)} \) and \( G^{(v)} \), respectively. Then we have

\[
G^{(v)} = (-1)^n q^{-n} t(\tilde{v}^C_i, u^B_i) h(\tilde{v}^C_i, v^B_i) h(\tilde{v}^C_i, v^B_i),
\]

(8.2)

and

\[
G^{(v)} = (-1)^n t(\tilde{v}^C_i, v^B_i) h(\tilde{v}^C_i, v^B_i) h(\tilde{v}^C_i, v^B_i).
\]

(8.3)

Consider these two cases separately.

8.1. The case \( \kappa_3/\kappa_1 = 1 \)

Without loss of generality we can set \( \kappa_1 = \kappa_3 = 1 \). Let us denote the corresponding scalar product by \( S^{(b)} \). Substituting (8.2) into (7.32) we obtain

\[
S^{(b)} = p(\tilde{v}^C_i) p(u^B_i) \sum (-1)^n f(\tilde{v}^C_i, u^B_i) f(u^B_i, \tilde{v}^C_i) t(\tilde{v}^C_i, v^B_i) h(\tilde{v}^C_i, v^B_i) h(\tilde{v}^C_i, v^B_i)
\times L_a(\{u^B_i, \tilde{v}^C_i\} | \tilde{v}^C_i) M_b(\{u^B_i, \tilde{v}^C_i\} | \tilde{v}^C_i).
\]

(8.4)

Now we introduce

\[
\hat{L}_a(\gamma | \tilde{v}^C_i) = L_a(\gamma | \tilde{v}^C_i) h(\gamma, \tilde{v}^C_i), \quad \hat{M}_b(\gamma | \tilde{v}^C_i) = M_b(\gamma | \tilde{v}^C_i) h(\gamma, \tilde{v}^C_i),
\]

(8.5)

and then the equation (8.4) takes the form

\[
S^{(b)} = p(\tilde{v}^C_i) p(u^B_i) \sum (-1)^n f(\tilde{v}^C_i, u^B_i) f(u^B_i, \tilde{v}^C_i) t(\tilde{v}^C_i, v^B_i) h(\tilde{v}^C_i, v^B_i) h(\tilde{v}^C_i, v^B_i)
\times h(u^B_i, \tilde{v}^C_i) h(\tilde{v}^C_i, u^B_i) h(\tilde{v}^C_i, u^B_i) \hat{L}_a(\{u^B_i, \tilde{v}^C_i\} | \tilde{v}^C_i) \hat{M}_b(\{u^B_i, \tilde{v}^C_i\} | \tilde{v}^C_i).
\]

(8.6)

It convenient to present all the functions \( f(x, y) \) as \( f(x, y) = g(x, y) h(x, y) \), all the functions \( t(x, y) \) as \( t(x, y) = g(x, y) / h(x, y) \), and then to combine separately all the functions \( h(x, y) \) and all the functions \( g(x, y) \). We obtain

\[
S^{(b)} = p(\tilde{v}^C_i) p(u^B_i) C_h \sum g(\tilde{v}^C_i, u^B_i) g(u^B_i, \tilde{v}^C_i) g(\tilde{v}^C_i, u^B_i) g(\tilde{v}^C_i, \tilde{v}^C_i)
\times \hat{L}_a(\{u^B_i, \tilde{v}^C_i\} | \tilde{v}^C_i) \hat{M}_b(\{u^B_i, \tilde{v}^C_i\} | \tilde{v}^C_i).
\]

(8.7)

doi:10.1088/1742-5468/2015/03/P03019 17
where $C_n$ is given by (5.2). Recall also that
\[
\hat{L}_a(\bar{\gamma}|\bar{u}^C) = \Delta_a'(\bar{u}^C)\Delta_a(\bar{\gamma}) \det_a N^{(u)}(u^C, \gamma_k), \quad \hat{M}_b(\bar{\gamma}|\bar{u}^B) = \Delta'_b(\bar{u}^B)\Delta_b(\bar{\gamma}) \det_b N^{(v)}(v^B, \gamma_k),
\]
(8.8)
and the matrices $N^{(u)}(u^C, \gamma_k), N^{(v)}(v^B, \gamma_k)$ are given by (5.3) and (5.4). It remains to apply the following

**Proposition 8.1.** Let $N$ be an $(a+b) \times (a+b)$ matrix and $\bar{x} = \{x_1, \ldots, x_{a+b}\}$ be a set of variables. Let the matrix elements of $N$ have the form
\[
N_{jk} = N^{(1)}_j(x_k), \quad j = 1, \ldots, a
\]
\[
N_{jk} = N^{(2)}_j(x_k), \quad j = a+1, \ldots, a+b,
\]
where $N^{(1)}_j(x)$ and $N^{(2)}_j(x)$ are some functions of $x$. Then
\[
\Delta_{a+b}(\bar{x}) \det N = \sum g(\bar{x}_B, \bar{x}_I) \left[ \Delta_a(\bar{x}_I) \det_a (N^{(1)}_j(x_k)) \right] \cdot \left[ \Delta_b(\bar{x}_B) \det_b (N^{(2)}_j(x_k)) \right].
\]
(8.10)
Here the sum is taken with respect to the partitions $\bar{x} \Rightarrow \{\bar{x}_I, \bar{x}_B\}$ with $\#\bar{x}_I = a$ and $\#\bar{x}_B = b$. The notation $x_k$ (resp. $x_k'$) means the $k$-th element of the subset $x_i$ (resp. $x_i'$), and we assume that the elements in every subset are ordered in the natural order.

**Proof.** Developing $\det_{a+b} N$ with respect to the first $a$ rows we obtain
\[
\det_{a+b} N = \sum (-1)^{|P|} \det_a (N^{(1)}_j(x_k)) \cdot \det_b (N^{(2)}_j(x_k)),
\]
(8.11)
where the sum is taken with respect to the partitions $\bar{x} \Rightarrow \{\bar{x}_I, \bar{x}_B\}$ with $\#\bar{x}_I = a$ and $\#\bar{x}_B = b$. The symbol $|P|$ means the parity of the permutation $P_{a+b}$ mapping the union of the subsets $\{\bar{x}_I, \bar{x}_B\}$ into the naturally ordered set $\bar{x}$. On the other hand the product $(\Delta(\bar{x}))^{-1}$ coincides up to a constant with the Vandermonde determinant of variables $\bar{x}$. Reordering the rows of this determinant by the permutation $P_{a+b}^{-1}$ we obtain
\[
\Delta_{a+b}(\bar{x}) = (-1)^{|P|} g(\bar{x}_B, \bar{x}_I) \Delta_a(\bar{x}_I) \Delta_b(\bar{x}_B),
\]
(8.12)
and hence,
\[
(-1)^{|P|} = g(\bar{x}_B, \bar{x}_I) \Delta_a(\bar{x}_I) \Delta_b(\bar{x}_B)
\]
(8.13)
for the arbitrary partition $\bar{x} \Rightarrow \{\bar{x}_I, \bar{x}_B\}$. Substituting (8.13) into (8.11) we immediately arrive at (8.10).

It is easy to see that (8.7) is a particular case of (8.10). Indeed, define a set $\bar{x}$ as in (5.5)
\[
\bar{x} = \{\bar{u}^u, \bar{v}^C\} = \{u_1^u, \ldots, u_a^u, v_1^C, \ldots, v_b^C\},
\]
(8.14)
and let us set in (8.9)
\[
N^{(1)}_j(x) = N^{(u)}(u^C, x), \quad N^{(2)}_j(x) = N^{(v)}(v^B, x).
\]
(8.15)
Then due to proposition 8.1
\[
\Delta_a'(\bar{u}^C)\Delta'_b(\bar{v}^B)\Delta_{a+b}(\bar{x}) \det N
\]
\[
= \sum g(\bar{x}_B, \bar{x}_I) \left[ \Delta'_a(\bar{u}^C)\Delta_a(\bar{x}_I) \det_a (N^{(u)}(u^C, x_k)) \right] \cdot \left[ \Delta'_b(\bar{v}^B)\Delta_b(\bar{x}_B) \det_b (N^{(v)}(v^B, x_k)) \right]
\]
\[
= \sum g(\bar{x}_B, \bar{x}_I) \hat{L}_a(\bar{x}_I|\bar{u}^C) \hat{M}_b(\bar{x}_B|\bar{v}^B).
\]
(8.16)
If we set $\bar{x}_I = \{\bar{u}^u, \bar{v}'_i\}$ and $\bar{x}_B = \{\bar{u}'_i, \bar{v}^C\}$, then we reproduce the sum in the rhs (8.7). Thus, we finally obtain the result (5.6).
8.2. The case $κ_3/κ_1 = q^2$

Consider now the case $κ_3/κ_1 = q^2$. Let us denote the corresponding scalar product by $S_{a,b}^{(q^2)}$. Substituting (8.3) into (7.32) we obtain

$$S_{a,b}^{(q^2)} = p(v_{a})\sum_{(i)}(-1)^{i}f(\tilde{e}_{a}^{C\alpha},\tilde{e}_{a}^{\alpha})f(\tilde{v}_{a}^{C\alpha},\tilde{v}_{a}^{\alpha})f(\tilde{v}_{a}^{C\beta},\tilde{v}_{a}^{\beta})t(\tilde{e}_{a}^{C\alpha},\tilde{v}_{a}^{\alpha})h(\tilde{e}_{a}^{\alpha},\tilde{v}_{a}^{\alpha})h(\tilde{e}_{a}^{\alpha},\tilde{v}_{a}^{\alpha})$$

Acting exactly in the same manner as before we obtain

$$S_{a,b}^{(q^2)} = p(v_{a})C_{b}\sum_{(i)}g(\tilde{e}_{a}^{C\alpha},\tilde{e}_{a}^{\alpha})g(\tilde{e}_{a}^{C\beta},\tilde{e}_{a}^{\beta})g(\tilde{v}_{a}^{C\alpha},\tilde{v}_{a}^{\alpha})g(\tilde{v}_{a}^{C\beta},\tilde{v}_{a}^{\beta})$$

Comparing the obtained equation with (8.7) we see that the difference is very small, namely, we have the additional factor $p(\tilde{v}_{a}^{C\alpha})p(\tilde{v}_{a}^{C\beta})$ in (8.17). This factor can be easily included into the determinants. Consider the matrix $N(\tilde{x})$. Then due to proposition 8.1 we have

$$\Delta_{\tilde{a}}(\tilde{v}^{\alpha})\Delta_{\tilde{b}}(\tilde{v}^{\beta})\Delta_{\tilde{c}}(\tilde{v}^{\gamma}) \text{ det} N(\tilde{x}) = \sum_{a, b} g(\tilde{x}_{a}, \tilde{x}_{b}) \left[ \Delta_{\tilde{a}}(\tilde{v}^{\alpha})\Delta_{\tilde{a}}(\tilde{x}_{a}) \text{ det}(N^{(u)}(u_{j}^{a}, x_{k}^{a})) \right]$$

$$\times \left[ \Delta_{\tilde{b}}(\tilde{v}^{\beta})\Delta_{\tilde{b}}(\tilde{x}_{b}) \text{ det}(N^{(v)}(v_{j}^{b}, x_{k}^{b})) \right]$$

$$= \sum_{a, b} g(\tilde{x}_{a}, \tilde{x}_{b}) \left[ \Delta_{\tilde{a}}(\tilde{v}^{\alpha})\Delta_{\tilde{a}}(\tilde{x}_{a}) \text{ det}(N^{(u)}(u_{j}^{a}, x_{k}^{a})) \right]$$

$$\times \left[ \Delta_{\tilde{b}}(\tilde{v}^{\beta})\Delta_{\tilde{b}}(\tilde{x}_{b}) \text{ det}(N^{(v)}(v_{j}^{b}, x_{k}^{b})) \right]$$

$$= \sum_{a, b} g(\tilde{x}_{a}, \tilde{x}_{b}) \left[ \Delta_{\tilde{a}}(\tilde{v}^{\alpha})\Delta_{\tilde{a}}(\tilde{x}_{a}) \text{ det}(N^{(u)}(u_{j}^{a}, x_{k}^{a})) \right]$$

$$\times \left[ \Delta_{\tilde{b}}(\tilde{v}^{\beta})\Delta_{\tilde{b}}(\tilde{x}_{b}) \text{ det}(N^{(v)}(v_{j}^{b}, x_{k}^{b})) \right]$$

After specification $\tilde{x}_{a} = \{\tilde{u}_{a}^{\alpha}, \tilde{v}_{a}^{\alpha}\}$ and $\tilde{x}_{b} = \{\tilde{u}_{b}^{\alpha}, \tilde{v}_{b}^{\alpha}\}$ we reproduce the sum in the rhs of (8.17). Thus, we finally arrive at (5.10).

9. Discussions

We have described the derivation of the determinant formulas for the scalar product of twisted and usual on-shell Bethe vectors in the generalized $GL(3)$-based model with the trigonometric $R$-matrix. Comparing this derivation with the one given in [9, 10] for the case of the $GL(3)$-invariant $R$-matrix we see that not only the general line, but even the details are almost the same. The differences are very small and mostly occur in the presence of degrees of the deformation parameter $q$. However, these negligible differences eventually lead to drastic consequences. Namely, we succeeded in obtaining the determinant representation for the form factor of the operator $T_{22}(z)$ only. The other two form factors of the diagonal entries are unattainable within the framework of our scheme. Indeed, in order to calculate the form factors of $T_{11}(z)$ and $T_{33}(z)$ we should be able to compute $κ$-derivatives of the function $G^{(κ)}_{a,b}(8.1)$ at $κ = 1$

$$\frac{dG^{(κ)}_{a,b}}{dκ} \bigg|_{κ = 1} = \pm \sum_{n} n_{i} q^{2n}f(\tilde{u}_{a}^{\alpha}, \tilde{v}_{a}^{\alpha})f(\tilde{v}_{a}^{C\alpha}, \tilde{v}_{a}^{\alpha})K_{n_{i}}^{(l)}(\tilde{u}_{b}^{\alpha}, \tilde{v}_{b}^{\alpha}) K_{n_{i}}^{(r)}(\tilde{v}_{b}^{C\alpha}, \tilde{u}_{b}^{\alpha})$$

$$q^{-2}, \quad (9.1)$$

where $s = 1, 3$. In the case of the $GL(3)$-invariant $R$-matrix an analog of this sum over the partitions was calculated in [10]. However, in the $q$-deformed case the sum (9.1) is not described by summation lemma 6.3 or its corollaries. In particular, we have the $q$-number $[n_{i}]$ in the identity (6.15), while (9.1) contains the usual number $n_{i}$.

doi:10.1088/1742-5468/2015/03/P03019
Curiously, for the other matrix elements \( T_{ij}(z) \) we have a similar situation: we cannot obtain a determinant representation for the usual form factors; however, it can be done for twisted form factors if the twist parameters are related to the deformation parameter \( q \). In particular, we have found a determinant representation for the twisted form factor of the operator \( T_{12}(z) \), provided \( \kappa_3/\kappa_1 = q \) and \( \kappa_2 \) is arbitrary. For completeness we describe this result below; however, we do not give the detailed derivation, because its main steps coincide with the ones of [11], while the peculiarities arising due to the \( q \)-deformation are already described in the present paper.

The twisted form factor of \( T_{12}(z) \) is defined as

\[
\mathcal{F}_{a,b,h}^{(1,2)}(z) \equiv \mathcal{F}_{a,b,h}^{(1,2)}(z|\bar{u}^C, \bar{v}^C; \bar{u}^B, \bar{v}^B) = C^{a+1,b}(\bar{u}^C; \bar{v}^C)T_{12}(z)\mathbb{B}^{a,b}(\bar{u}^B; \bar{v}^B),
\]

where \( C^{a+1,b}(\bar{u}^C; \bar{v}^C) \) is a twisted on-shell Bethe vector, while \( \mathbb{B}^{a,b}(\bar{u}^B; \bar{v}^B) \) is a standard on-shell Bethe vector. Note that in the distinction of the case considered above the number of elements in the set \( \bar{u}^C \) is \( a + 1 \).

If \( \kappa_3/\kappa_1 = q \), then a determinant representation for \( \mathcal{F}_{a,b,h}^{(1,2)}(z) \) has the following form:

\[
\mathcal{F}_{a,b,h}^{(1,2)}(z) = z p(\bar{u}^B)p(\bar{u}^B)C_{kh}(\bar{v}^C, z)h(z, \bar{u}^B)\Delta_{a+1}(\bar{u}^C)\Delta_{a+b+1}(\bar{x}) \det N^{(12)}_{a+b+1} \det N^{(12)}_{a+1,k},
\]

where

\[
N^{(a)}_{j,k}(u^C_j, x_k), \quad j = 1, \ldots, a + 1, \\
N^{(b)}_{j+a+1,k}(v^B_j, x_k), \quad j = 1, \ldots, b, \quad \{x_1, \ldots, x_{a+b+1}\} = \{u_1^a, \ldots, u_a^a, z, v_1^b, \ldots, v_b^b\},
\]

(9.3)

The matrix elements \( N^{(a)}(u^C_j, x_k) \) are given by (5.4), and the matrix elements \( N^{(b)}(v^B_j, x_k) \) are given by (5.3), where one should replace \((-1)^{a-1}\) by \((-1)^a\). This replacement is related to the fact that now the set \( \bar{u}^C \) consists of \( a + 1 \) elements.

It is worth mentioning that if we consider twisted form factors where \( C^{a,b}(\bar{u}^C; \bar{v}^C) \) is a usual on-shell Bethe vector, while \( \mathbb{B}^{a,b}(\bar{u}^B; \bar{v}^B) \) is a twisted on-shell Bethe vector, then in order to obtain a determinant representation one should take the inverse ratios of the twist parameters. For example, the determinant representations for these twisted form factors of the operators \( T_{11}(z) \) and \( T_{33}(z) \) exist if \( \kappa_3/\kappa_1 = q^{-2} \). This is not surprising, because one can say that \( T_{11}(u) \) is the original monodromy matrix, and then \( T_{11}(u) \) becomes a twisted monodromy matrix with the twist parameters \( \kappa_1^{-1} \). In other words only the relative twist is important.

This observation makes it impossible to expand over the twisted form factors with the fixed ratios of the twist parameters. Generically twisted form factors can be used for the expansion of complex operators (see, e.g. [17]). For instance, if we need to calculate the matrix element of the product \( T_{11}(z_1)T_{33}(z_2) \), then we can expand it into a form factor series as follows:

\[
C^{a,b}(\bar{u}^C; \bar{v}^C)T_{11}(z_1)T_{33}(z_2)\mathbb{B}^{a,b}(\bar{u}^B; \bar{v}^B)
= \sum_{\{a,v\}} \frac{1}{||\mathbb{B}^{a,v}(\bar{u}; \bar{v})||^2} C^{a,b}(\bar{u}^C; \bar{v}^C)T_{11}(z_1)\mathbb{B}^{a,b}(\bar{u}; \bar{v}) \cdot C^{a,b}(\bar{u}; \bar{v})T_{33}(z_2)\mathbb{B}^{a,b}(\bar{u}^B; \bar{v}^B).
\]

(9.5)

Here the vectors \( \mathbb{B}^{a,b}(\bar{u}; \bar{v}) \) (and their dual \( C^{a,b}(\bar{u}; \bar{v}) \)) are not necessarily usual on-shell Bethe vectors. They might be twisted on-shell Bethe vectors as well. In the last case we are just dealing with the twisted form factors. Suppose that \( C^{a,b}(\bar{u}; \bar{v}) \) in (9.5) is a twisted on-shell dual Bethe vector with \( \kappa_3/\kappa_1 = q^2 \). Then we know the determinant representation

doi:10.1088/1742-5468/2015/03/P03019 20
for this twisted form factor. But in this case the twisted on-shell Bethe vector $\mathbb{B}^{a,b}(\bar{u}; \bar{v})$ also has $\kappa_3/\kappa_1 = q^2$, and hence, we do not know a determinant representation for this twisted form factor. Thus, the determinant representations obtained above cannot be used in (9.5).

In conclusion to this discussion we would like to comment on the zero modes method developed in [13] for calculating the form factors in $GL(3)$-invariant models. There it was proved that the form factors of all matrix elements $T_{ij}(z)$ can be obtained from one initial form factor, say $\mathcal{F}^{(2,2)}_{a,b}(z)$, by taking the special limits of the Bethe parameters. Since in the $q$-deformed case the determinant formula for the form factor $\mathcal{F}^{(2,2)}_{a,b}(z)$ is known, one could hope to apply the same approach in order to derive determinants in the $q$-deformed case for other operators $T_{ij}(z)$. However, the zero modes method fails for the models with the trigonometric $R$-matrix. It is possible that there exists some modification of this method, which makes it applicable to these models. But to date such a modification is not known.

In the light of the foregoing, the existence of the determinant formula for the form factor of $T_{22}(z)$ appears to be a miraculous exception. At the same time this fact allows us to hope that determinant formulas for other form factors also exist and can be obtained by certain improvements to the method described in the present paper.

**Acknowledgments**

It is my great pleasure to thank my colleagues S Pakuliak and E Ragousy for their numerous and fruitful discussions. This work was supported by the RSF under grant 14-50-00005.

**Appendix A. Proof of lemma 6.2**

Consider a partition of a set $\tilde{\gamma}$ into two subsets $\{\tilde{\gamma}_1, \tilde{\gamma}_2\}$ with $\# \tilde{\gamma}_1 = n, n = 0, \ldots, m$. Let us write explicitly the Izergin determinant $K_m^{(l,r)}(\{\tilde{\gamma}_1 q^{-2}, \tilde{\gamma}_2\}|\xi)$:

$$K_m^{(l,r)}(\{\tilde{\gamma}_1 q^{-2}, \tilde{\gamma}_2\}|\xi) = q^{-n} p^{l,r} \Delta_m(\xi) \Delta_n(\tilde{\gamma}_1 q^{-2}) \Delta_{m-n}(\tilde{\gamma}_2) g(\tilde{\gamma}_2, \tilde{\gamma}_1 q^{-2})$$

$$\times \det_m \left( t(\gamma_k^q q^{-2}, \xi_j) \right) .$$

(A.1)

Here the symbols $\gamma_k^q$ (resp. $\gamma_k^u$) denote the $k$-th element of the subset $\gamma_1$ (resp. $\gamma_u$). Recall that the elements in every subset are ordered in the natural order. The matrix elements in the first $n$ columns of the determinant in (A.1) are equal to $t(\gamma_k^q q^{-2}, \xi_j)$, while in the last $(m-n)$ columns we have $t(\gamma_k^u, \xi_j)$. Due to relations (2.6) the equation (A.1) can be written in the form

$$K_m^{(l,r)}(\{\tilde{\gamma}_1 q^{-2}, \tilde{\gamma}_2\}|\xi) = q^{-n} p^{l,r} \Delta_m(\xi) \Delta_n(\tilde{\gamma}_1) \Delta_{m-n}(\tilde{\gamma}_2) g(\tilde{\gamma}_2, \tilde{\gamma}_1) \det_m \left( t(\xi_j, \gamma_k^q) \right) \left( t(\gamma_k^q, \xi_j) \right) .$$

(A.2)

Hence, we obtain

$$K_m^{(l,r)}(\{\tilde{\gamma}_1 q^{-2}, \tilde{\gamma}_2\}|\xi) = p^{l,r} \Delta_m(\xi) \Delta_n(\tilde{\gamma}_1) \Delta_{m-n}(\tilde{\gamma}_2) g(\tilde{\gamma}_2, \tilde{\gamma}_1)$$

$$\times \det_m \left( \left( -1 \right)^m q^{-1} t(\xi_j, \gamma_k^q) \right) \left( t(\gamma_k^q, \xi_j) \right) .$$

Scalar products in GL(3)-based models with trigonometric R-matrix. Determinant representation

Consider now the rhs of (6.7) as a functional of functions \( \phi_1(\gamma) \) and \( \phi_2(\gamma) \). Clearly this functional is linear with respect to any \( \phi_1(\gamma_k) \) and \( \phi_2(\gamma_k) \), \( k = 1, \ldots, m \). Therefore we have

\[
p^{lr} \Delta_m(\bar{\xi}) \Delta_m(\bar{\gamma}) \det_m \left( \phi_2(\gamma_k) t(\gamma_k, \xi_j) h(\gamma_k, \bar{\xi}) + q^{\mp 1} (-1)^m \phi_1(\gamma_k) t(\xi_j, \gamma_k) h(\bar{\xi}, \gamma_k) \right)
\]

\[
= \sum \phi_1(\bar{\gamma}_l) \phi_2(\bar{\gamma}_n) A(\bar{\gamma}_l, \bar{\gamma}_n),
\]

(A.4)

where the sum is taken over all the partitions \( \bar{\gamma} \Rightarrow \{ \bar{\gamma}_l, \bar{\gamma}_n \} \), and the coefficients \( A(\bar{\gamma}_l, \bar{\gamma}_n) \) do not depend on \( \phi_1 \) and \( \phi_2 \). In order to find \( A(\bar{\gamma}_l, \bar{\gamma}_n) \) corresponding to fixed subsets \( \bar{\gamma}_l \) and \( \bar{\gamma}_n \) we should set in the lhs of (A.4)

\[
\phi_1(\gamma_k) = 0, \quad \text{if} \quad \gamma_k \in \bar{\gamma}_n,
\]

\[
\phi_2(\gamma_k) = 0, \quad \text{if} \quad \gamma_k \in \bar{\gamma}_l.
\]

(A.5)

Due to the symmetry of the lhs of (A.4) with respect to all \( \gamma_k \) we can move all the columns corresponding to the elements \( \gamma_k \in \bar{\gamma}_l \) to the left. Simultaneously we should make the same reordering in the product \( \Delta_m(\bar{\gamma}) \). Then we obtain

\[
A(\bar{\gamma}_l, \bar{\gamma}_n) = p^{lr} \Delta_m(\bar{\xi}) \Delta_m(\bar{\gamma}) \Delta_{m-n}(\bar{\gamma}_n) g(\bar{\gamma}_n, \bar{\gamma}_l)
\]

\[
\times \det_m \left( (-1)^m q^{\mp 1} t(\xi_j, \gamma_k' h(\bar{\xi}, \gamma_k') \right) \left( (\gamma_k', \xi_j) h(\bar{\gamma}_n, \bar{\xi}) \right).
\]

(A.6)

Comparing this equation with (A.3) we arrive at the statement of lemma. \( \square \)

Appendix B. Proof of lemma 6.3

The proof is based on induction over \( n \). It is convenient to denote the lhs and the rhs of (6.8) respectively by \( \Lambda_n^{(l)}(\bar{\alpha}|\bar{\beta}) \) and \( \Lambda_n^{(r)}(\bar{\alpha}|\bar{\beta}) \). Then we consider the residues of these rational functions in the poles. The last one occurs in the points \( \alpha_i = \beta_j \) and \( \alpha_i = \beta_i q^{-2} \), \( i, j = 1, \ldots, n \). The goal is to prove that the residues in the above poles can be expressed in terms of \( \Lambda_{n-1}^{(l)}(\bar{\alpha}|\bar{\beta}) \) and \( \Lambda_{n-1}^{(r)}(\bar{\alpha}|\bar{\beta}) \). This will give us the induction step.

First of all, observe that at \( n_l \) and \( n_r \) fixed the sum over the partitions of the set \( \bar{\alpha} \) can be calculated explicitly via lemma 6.1

\[
\sum_{\bar{\alpha} \Rightarrow \{ \bar{\alpha}_l, \bar{\alpha}_n \}} f(\bar{\alpha}_l, \bar{\alpha}_n) K^{(r)}_n(\bar{\beta}_l|\bar{\alpha}_l) K^{(l)}_n(\bar{\alpha}_n|\bar{\beta}_n q^{-2}) = (-q)^{-n_l} f(\bar{\alpha}, \bar{\beta}_n q^{-2}) K^{(r)}_n(\{ \bar{\beta}_n q^{-4}, \bar{\beta}_l \}|\bar{\alpha}).
\]

(B.1)

Thus, the lhs of (6.8) takes the form

\[
\Lambda_n^{(l)}(\bar{\alpha}|\bar{\beta}) = \sum_{\bar{\beta} \Rightarrow \{ \bar{\beta}_l, \bar{\beta}_n \}} (-1)^{n_l} q^{n_l-n_r} f(\bar{\beta}_l, z) f(\bar{\beta}_l, \bar{\beta}_n) f(\bar{\alpha}, \bar{\beta}_n q^{-2}) K^{(r)}_n(\{ \bar{\beta}_n q^{-4}, \bar{\beta}_l \}|\bar{\alpha}).
\]

(B.2)

We will consider \( \Lambda_n^{(l)}(\bar{\alpha}|\bar{\beta}) \) and \( \Lambda_n^{(r)}(\bar{\alpha}|\bar{\beta}) \) as functions of \( \alpha_n \) and other fixed variables. They are rational functions of \( \alpha_n \) and they have poles at \( \alpha_n = \beta_k \) and \( \alpha_n = \beta_k q^{-2} \), \( k = 1, \ldots, n \). Consider the properties of these functions in the mentioned poles. Due to the symmetry of both functions over \( \beta \) it is enough to consider the case \( \beta_k = \beta_n \).

Let \( \alpha_n = \beta_n \). The pole of \( \Lambda_n^{(l)}(\bar{\alpha}|\bar{\beta}) \) occurs if and only if \( \beta_n \in \bar{\beta} \). Let \( \bar{\beta}_l = \{ \beta_n, \bar{\beta}_l \} \). Then setting \( n_r = n_l - 1 \) and using the property of the Izergin determinant (6.4) we get

\[ \text{The poles of the Izergin determinant at } \alpha_n = \beta_k q^{-4} \text{ are compensated by the zeros of the product } f(\hat{\alpha}, \bar{\beta}_n q^{-2}). \]

doi:10.1088/1742-5468/2015/03/P03019
The terms $f(\beta_n, z)$ and $f(\beta_n, \alpha_n) f(\alpha_n, \bar{\alpha}_n)$ can be moved out of the sum. The terms $f(\bar{\beta}_n, \beta_n)$ and $f(\beta_n, \beta_n)$ combine into $f(\bar{\beta}_n, \beta_n)$ and also can be moved out of the sum. Finally, the terms $f(\alpha_n, \bar{\beta}_n q^{-2})$ and $f(\beta_n q^{-4}, \beta_n)$ cancel each other. We obtain

$$
\Lambda^{(l)}_{n-1}(\bar{\alpha}_n | \bar{\beta}_n) = q f(\alpha_n, f(\beta_n, z) f(\bar{\beta}_n, \beta_n) f(\alpha_n, \bar{\alpha}_n) + \text{reg.} \quad (B.4)
$$

The remaining sum evidently gives $\Lambda^{(l)}_{n-1}(\bar{\alpha}_n | \bar{\beta}_n)$, and we arrive at

$$
\Lambda^{(l)}_{n}(\bar{\alpha}_n | \bar{\beta}_n) = q f(\alpha_n, f(\beta_n, z) f(\bar{\beta}_n, \beta_n) f(\alpha_n, \bar{\alpha}_n) + \text{reg.} \quad (B.5)
$$

Let now $\alpha_n = \beta_n q^{-2}$. The pole of $\Lambda^{(l)}_{n}(\bar{\alpha}_n | \bar{\beta}_n)$ occurs if and only if $\beta_n \in \bar{\beta}_n$. Let $\bar{\beta}_n = \{ \beta_n, \bar{\beta}_n \}$. Then setting $n_{\beta'} = n_{\beta} - 1$ and using the property of the Izergin determinant (6.3) we obtain

$$
\Lambda^{(l)}_{n}(\bar{\alpha}_n | \bar{\beta}_n) = q\sum_{\beta \rightarrow \beta' \in \bar{\beta}_n} (\Lambda^{(l)}_{n-1}(\beta_n | \beta_n) + \text{reg.}) \quad (B.6)
$$

The terms $f(\alpha_n, \beta_n q^{-2}) f(\bar{\alpha}_n, \alpha_n) f(\beta_n, \bar{\beta}_n) f(\alpha_n, \bar{\alpha}_n) + \text{reg.}$ (B.7)

The terms $f(\alpha_n, \beta_n q^{-2}) f(\alpha_n, \alpha_n) f(\beta_n, \bar{\beta}_n) f(\alpha_n, \bar{\alpha}_n) + \text{reg.}$ (B.8)

Consider now the properties of $\Lambda^{(r)}_{n}(\bar{\alpha}_n | \bar{\beta}_n)$ in the same points. Obviously

$$
\Lambda^{(r)}_{n}(\bar{\alpha}_n | \bar{\beta}_n) = -q \alpha_n \beta_n h(\alpha_n, z) g(\beta_n, z) t(\alpha_n, \bar{\beta}_n) t(\bar{\alpha}_n, \beta_n) \\
\times h(\alpha_n, \bar{\alpha}_n) h(\alpha_n, \alpha_n) h(\beta_n, \beta_n) h(\bar{\beta}_n, \beta_n) \Lambda^{(l)}_{n-1}(\alpha_n | \bar{\beta}_n), \quad (B.9)
$$

where we have used $h(x, x) = x$. Taking the limit $\alpha_n \rightarrow \beta_n$ we obtain

$$
\Lambda^{(r)}_{n}(\bar{\alpha}_n | \bar{\beta}_n) = -q \alpha_n \beta_n h(\alpha_n, z) g(\beta_n, z) g(\bar{\beta}_n) g(\bar{\alpha}_n, \alpha_n) \\
\times h(\alpha_n, \bar{\alpha}_n) h(\alpha_n, \alpha_n) h(\beta_n, \bar{\beta}_n) h(\bar{\alpha}_n, \alpha_n) \Lambda^{(l)}_{n-1}(\alpha_n | \bar{\beta}_n) + \text{reg.} \quad (B.10)
$$

doi:10.1088/1742-5468/2015/03/P03019

23
Similarly, setting\(\alpha_n \rightarrow \beta_n q^{-2}\) we obtain
\[
\Lambda^{(r)}(\bar{\alpha}|\bar{\beta}) \bigg|_{\alpha_n=\beta_n q^{-2}} = -\frac{q^{-1} \beta_n^2}{h(\alpha_n, \beta_n)} g(\beta_n q^{-2}, \beta_n) h(\beta_n q^{-2}, z) g(\beta_n, z) t(\beta_n q^{-2}, \bar{\beta}_n) t(\bar{\alpha}_n, \alpha_n q^2) \]
\[
\times h(\alpha_n, \bar{\alpha}_n) h(\alpha_n, \alpha_n) h(\beta_n, \bar{\beta}_n) h(\bar{\beta}_n, \beta_n) \Lambda^{(r)}_{n-1}(\bar{\alpha}_n|\bar{\beta}_n) + \text{reg.}
\] (B.11)

Using (2.6) and
\[
\frac{q^{-1} \beta_n}{h(\alpha_n, \beta_n)} = f(\alpha_n, \beta_n q^{-2}) \bigg|_{\alpha_n=\beta_n q^{-2}},
\] (B.12)
we immediately recast (B.11) as follows
\[
\Lambda^{(r)}(\bar{\alpha}|\bar{\beta}) \bigg|_{\alpha_n=\beta_n q^{-2}} = f(\alpha_n, \beta_n q^{-2}) f(\bar{\alpha}_n, \alpha_n) f(\beta_n, \bar{\beta}_n) \Lambda^{(r)}_{n-1}(\bar{\alpha}_n|\bar{\beta}_n) + \text{reg.}
\] (B.13)

Now everything is ready for induction over\(n\). Assume that
\[
\Lambda^{(l)}_{n-1}(\bar{\alpha}_n|\bar{\beta}_n) = \Lambda^{(r)}_{n-1}(\bar{\alpha}_n|\bar{\beta}_n).
\] (B.14)

It is straightforward to check that (B.14) does hold for\(n = 2\). Due to the induction assumption and due to equations (B.5), (B.8), (B.10) and (B.13) the difference\(\Lambda^{(l)}(\bar{\alpha}|\bar{\beta}) - \Lambda^{(r)}(\bar{\alpha}|\bar{\beta})\) is a bounded function of\(\alpha_n\) in the whole complex plain. It is also easy to see that this function is bounded as\(\alpha_n \rightarrow \infty\). Hence, it is a constant with respect to\(\alpha_n\). But this constant vanishes at\(\alpha_n = 0\), hence,\(\Lambda^{(l)}(\bar{\alpha}|\bar{\beta}) - \Lambda^{(r)}(\bar{\alpha}|\bar{\beta}) = 0\).

\[\square\]
