On Extensionality of $\lambda$*

Andrew Polonsky

January 7, 2014

Abstract

We prove an extensionality theorem for the “type-in-type” dependent type theory with $\Sigma$-types. We suggest that the extensional equality type be identified with the logical equivalence relation on the free term model of type theory.

1 Introduction

The Extensionality Theorem of simple type theory states that all definable terms preserve a given relation $R_A$ on the free model of type theory, provided this relation is logical. In this context, logical means that the relation is generated in a very specific way from the base types by induction on the type structure. In particular, for the function type $A \rightarrow B$, the relation is to be given by

$$R_{A \rightarrow B} f f' \iff (\forall a a' : A) R_A a a' \rightarrow R_B (fa)(f'a')$$

The theorem has its origins in the Tarski–Sher thesis on the invariance of truth-valued operations (Feferman (2010), Tarski and Corcoran (1986), Sher (1991)). The first application of what came to be known as logical relations technique was given by Gandy (1956) in the proof of relative consistency of the axiom of extensionality in Church’s theory of types. However, it is only fairly recently that William Tait (1995) suggested that the notion of extensional equality in type theory be identified with the meta-level equivalence relation between terms defined by induction on type structure. By a logical relations argument, Tait proceeded to show that every term is indeed extensional, ie, preserves the semantic equivalence relation. As a consequence, every closed term is related to itself by this relation, giving a a computational justification for introducing the reflexivity operator for extensional equality.

Tait’s ideas remain relatively little-known. In light of the recent attention received by issues of extensional identity, we think this is a good time to explicitly announce the following

Extensionality Thesis. The extensional equality of type theory is the logical equivalence relation between elements of the term model defined by induction on type structure.
In this note, we shall generalize Tait’s extensionality theorem to dependent type theory with the universe of all types being itself a type. This system is known as $\lambda^*$. It is a pure type system which includes $\Sigma$-types in addition to $\Pi$. (A $\Pi\Sigma$-system, in the lexicon of Terlouw (1995).)

Our result is closely related to the well-known theory of parametricity, which generalizes Reynolds’ Abstraction Theorem for the polymorphic lambda calculus to the dependent case. For the PTS formulation of dependent type theory, the general result is proved by Bernardy and Lasson (2011). For the Logical Frameworks formulation, it is proved by Rabe and Sojakova (2013).

The central difference between the above results and ours consists in the treatment of universes. In parametricity theory, one associates to every type a relation $R_A : A \rightarrow A \rightarrow \text{Type}$ (which in general can have arbitrary arity). In the case of the universe $\ast$, a relation between two types $A, B : \ast$ is just that — a term of type $A \rightarrow B \rightarrow \text{Type}$. So $R_\ast AB$ is just the type of relations between $A$ and $B$.

In our case, we want the relation on the universe to be a (1-dimensional) equivalence of types, which means that a term of type $R_\ast AB$ is not merely a relation, but a relation satisfying certain additional properties. We give a formulation of these properties in the language of Induction–Recursion (Dybjer and Setzer (1999)), and prove a strict extensionality theorem for $\lambda^*$.

1.1 The simply typed case

We begin by recalling an elementary fact about the simply typed $\lambda$-calculus.

The syntax of simple types and typed terms is as follows:

$$
\mathbb{T} = o \mid \mathbb{T} \rightarrow \mathbb{T} \mid \mathbb{T} \times \mathbb{T}
$$

$$
\Lambda = x \mid \lambda x : \mathbb{T}. \Lambda \mid \Lambda \Lambda
$$

$$
\mid (\Lambda, \Lambda) \mid \pi_1 \Lambda \mid \pi_2 \Lambda
$$

A model of $\lambda_\ast$ consists of a family of sets $\{ X_A \mid A \in \mathbb{T} \}$ where

$$
X_{A \rightarrow B} \subseteq X_A^B
$$

$$
X_{A \times B} \subseteq X_A \times X_B
$$

are such that $X_{A \rightarrow B}$ is closed under abstraction of terms of type $B$ over variables of type $A$, and $X_{A \times B}$ is closed under pairs of definable elements of $X_A$ and $X_B$.

The interpretation of types is given by

$$
[A] = X_A
$$

The interpretation of terms is parametrized by an environment $\rho = \{ \rho_A : V_A \rightarrow X_A \}$, assigning elements of the domain to the free variables of the term.

Let $\mathbf{Env}$ be the set of such collections of functions.
A term $t : A$ is interpreted as a map $[t] : \text{Env} \to [A]$. We write $[t]_\rho$ for $[t](\rho)$. The definition of $[t]_\rho$ is given by induction:

$$
[x : A]_\rho = \rho_A(x)
$$

$$
[s t]_\rho = [s]_\rho [t]_\rho
$$

$$
[\lambda x : A. t]_\rho = (a \mapsto [t]_{\rho, x = a})
$$

$$
[(s, t)]_\rho = ([s]_\rho, [t]_\rho)
$$

$$
[\pi_i t]_\rho = a_i, \text{ where } [t]_\rho = (a_1, a_2) \in [[A_1 \times A_2]]
$$

A relation $R = \{ R_A : [A] \to [A] \to \text{Type} \mid A \in \mathbb{T} \}$ is said to be logical if

$$
R_{A \to B} f f' \iff \forall \alpha a' : X_A. R_{Aa'} \Rightarrow R_B(\alpha a')
$$

$$
R_{A \times B} (a, b) (a', b') \iff R_{Aa} \land R_{Bb'}
$$

**Theorem 1.** (Extensionality Theorem) Let $R$ be logical. Suppose that $t$ is a typed term:

$$
x_1 : A_1, \ldots , x_n : A_n \vdash t : T
$$

and let there be given

$$
a_1, a'_1 \in [A_1], \ldots , a_n, a'_n \in [A_n]
$$

Then

$$
a_1 R_{A, a'_1}, \ldots , a_n R_{A, a'_n} \Rightarrow [t]_{\bar{x} = \bar{a}} R_T [t]_{\bar{x} = \bar{a}'}
$$

In other words, every typed $\lambda$-term induces a function which maps related elements to related elements. As a corollary, we get that a closed term $t \in \Lambda^0(A)$ is $R_A$-related to itself.

We also note that if a given relation $R_\circ$ on the basic type is reflexive (symmetric, transitive), then its logical extension to the full type structure is also reflexive (symmetric, transitive). In particular, any equivalence given on $X_\circ$ can be extended to the interpretation of all types $X_A$ by the logical conditions. Then the elements in the model which are defined by $\lambda$-terms will preserve the equivalence relation on the corresponding types.

The proof of the above theorem proceeds by induction on the structure of derivation that $t : T$. We do abstraction case as an example. If $t = \lambda x : A. t'$, we have

$$
x_1 : A_1, \ldots , x_n : A_n, x : A \vdash t' : B
$$

$$
x_1 : A_1, \ldots , x_n : A_n \vdash \lambda x : A. t' : A \to B \quad \text{Abs}
$$

Let $(a_1, \ldots , a_n), (a'_1, \ldots , a'_n) : A_1 \times \cdots \times A_n$ be such that $a_i R_{A, a'_i}$. Assume $a, a' : A$ are given, and suppose that $a R_{A, a'}$.

By induction hypothesis,

$$
[t']_{x_1 = a_1 \cdots x_n = a_n} R_B [t']_{x_1 = a'_1 \cdots x_n = a'_n, a}
$$
which can be rewritten as

\[ \llbracket \lambda x.t' \rrbracket_{x_1 = a_1 \ldots x_n = a_n} (a) R_B \llbracket \lambda x.t' \rrbracket_{x_1 = a'_1 \ldots x_n = a'_n} (a') \]

Since \( a, a' \) were arbitrary, and \( R_{A \rightarrow B} \) is logical, it follows that

\[ R_{A \rightarrow B} \llbracket \lambda x.t' \rrbracket_{x_1 = a_1 \ldots x_n = a_n} \llbracket \lambda x.t' \rrbracket_{x_1 = a'_1 \ldots x_n = a'_n} \]

The other cases are treated similarly.

We note that the structure of the proof that \( t R_T t \) recapitulates rather precisely the structure of \( t \) itself. In particular, the theorem is completely constructive. Anticipating the dependent development below, consider a constructive reading of the theorem’s statement:

From a proof \( a_1^* \) that \( a_1 R_{A_1} a'_1 \)
and a proof \( a_2^* \) that \( a_2 R_{A_2} a'_2 \)
...  
and a proof \( a_n^* \) that \( a_n R_{A_n} a'_n \)  
Get a proof \( t(a_1^*, \ldots, a_n^*) \)  
that \( t(a_1, \ldots, a_n) R_T t(a_1', \ldots, a_n') \)

This motivates us to think of the above extensionality property as an operation which, given terms which relate elements in the context, substitutes these connections into \( t \) to get a relation between the corresponding instances of \( t \).

In this interpretation, the proof that a closed term \( t \) is related to itself

\[ t(t) : t R_T t \]

has specific computational content. Furthermore, the algorithm associated to this proof has the same structure as \( t \) itself.

2 The dependent case

To make matters simple, we use PTS formulation of dependent type theory with “type-in-type”. This system is denoted as \( \lambda^* \). It has a universal type \( * \), the type of all types. This allows us to unify into one the three classical judgement forms of dependent type theory:

\[ \Gamma \vdash A \textbf{ Type} \]  
\[ \Gamma \vdash a : A \]  
\[ \Gamma \vdash B : (A) \textbf{ Type} \]

The judgment \( \Gamma \vdash A \textbf{ Type} \) is replaced by \( \Gamma \vdash A : * \). Similarly, \( \Gamma \vdash (A)B \textbf{ Type} \) is replaced by \( \Gamma, x : A \vdash B : * \). Thus types and terms of type \( * \) are completely identified.
The syntax of $\lambda^*$, the type-in-type PTS with $\Sigma$-types\footnote{We call the system a “PTS” because its notion of equality is based on untyped conversion of lambda terms. Classically, $\Sigma$ types are not part of the PTS formalism, but including them here presents no difficulty.} is

$$t ::= * \mid x \mid \Pi x: A. B(x) \mid \Sigma x: A. B(x) \mid \lambda x: A. t(x) \mid st \mid (s, t) \mid \pi_1 t \mid \pi_2 t$$

A notational note: the parentheses following the matrix of the $\Pi$, $\Sigma$, and $\lambda$ constructors are not part of the syntax, and merely pronounce the fact that the term may depend on the variables in question. In general, when we write $t = t(x_1, \ldots, x_n)$, we do not commit to having displayed all the free variables of $t$; it is never mandatory to display a free variable.

The purpose of this notation is merely to reduce clutter in anticipation of substitution of $t$ by an instance of (some of the) variables. Our general notation for substituting a free variable $x$ in $t$ by $a$ is

$$t[a/x]$$

In particular, if $t = t(x_1, \ldots, x_n)$, then

$$t[a_1/x_1][a_n/x_n] = t(a_1, \ldots, a_n)$$

In the following development, we shall consider the open term model of the above type theory, using the same theory as our meta-level. To simplify notation, we write $[A]$ simply as $A$. As well, if $t(x_1, \ldots, x_n) : T(x_1, \ldots, x_n)$, then $[t]_{x_1, \ldots, x_n := a_1, \ldots, a_n}$ is denoted as $t(a_1, \ldots, a_n)$.

The only axiom of this type system has the form $* : *$, asserting that the universe of types $*$ is itself a type. Its intuitive meaning is

The collection of structures which types are interpreted by forms the same kind of structure.

In particular, if types are interpreted by types-with-relation $R_A : A \to A \to *$, then this interpretation must also include a relation on the universe of types

$$R_* : * \to * \to *$$

But how should this relation interact with objects inhabiting related types?

To answer this question, let us consider how the previous extensionality theorem could be extended to the dependent case. Suppose we are given terms

$$x : A \vdash B(x) : * \quad (1)$$
$$x : A \vdash b(x) : B(x) \quad (2)$$

If we are now given $a : A$, $a' : A$, we want to conclude that

$$R_A aa' \to R_B b(a)b(a') \quad (3)$$
However, the two terms \( b(a) \) and \( b(a') \) have different types! We need additional structure to formulate extensionality of dependent maps.

Looking again at (1), observe that, by extensionality, from any witness \( a^* \) of the hypothesis of (3), it should be possible to construct a witness \( B(a^*) \) to the relation \( R_e B(a) B(a') \). The relation between \( b(a) \) and \( b(a') \) can then be construed as lying over the relation between \( B(a) \) and \( B(a') \). This suggests the following principle:

Every witness \( E : R_e A B \) to the fact that \( A \) and \( B \) are related elements of the universe induces a relation

\[
\tilde{E} : A \rightarrow B \rightarrow \ast
\]

between elements of corresponding types.

Let \( e : R_e A B \) be given. In the sequel, we often write \( \tilde{e}ab \) as \( a \sim_e b \). This relation should have the following properties:

- For any \( a : A \), there exists an element \( e(a) : B \) which is \( R_B \)-minimal with respect to all elements \( b \) which are \( \sim_e \)-related to from \( a \); thus
  \[
  \begin{align*}
  &- a \sim_e e(a) \\
  &- a \sim_e b \Rightarrow e(a)R_B b
  \end{align*}
  \]

- For any \( b : B \), there exists an element \( \bar{e}(b) : A \) which is \( R_A \)-maximal with respect to all elements \( a \) which are \( \sim_e \)-related to \( b \):
  \[
  \begin{align*}
  &- \bar{e}(b) \sim_e b \\
  &- a \sim_e b \Rightarrow aR_A \bar{e}(b)
  \end{align*}
  \]

- Whenever \( e(a) \) is related to \( b \), \( a \) is related to \( b \). Whenever \( a \) is related to \( \bar{e}(b) \), \( a \) is related to \( b \). Thus the two implications above are invertible.

(We remark that, if the relations in question are assumed to be reflexive and transitive, then the above conditions on \( \tilde{e} \) define a connection between \( A \) and \( B \) in the sense of order theory:

\[
\begin{align*}
\lambda x : A. e(x) : A \rightarrow B \\
\lambda y : B. \tilde{e}(y) : B \rightarrow A \\
\forall x : A \forall y : B \quad xR_A \tilde{e}(y) \iff e(x)R_B y
\end{align*}
\]

So — if \( x : A \vdash B(x) : \ast \), and \( a^* : aR_A a' \), we have \( B(a^*)^{-} : B(a) \rightarrow B(a') \rightarrow \ast \).

We now say that a family of relations \( \{ R_A : A \rightarrow A \rightarrow \ast \mid A : \ast \} \) is logical if:

\[
R_{\Pi x : A. B(x)} f f' = \prod_{a : A} \prod_{a' : A} \Pi a^* : R_A a a'. B(a^*)^{-} (f a)(f' a') \tag{4}
\]

\[
R_{\Sigma x : A. B(x)} p p' = \Sigma a^* : R_A (\pi_1 p)(\pi_1 p'). B(a^*)^{-} (\pi_2 p)(\pi_2 p') \tag{5}
\]

The general statement of extensionality will take the following form:
Theorem 2. Let \( \{R_A\} \) be logical. For every term \( t \) typed in the context

\[
x_1 : A_1, \ldots, x_n : A_n(x_1, \ldots, x_{n-1}) \vdash t(x_1, \ldots, x_n) : T(x_1, \ldots, x_n)
\]

and for any pair of coordinate-wise related instances

\[
a_1 : A_1, \ldots, a_n : A_n(a_1, \ldots, a_{n-1})
a'_1 : A_1, \ldots, a'_n : A_n(a'_1, \ldots, a'_{n-1})
a^*_1 : R_A, a_1 a'_1, \ldots, a^*_n : A_n(a^*_1, \ldots, a^*_{n-1}) \sim a_n a'_n
\]

there is a witness \( t(a^*_1, \ldots, a^*_n) \) to the fact that

\[
t(a_1, \ldots, a_n) \sim_{T(a^*_1, \ldots, a^*_n)} t(a'_1, \ldots, a'_n).
\]

In particular, when \( t : T \) is a closed term, the above principle yields a new term \( t() : t \sim_{T()} t \) which is not quite the same as \( t \), because it is one dimension higher. Let us instead write \( t^* \) for this term. For such closed terms, we get

\[
t^* : t \sim_{T^*} t
\]

\[
T^* : T \sim_{\star^*} T
\]

\[
\star^* : \star \sim_{\star^*} \star
\]

This suggests an answer to the question of what should be the logical condition on the universe constant \( \star \). We should have that

\[
\forall A : \star \quad a R_A a' \iff a \sim_{\star} a'
\]

In particular,

\[
AR_\star B \iff A \sim_{\star} B
\]

The problem with the statement of dependent extensionality theorem above is that the formula in the conclusion already makes reference to the result of the substitution of \( a^*_1, \ldots, a^*_n \) into \( T(\vec{x}) \), which requires the extensionality of the judgement \( \Gamma \vdash T(\vec{x}) : \star \) to be known beforehand. In general, the proof of this fact will again depend on extensionality of subterms appearing in \( T \).

We therefore move to first represent the type universe of \( \lambda \star \) in a minimal extension of the system relevant for this purpose. The above theorem will be stated for the result of reflecting the meta-level into this universe. The next step is to mutually define the type of equivalences between two elements of this universe, and the corresponding relations induced by such equivalences. The inter-dependency between these concepts is resolved using an indexed inductive–recursive definition of [Dybjer and Setzer (2001)], and this allows us to state the above theorem for the (reflected) universe. Finally, we prove the theorem by induction on the structure of derivations.
The inductive–recursive definition of the universe $U$ of $\lambda\ast$-types is as follows:

Inductive $U : \ast \colon$

| $\prod : \Pi A : U. (TA \to U) \to U$
| $\sum : \Pi A : U. (TA \to U) \to U$
| $\otimes : U$

with $T : U \to \ast \colon$

$T(\prod AB) = \Pi a : TA. T[a]$ 
$T(\sum AB) = \Sigma a : TA. T[a]$ 
$T(\otimes) = U$

Let $\lambda\ast U$ be $\lambda\ast$ augmented with the above datatype. Notice that every derivation in $\lambda\ast$ is also a derivation in $\lambda\ast U$.

**Definition 3.** We define a map $\bar{\cdot}$ from the raw terms of $\lambda\ast$ to the raw terms of $\lambda\ast U$ as follows:

- $\bar{\ast} = \otimes$
- $\bar{x} = x$
- $\bar{\Pi x : A. B} = \prod A (\lambda x : TA. B)$
- $\bar{\Sigma x : A. B} = \sum A (\lambda x : TA. B)$
- $\bar{\lambda x : A. t} = \lambda x : A. \bar{t}$
- $\bar{st} = s\bar{t}$
- $\bar{(s, t)} = (\bar{s}, \bar{t})$
- $\bar{\pi_1s} = \pi_1\bar{s}$

**Definition 4.** Suppose $\Gamma = \{x_1 : A_1, \ldots, x_n : A_n\}$. We define

$\bar{\Gamma} := \{x_1 : TA_1, \ldots, x_n : TA_n\}$

**Lemma 5.** *(Substitution Lemma)* Let $M, N$ be $\lambda\ast$-terms. Then

$M[N/x] = \bar{M}[\bar{N}/\bar{x}]$

**Corollary 6.** Let $M = N$ be $\lambda\ast$-terms. Then

$M = N \implies \bar{M} = \bar{N}$

**Theorem 7.** *(Reflection of $\ast$ into $U$)*

$\Gamma \vdash_{\lambda\ast} M : A \implies \bar{\Gamma} \vdash_{\lambda\ast U} \bar{M} : T\bar{A}$

**Proof.** The translation is done by induction on $\Gamma \vdash M : A$. 

8
Axiom \( \vdash_{\lambda^*} * : * \). Then \( \overline{\Gamma} = \Gamma = () \). Also \( \overline{A} = \overline{M} = \emptyset \).

The conversion rule gives

\[
\begin{array}{c}
\emptyset : U \\
\overline{T} : * \\
U = T \emptyset
\end{array}
\]

Thus indeed \( \vdash_{U} \overline{M} : T \overline{A} \).

Variable Suppose \( \delta \) ends with

\[
\Gamma \vdash A : * \\
\Gamma, x : A \vdash x : A
\]

By induction hypothesis, we have

\( \Gamma \vdash \overline{A} : U \)

Hence \( \Gamma \vdash \overline{A} : U \), and \( \Gamma \vdash T \overline{A} : * \) By the variable rule, we have

\( \Gamma, x : T \overline{A} \vdash x : T \overline{A} \)

Weakening Let the derivation end with

\[
\begin{array}{c}
\Gamma \vdash M : A \\
\Gamma \vdash B : *
\end{array}
\]

By induction hypothesis, we have

\( \Gamma \vdash \overline{M} : T \overline{A} \)

\( \Gamma \vdash \overline{B} : T \emptyset \)

That is, \( \overline{\Gamma} \) yields \( \vdash \overline{B} : U \). Then \( T \overline{B} : * \). By weakening,

\( \Gamma, y : T \overline{B} \vdash \overline{M} : T \overline{A} \)

\( \Pi \)-formation Given

\[
\begin{array}{c}
\Gamma \vdash A : * \\
\Gamma, x : A \vdash B : *
\end{array}
\]

the induction hypotheses yield

\( \Gamma \vdash \overline{A} : T \overline{T} \)

\( \Gamma, x : T \overline{A} \vdash \overline{B} : T \overline{T} \) (6)

(7)

Since \( \overline{A}, \overline{B} : T \overline{T} = T \emptyset = U \), we have \( \Gamma \vdash T \overline{A} : * \) as well as \( \Gamma, x : T \overline{A} \vdash T \overline{T} : * \).
By the Π-introduction rule, (7) yields
\[ \Gamma \vdash \lambda x : T.\overline{A} : \overline{T}A \rightarrow U \]
whence Π-elimination together with (6) yields
\[ \Gamma \vdash \overline{A}(\lambda x : T\overline{A}\overline{B}) : U \]
That is,
\[ \Gamma \vdash \Pi x : A.B : T\overline{T} \]

**Σ-formation** Treated in an analogous fashion.

**Π-introduction** Suppose the derivation is of the form
\[
\begin{align*}
\Gamma \vdash A : * & \quad \Gamma, x : A \vdash B : * \quad \Gamma, x : A \vdash b : B \\
\Gamma \vdash \lambda x : A.b : \Pi x : A.B
\end{align*}
\]
The induction hypotheses give us
\[
\begin{align*}
\Gamma \vdash \overline{A} : T\overline{T} & \\
\Gamma, x : T\overline{A} \vdash \overline{B} : T\overline{T} & \\
\Gamma, x : T\overline{A} \vdash \overline{b} : T\overline{B}
\end{align*}
\]
(8)
As in the previous case, we actually have
\[
\begin{align*}
\Gamma \vdash \overline{A} : U & \quad \Gamma \vdash T\overline{A} : * \\
\Gamma, x : T\overline{A} \vdash \overline{B} : U & \quad \Gamma, x : T\overline{A} \vdash T\overline{B} : * \\
\Gamma \vdash \Pi x : A.B : U & \quad \Gamma \vdash T[\Pi x : A.B] : *
\end{align*}
\]
By Π-introduction on (8), we have
\[ \Gamma \vdash \lambda x : T\overline{A}\overline{b} : \Pi x : T\overline{A}.T\overline{B} \]
But we also find that
\[ \Pi x : T\overline{A}.T\overline{B} = T[\overline{A}(\lambda x : T\overline{A}\overline{B})] = T\Pi x : A.B \]
(9)
and so conclude that
\[ \Gamma \vdash \lambda x : A.b : T\Pi x : A.B \]

**Π-elimination** Suppose we are given
\[
\begin{align*}
\Gamma \vdash A : * & \quad \Gamma, x : A \vdash B : * \quad \Gamma \vdash f : \Pi x : A.B \quad \Gamma \vdash a : A \\
\Gamma \vdash fa : B[a/x]
\end{align*}
\]
The induction hypothesis yield, on the one hand, that

\[
\begin{align*}
\Gamma &\vdash A : U \\
\Gamma, x : T\overline{A} &\vdash B : U \\
\Gamma &\vdash \Pi x : A.B : U \\
\Gamma &\vdash \Pi\overline{A} : * \\
\end{align*}
\]

and on the other hand, that

\[
\begin{align*}
\Gamma &\vdash f : \Pi\overline{A} \\
\Gamma &\vdash a : T\overline{A} \\
\end{align*}
\]

Since \(f\) by conversion in (9) has type \(\Pi x : T\overline{A}.T\overline{B}\), we may write

\[
\Gamma \vdash f \bar{a} : T\overline{B}[\bar{a}/x]
\]

By Lemma 5, the type in the above judgment is equal to \(T\overline{B}[a/x]\).

**Σ-introduction** When we are at

\[
\begin{align*}
\Gamma &\vdash A : * \\
\Gamma, x : A &\vdash B : * \\
\Gamma &\vdash a : A \\
\Gamma &\vdash b : B[a/x] \\
\end{align*}
\]

the induction hypotheses give as before that

\[
\begin{align*}
\Gamma &\vdash \overline{A} : * \\
\Gamma, x : T\overline{A} &\vdash T\overline{B} : * \\
\end{align*}
\]

and, in addition, we also have

\[
\begin{align*}
\Gamma &\vdash \overline{a} : T\overline{A} \\
\Gamma &\vdash \overline{b} : T\overline{B}[a/x] \\
\end{align*}
\]

Recall that

\[
\begin{align*}
\Sigma x : A.B &= \overline{A}(\lambda x : T\overline{A}.B) \\
T\Sigma x : A.B &= \Sigma x : T\overline{A}.T\overline{B}
\end{align*}
\]

By Lemma 5 \(T\overline{B}[a/x] = T\overline{B}[\bar{a}/x]\). Hence \(b : T\overline{B}[\bar{a}/x]\).

By Σ-introduction, we now obtain

\[
\begin{align*}
\Gamma &\vdash (\overline{a}, \overline{b}) : \Sigma x : T\overline{A}.T\overline{B}
\end{align*}
\]

In other words, \(\Gamma \vdash (a, b) : T\Sigma x : A.B\).

**Σ-elimination** Let there be derived
\[\Gamma \vdash A : * \quad \Gamma, x : A \vdash B : * \quad \Gamma \vdash p : \Sigma x : A. B\]
\[\Gamma \vdash \pi_1p : A\]
\[\Gamma \vdash \pi_2p : B[\pi_1p/x]\]

Assume we have
\[\Gamma \vdash A : U\]
\[\Gamma, x : T \overline{A} \vdash \overline{B} : U\]
\[\Gamma \vdash p : T \Sigma x : A. B\]

We have just seen that \(T \Sigma x : A. B = \Sigma x : T \overline{A}. T \overline{B}\). Thus
\[\pi_1p : \overline{A}\]
\[\pi_2p : [T \overline{B}][\pi_1p/x]\]

The subjects of these judgements can be rewritten as \(\overline{\pi_1p}\).

Also
\[\overline{[T \overline{B}][\pi_1p/x]} = \overline{[T \overline{B}][\pi_1p/x]} = \overline{T}[\overline{[\pi_1p/x]}] = \overline{T}[\overline{\pi_1p}/x]\]

Thus we have
\[\Gamma \vdash \pi_1p : \overline{A}\]
\[\Gamma \vdash \pi_2p : \overline{T B}[\pi_1p/x]\]

**Conversion** Suppose we come across
\[\Gamma \vdash M : A \quad \Gamma \vdash B : * \quad A = B\]

By induction hypothesis, we have
\[\Gamma \vdash \overline{M} : T \overline{A}\]
\[\Gamma \vdash \overline{B} : U\]

By Lemma 6 we have
\[\overline{A} = \overline{B}\]

But clearly that implies that
\[T \overline{A} = T \overline{B}\]

It is likewise clear that
\[\Gamma \vdash T \overline{B} : *\]

By the conversion rule, we comprehend
\[\Gamma \vdash \overline{M} : T \overline{B}\]

This completes the proof of the theorem. \(\Box\)
4 Extensionality of $\lambda*$

We work in $\lambda*U$. Assume as given a relation

$$R : \Pi A : U.TA \to TA \to *$$

At this point we begin to denote $RA$ by the symbol

$$A^\approx : TA \to TA \to *$$

and we shall often write $A^\approx aa'$ as $a \sim_A a'$.

We also require that every inhabitant $e$ of $\circlearrowright AB$ gives rise to a relation

$$e : TA \to TB \to *$$

and we often write $e^\approx ab$ as $a \sim_e b$.

For the notion of equivalence of types, we assume as given a binary relation on the type $U$:

$$\approx : U \to U \to U$$

and we write $A \approx B$ for $\approx AB$. This notation is consistent, because we shall stipulate that

$$A \approx B = A \approx_e B$$

In order to precisely state extensionality theorem using the above data, we must provide answers to the following questions:

- What does it mean for two types $A, B : U$ to be equivalent?

- What does it mean for two elements to be related by an equivalence?

To answer these questions, we proceed as in Section 2. We identify the notion of equivalence with the notion of a binary relation with certain properties. Semantically, $e$ is an equivalence between $A$ and $B$ if $e \subseteq \llbracket A \rrbracket \times \llbracket B \rrbracket$, and $e$ satisfies those additional properties.

In order to represent equivalences in type theory, we must therefore introduce a syntax for defining such binary relations between two types.

That is, for any two terms $A, B : U$, we must introduce a type of codes of equivalences from $A$ to $B$. This type will be denoted as

$$Eq(A, B)$$

Simultaneously with this type, we must also define a function which evaluates the codes to actual relations between the types $A$ and $B$. Ie, we need a map

$$\Rel : Eq(A, B) \to TA \to TB \to *$$

This suggests that the type constructors $\approx$ and $\sim_e$ can be captured using a variant of the inductive–recursive (IR) definitions.

Upon reflecting on this possibility, it shall become manifest that the two concepts above cannot be defined uniformly in $A$ and $B$; rather, the $A$ and $B$
must take part in the recursive construction of both the set \( \mathcal{E}q(A, B) \) as well as the map \( \mathcal{R}el \). Thus, the arguments \( A \) and \( B \) are to be treated as indices, so that we are dealing with an indexed inductive–recursive definition (IIRD).

We are now in the position to answer the two questions posed above. The notion of equivalence of types \( A \) and \( B \) and the notion of elements of the corresponding types being related over this equivalence are both defined simultaneously by indexed induction–recursion. The definition follows.

**Inductive** \( \mathcal{E}q : U \rightarrow U \rightarrow * :=
\]
\[
| r(\circ) : \mathcal{E}q \circ \circ
\]
\[
| \circ \circ \{ AA' : U \} \{ B : A \rightarrow U \} \{ B' : A' \rightarrow U \}
\]
\[
(A' : \mathcal{E}q AA')(B' : \Pi a : AA' : A' \Pi a' : \mathcal{R}el A' a a'. Ba = B' a')
\]
\[ : \mathcal{E}q (\bigcirc A B)(\bigcirc A' B')
\]
\[
| \circ \circ \{ AA' : U \} \{ B : A \rightarrow U \} \{ B' : A' \rightarrow U \}
\]
\[
(A' : \mathcal{E}q AA')(B' : \Pi a : AA' : A' \Pi a' : \mathcal{R}el A' a a'. Ba = B' a')
\]
\[ : \mathcal{E}q (\bigcirc A B)(\bigcirc A' B')
\]
with \( \mathcal{R}el : \Pi \{ A \} \{ B \} : U. \mathcal{E}q AB \rightarrow TA \rightarrow TB \rightarrow *
\]
\[
\mathcal{R}el((r(\circ))) AB = \mathcal{E}q AB
\]
\[
\mathcal{R}el(\circ \circ A^* B^*) f f' = \Pi x : A A' : A' \Pi x' : \mathcal{R}el A^* xx'.
\]
\[
\mathcal{R}el(B^* xx' x'')(f x)(f' x')
\]
\[
\mathcal{R}el(\circ \circ A^* B^*) p p' = \Sigma x^* : \mathcal{R}el A^* (\pi_1 p)(\pi_1 p').
\]
\[
\mathcal{R}el(B^* (\pi_1 p)(\pi_1 p') x^*)(\pi_2 p)(\pi_2 p')
\]

We denote the system \( \lambda^{*} U \) extended with the above IIRD by \( \lambda^{*} U\approx \).

We remark that \( \lambda^{*} U \) is a subsystem of \( \lambda^{*} U\approx \) in the sense that every term of \( \lambda^{*} U \) is a term of \( \lambda^{*} U\approx \), and every derivation in \( \lambda^{*} U \) is also a derivation in \( \lambda^{*} U\approx \).

**Definition 8.** We define two operations on those terms of \( \lambda^{*} U \) which are in the image of the reflection map \( \tau : \lambda^{*} \rightarrow \lambda^{*} U \).

Thus, the operations are really defined on terms of form \( \overline{M} \) or \( (T)^{\overline{A}} \), but for notational convenience we shall write these as \( M \) and \( A \) just as well.

The first operation marks every variable with an apostrophe:

\[
(\cdot)' : \text{Terms}(\lambda^{*} U) \rightarrow \text{Terms}(\lambda^{*} U)
\]
\[ \otimes' = \otimes \]
\[ (x)' = x' \]
\[ (\otimes AB)' = \otimes A'B' \]
\[ (\otimes AB)' = \otimes A'B' \]
\[ (\lambda x:A.b)' = \lambda x':A'b' \]
\[ (st)' = s't' \]
\[ (s, t)' = (s', t') \]
\[ (\pi_1p)' = \pi_1p' \]
\[ (\pi_2p)' = \pi_2p' \]

The second operation substitutes every type by an equivalence and every term by a higher-dimensional cell.

\[ (-)^* : \text{Terms}(\lambda*U) \to \text{Terms}(\lambda*U) \]

\[ (x)^* = x^* \]
\[ \otimes^* = r(\otimes) \]
\[ (\otimes AB)^* = \otimes' A' (\lambda x:A \lambda x':A' \lambda x^*: \mathcal{R} (A^* xx').B') \]
\[ (\otimes AB)^* = \otimes' A' (\lambda x:A \lambda x':A' \lambda x^*: \mathcal{R} (A^* xx').B') \]
\[ (\lambda x:A.b)^* = \lambda x:A \lambda x':A' \lambda x^*: \mathcal{R} (A^* xx').b^* \]
\[ (f a)^* = f^* a a' a^* \]
\[ (a, b)^* = (a^*, b^*) \]
\[ (\pi_1p)^* = \pi_1p^* \]
\[ (\pi_2p)^* = \pi_2p^* \]

**Theorem 9.** \( (M[N/x])' = M'[N'/x'] \)

**Theorem 10.** \( (M[N/x])^* = M^*[N/x, N'/x', N^*/x^*] \)

**Proof.** **Axiom** \( (\otimes [N/x])^* = (\otimes)^* = r(\otimes) = r(\otimes)[N/x, N'/x', N^*/x^*] \)

**Variable**

\[ (y[N/x])^* = \begin{cases} 
(x[N/x])^* = x^* = x^*[N/x, N'/x', N^*/x^*] & \text{if } y = x \\
(y[N/x])^* = y^* = y^*[N/x, N'/x', N^*/x^*] & \text{if } y \neq x 
\end{cases} \]

**Product**

\[ (\otimes AB [N/x])^* = (\otimes' A[N/x]B[N/x])^* \]
\[ = \otimes'(A[N/x])^*(B[N/x])^* \]
\[ = \otimes' A^*[N/x, N'/x', N^*/x^*]B'[N/x, N'/x', N^*/x^*] \]
\[ = (\otimes' A^* B^*)[N/x, N'/x', N^*/x^*] \]
Sum

\((\otimes AB[N/x])^* = (\otimes A[N/x]B[N/x])^*
= \otimes (A[N/x])^*(B[N/x])^*
= \otimes A^*[N/x, N'/x', N^*/x^*]B^*[N/x, N'/x', N^*/x^*]
= (\otimes A'B^*)[N/x, N'/x', N^*/x^*]

Abstraction

We remark that the Variable Convention can be observed.

\(((\lambda y:A.b)[N/x])^* = (\lambda y : A[N/x].b[N/x])^*
= \lambda y : A[N/x]\lambda y'(A[N/x])' \lambda y^* : Rq(A[N/x])^*y'y'.(b[N/x])^*
= \lambda y : A[N/x]\lambda y':A'[N'/x'] \lambda y^* : Rq A^*[N/x, N'/x', N^*/x^*]y'y'.
\quad b^*[N/x, N'/x', N^*/x^*]
= \lambda y : A[N', N^*/x, x', x^*] \lambda y':A'[N', N^*/x, x', x^*] \lambda y^* : (Rq A^*y'y')[N', N^*/x, x', x^*]
\quad b^*[N', N^*/x, x', x^*]
= (\lambda y : A\lambda y':A' \lambda y^* : Rq A^*y'y').b^*[N', N^*/x, x', x^*]
= (\lambda y : A.b)^*[N/x, N'/x', N^*/x^*]

Application

\((st[N/x])^* = (s[N/x]t[N/x])^*
= (s[N/x])(t[N/x])'(t[N/x])^*
= (s'^*[N', N'/x', x', x^*]t[N/x]t'[N'/x]t'*[N, N', N^*/x, x', x^*]
= (s'tt')*[N, N', N^*/x, x', x^*]
= (st)^*[N, N', N^*/x, x', x^*]

Pairing

\(((s, t)[N/x])^* = (s[N/x], t[N/x])^*
= ((s[N/x])^*, (t[N/x])^*)
= (s'^*[N/x, N'/x', N^*/x^*], t'^*[N/x, N'/x', N^*/x^*])
= (s'^*, t'^*)[N, N', N^*/x, x', x^*]
= (s, t)^*[N, N', N^*/x, x', x^*]

Projection

\(((\pi_i t)[N/x])^* = (\pi_i t[N/x])^*
= \pi_i(t[N/x])^*
= \pi_i(t'[N, N', N^*/x, x', x^*])
= \pi_i t*[N, N', N^*/x, x', x^*]
= (\pi_i t)^*[N, N', N^*/x, x', x^*] \square
Corollary 11. Suppose $M = N$. Then $M^* = N^*$.

Proof. Assume $M = (\lambda x:A.s)t$ and $N = s[t/x]$. We have

$$M^* = ((\lambda x:A.s)t)^* = (\lambda x:A.s)^*tt'\tau^*$$
$$= (\lambda x:A\lambda x':A'\lambda x^* : Rel A'^* xx', s^*)tt't^*$$
$$= s^*[t/x][t'/x'][t^*/x^*]$$
$$= (s[t/x])^* = N^*$$

where the last equality is by the previous proposition.

Now suppose that $M = \pi_i(t_1, t_2)$, and $N = t_i$. Then

$$M^* = \pi_i(t_1^*, t_2^*) = t_i^* = N^*$$

Definition 12. A $\lambda U$-context $\Gamma$ is said to be a $U$-context if $\Gamma$ is of the form

$$x_1 : TA_1, \ldots, x_n : TA_n(x_1, \ldots, x_{n-1})$$

and for $0 \leq i < n$, it holds that

$$x_i : TA_i(x_1, \ldots, x_i, x_{i-1})_i \vdash A_{i+1}(x_1, \ldots, x_i) : U$$

If $\Gamma$ is a $U$-context, and $\Gamma \vdash A : U$, we call $A$ a $U$-type in $\Gamma$.

Definition 13. Given a $U$-context $\Gamma = \{x_1 : TA_1, \ldots, x_n : TA_n\}$, put

$$\Gamma^* = \begin{cases} x_1 : TA_1, \ldots, x_n : TA_n, \\ x'_1 : TA'_1, \ldots, x'_n : TA'_n, \\ x^*_1 : Rel A^*_1 x_1 x'_1, \ldots, x^*_n : Rel A^*_n x_n x'_n \end{cases}$$

Let $\Gamma'$ be obtained from $\Gamma$ by apostrophizing every variable, including those occurring in their declared types. Obviously, we can have

Theorem 14. $\Gamma \vdash M : A \implies \Gamma' : M' : A'$.

Theorem 15. Let $\Gamma$ be a $U$-context, and $A$ a $U$-type in $\Gamma$. Then

$$\Gamma \vdash_{\lambda U} M : TA \implies \Gamma^* \vdash_{\lambda U} M^* : Rel A^* MM'$$

(10)

Proof. We proceed by induction on the derivation.

Axiom Suppose $\Gamma \vdash : T$. We have

$$\emptyset^* = r(\emptyset) : Eq\emptyset\emptyset = Rel r(\emptyset)\emptyset\emptyset = Rel \emptyset^* \emptyset^*$$

where $r(\emptyset) : Eq\emptyset\emptyset$ in any context.

By conversion rule, $\Gamma^* \vdash : Rel \emptyset^* \emptyset^*.$

Variable Suppose we have a derivation tree with root
\[
\frac{\Gamma \vdash A : T \otimes}{\Gamma, x : TA \vdash x : TA}
\]

(Notice that the hypothesis says that \(A\) is a \(U\)-type in \(\Gamma\).)

By the previous proposition, \(\Gamma' \vdash A' : T \otimes\).

By induction hypothesis, \(\Gamma^* \vdash A^* : \text{Rel} \otimes AA'\).

Since \(\text{Rel} \otimes AA' = \text{Eq} AA'\), we have \(\Gamma^* \vdash A^* : \text{Eq} AA'\) by conversion.

Yet \(\Gamma^*\) also yields that \(TA : *\) and \(TA' : *\), and thus we may form the context \(\Gamma^*, x : TA, x' : TA' \vdash\). In this context, we may derive that

\[
\frac{\Gamma^*, x : TA, x' : TA' \vdash \text{Rel} A x x'}{x^* : \text{Rel} A x x'}
\]

using the typing rule for the \(\text{Rel}\) constructor.

By the variable rule, we have

\[
\frac{\Gamma^*, x : TA, x' : TA', x^* : \text{Rel} A x x' \vdash x^* : \text{Rel} A x x'}{\Gamma^*, y : TB, y' : TB' \vdash y^* : \text{Rel} A y y'}
\]

The context in the above judgement is \((\Gamma, x : TA)^*\). The subject is \((x)^*\).

The type predicate is as displayed in [10].

**Weakening** Suppose they give you

\[
\frac{\Gamma \vdash M : TA \quad \Gamma \vdash B : T \otimes}{\Gamma, y : TB \vdash M : TA}
\]

The induction hypotheses give that

\[
\begin{align*}
\Gamma^* & \vdash M^* : \text{Rel} A^* MM' \\
\Gamma^* & \vdash B^* : \text{Rel} \otimes BB'
\end{align*}
\]

As before, we may conclude that \(B, B' : U\) in \(\Gamma^*\), that \(B^* : \text{Eq} BB'\), and that \(\Gamma^*, y : TB, y' : TB'\) is a valid context.

Then \(\text{Rel} B^* y y' : *\), and by weakening we get

\((\Gamma, y : TB)^* \vdash M^* : \text{Rel} A^* MM'\)

**Formation** Consider the typing

\[
\frac{\Gamma \vdash A : T \otimes \quad \Gamma, x : TA \vdash B : T \otimes}{\Gamma \vdash \Phi A(\lambda x : TA.B) : \otimes}
\]

By induction, \(\Gamma^* \vdash A^* : \text{Rel} \otimes AA'\).

By conversion, this gives \(\Gamma^* \vdash A^* : \text{Eq} AA'\).

We also have \((\Gamma, x : TA)^* \vdash B^* : \text{Rel} \otimes BB'\).
That gives \( \Gamma^*, x : TA, x' : TA', x^* : \text{Ref}\ A^* xx' \vdash B^* : \text{Eq}\ BB' \).

Using the abstraction rule, we derive
\[
\Gamma^* \vdash \lambda x : TA. \lambda x' : TA' . \lambda x^* : \text{Ref}\ A^* xx'. B^*
\]

which can be rewritten as
\[
\Gamma^* \vdash (\lambda x : TA. B)^* : \Pi x : TA \Pi x' : TA \Pi x^* : \text{Ref}\ A^* xx'. \text{Eq}\ BB'
\]

Using the \( \Pi^* \)-constructor, we may derive
\[
\Gamma^* \vdash \Pi A^*(\lambda x : TA. B)^* : \text{Eq}(\Pi A)(\Pi A'B')
\]

The subject of the above judgment is equal to
\[
(\Pi A(\lambda x : TA. B))^*
\]

while the type is convertible to \( \text{Ref}(r(\bigotimes))(\Pi AB)(\Pi A'B') \). Putting these together using the conversion rule yields
\[
\Gamma^* \vdash (\Pi A(\lambda x : TA. B))^* : \text{Ref}\ (\Pi AB)(\Pi AB)^*
\]

being of the required form.

By replacing \( \Pi \) with \( \Sigma \), \( \Pi^* \) with \( \bigotimes \), and \( \Pi^* \) with \( \bigodot^* \), we may derive from the same hypotheses that
\[
\Gamma^* \vdash (\bigodot A(\lambda x : TA. B))^* : \text{Ref}\ (\bigodot AB)(\bigodot AB)^*
\]

**Abstraction** If we have to do

\[
\begin{align*}
\Gamma \vdash A : T \bigotimes & \quad \Gamma, x : TA \vdash B : T \bigotimes & \quad \Gamma, x : TA \vdash b : TB \\
\Gamma \vdash \lambda x : TA.b : T(\Pi A(\lambda x : TA. B))
\end{align*}
\]

the induction hypotheses yield, with conversion, that
\[
\begin{align*}
\Gamma^* \vdash A^* : \text{Eq}\ AA' \\
\Gamma^*, x : TA, x' : TA', x^* : \text{Ref}\ A^* xx' \vdash B^* : \text{Eq}\ BB' \\
\Gamma^*, x : TA, x' : TA', x^* : \text{Ref}\ A^* xx' \vdash b^* : \text{Ref}\ B^* bb'
\end{align*}
\]

Since \( A, A' \) are \( U \)-types in \( \Gamma^* \), and \( \text{Ref}\ A^* xx' : * \), we can apply the abstraction rule three times in a row to see that the context
\[
(\Gamma, x : TA)^* = \Gamma^*, x : TA, x' : TA', x^* : \text{Ref}\ A^* xx'
\]
yields typing judgment
\[ \vdash \lambda x : T A \, \lambda x' : T A' \, \lambda x'' : \Pi x : T A \, \Pi x' : T A' \, \Pi x'' : \Pi x. \text{Ref} \, A^* \, x x'. \text{Ref} \, B^* \, b b' \]

The subject of this judgment is equal to \((\lambda x : T A. b)^*\).

The type predicate may be converted as
\[
\begin{align*}
\Pi x : T A \, \Pi x' : T A' \, \Pi x'' : \text{Ref} \, A^* \, x x'. \text{Ref} \, B^* ((\lambda x : T A. b)x) ((\lambda x' : T A'. b')x') \\
= \Pi x : T A \, \Pi x' : T A' \, \Pi x'' : \text{Ref} \, A^* \, x x'. \\
\text{Ref} ((\lambda x : T A. B)^* x x' x^*) ((\lambda x : T A. b)x) ((\lambda x' : T A'. b')x') \\
= \text{Ref} ((\Pi A (\lambda x : T A. B))^* (\lambda x : T A. b)(\lambda x : T A. b)' \\
= \text{Ref} (\Pi A (\lambda x : T A. B))^* (\lambda x : T A. b)(\lambda x : T A. b)'
\end{align*}
\]

which is of the form \( \text{II} \), as desired.

**Application** If the derivation ends with
\[
\begin{array}{c}
\Gamma \vdash A : T \oplus \\
\Gamma, x : T A \vdash B : T \oplus \\
\Gamma \vdash f : T (\Pi A (\lambda x : T A. B)) \\
\Gamma \vdash a : T A
\end{array}
\]

\[ \Gamma \vdash f a : B [a/x] \]

We thus have that that \( A \ (A') \) and \( B \ (B') \) are \( U \)-types in \( \Gamma \ (\Gamma') \) and \( \Gamma, x : T A \ (\Gamma', x' : T A') \), respectively.

The induction hypotheses give us
\[
\begin{align*}
\Gamma' \vdash A^* : \text{Eq} A A' \\
(\Gamma, x : T A) \vdash B^* : \text{Eq} B B' \\
\Gamma' \vdash f^* : \text{Ref} (\Pi A (\lambda x : T A. B))^* f f' \\
\Gamma' \vdash a^* : \text{Ref} A^* a a'
\end{align*}
\]

We may rewrite the type of \( f^* \) as
\[
\begin{align*}
\text{Ref} (\Pi A (\lambda x : T A. B))^* f f' \\
= \Pi x : T A \, \Pi x' : T A' \, \Pi x^* : \text{Ref} \, A^* \, x x'. \\
\text{Ref} ((\lambda x : T A. B)^* x x' x^*) (f x) (f' x') \\
= \Pi x : T A \, \Pi x' : T A' \, \Pi x^* : \Pi x. \text{Ref} \, A^* \, x x'. \\
\text{Ref} ((\lambda x : T A \, \lambda x' : T A') \, \lambda x'' : \text{Ref} \, A^* \, x x'. \text{Ref} \, B^* ((\lambda x' : T A') x x' x^*) (f x) (f' x') \\
= \Pi x : T A \, \Pi x' : T A' \, \Pi x^* : \Pi x. \text{Ref} \, A^* \, x x'. \text{Ref} \, B^* (f x) (f' x')
\end{align*}
\]

Working in \( \Gamma' \), we now apply \( f^* \) to \( a, a', a^* \) (which types are \( T A, T A', \text{Ref} \, A^* a a' \), respectively), in order to obtain
\[
f^* a a' a^* : \text{Ref} \, B^* (f x) (f' x') [a/x, a'/x', a^* / x^*].
\]
where we have used the hypotheses on $A^*$ and $B^*$ in validating application typing rule.

Since the sets of primed, starred, and vanilla variables are disjoint, and every variable in $f'$ is primed, while every variable in $f$ vanilla, we may rewrite the above as

$$f^* a a' a^* : \text{Rel } B^*[a/x, a'/x', a^*/x^*](f a)(f' a')$$

By the substitution lemma,

$$B^*[a/x, a'/x', a^*/x^*] = (B[a/x])^*$$

We may thus rewrite the above judgment as

$$\Gamma^* \vdash (fa)^* : \text{Rel } B[a/x]^*[fa](fa)'$$

as required.

**Pairing**

Given a derivation

$$
\begin{array}{lll}
\Gamma & \vdash A : T \otimes \\
\Gamma, x : T A & \vdash B : T \otimes & \Gamma \vdash a : TA & \Gamma \vdash b : TB[a/x] \\
\hline
\Gamma & \vdash (a, b) : T(\bigotimes A(\lambda x : T A. B))
\end{array}
$$

we have

$$
\begin{align*}
\Gamma^* & \vdash a^* : \text{Rel } A^* aa' \\
\Gamma^* & \vdash b^* : \text{Rel } B[a/x]^* bb'
\end{align*}
$$

We also have

$$
\begin{align*}
\text{Rel } (\bigotimes A(\lambda x : T A. B))^*[a, b](a', b') & = \text{Rel } ((\bigotimes A^*)^*(\lambda x : T A. B)^*)[a, b](a', b') \\
& = \Sigma a^* : \text{Rel } A^* a a'. \text{Rel } ((\lambda x : T A. B)^*[a a']^*)bb' \\
& = \Sigma a^* : \text{Rel } A^* a a'. \text{Rel } (B^*[a, a', a^*/x, x^*])bb' \\
& = \Sigma a^* : \text{Rel } A^* a a'. \text{Rel } B[a/x]^* bb'
\end{align*}
$$

Using the pairing rule, we see that $(a^*, b^*)$ can be given the type derived above. So by conversion, we find

$$\Gamma^* \vdash (a, b)^* : \text{Rel } (\bigotimes A(\lambda x : T A. B))^*[a, b](a, b)'$$

as required.

**Projections**

Given
we get, by induction hypothesis, that

$$\Gamma^* \vdash \rho^* : \text{Rel} (\Sigma \left( \lambda x : TA. B \right))$$

By the same computation as the previous case, we see that the type of $\rho^*$ above is convertible to

$$\Sigma \rho^* : \text{Rel} \left( \lambda p, p^* \vdash \pi_1 p^{\pi_1 p} \vdash \pi_2 p^{\pi_2 p} \right)$$

But then we have

$$\pi_1 p^*: \text{Rel} (\pi_1 p^{\pi_1 p}) \cdot \text{Rel} (\pi_2 p^{\pi_2 p})$$

The first judgment above already has the form required. As for the second, we use the substitution lemma to rewrite it as

$$(\pi_2 p^*)^*: \text{Rel} B[\pi_1 p/x]^{\pi_2 p} \cdot \pi_2 p^{\pi_2 p}$$

and this too obeys the form of $\text{(10)}$.

**Conversion** Suppose

\[
\begin{array}{c}
\Gamma \vdash A : T \\
\Gamma, x : TA \vdash B : T \\
\Gamma \vdash p : T (\Sigma A (\lambda x : TA. B)) \\
\Gamma \vdash \pi_1 p : TA \\
\Gamma \vdash \pi_2 p : TB[\pi_1 p/x]
\end{array}
\]

By induction hypothesis, we have

$$\Gamma^* \vdash \rho^* : \text{Rel} A^* M M'$$

The fact that $A = B$, entails, for deep typographical reasons, that $A' = B'$. Hence by conversion, we have that $M : B$ as well as $M' : B'$. But we also have that $B : U$, so that $B^* : \text{Rel} \otimes B B'$, or equivalently $B^* : \text{Eq} B B'$.

These facts yield that $\text{Rel} B^* M M' : *$.

By Proposition $\text{(11)}$ $\text{Rel} A^* M M' = \text{Rel} B^* M M'$.

$$\Gamma^* \vdash M^*: \text{Rel} B^* M M'$$
5 Higher dimensions

The theorem in the previous section can be extended to higher dimensions. For example, for the groupoid level, we can write an IIRD defining terms

$$\text{Eq}_2 : \Pi AB : U. \text{Eq}_{AB} \rightarrow \text{Eq}_{AB} \rightarrow *$$

$$\text{Rel}_2 : \Pi AB : U. \text{Eq}_{AB} \rightarrow \text{Eq}_{AB} \rightarrow *$$

We can follow the same steps as before, and prove extensionality of the 1-dimensional $\lambda U \equiv$ terms as well.

In the next dimension, we would define terms

$$\text{Eq}_3 : \Pi AB : U. \text{Eq}_{AB} \rightarrow \text{Eq}_{AB} \rightarrow \text{Eq}_{AB} \rightarrow *$$

$$\text{Rel}_3 : \Pi AB : U. \text{Eq}_{AB} \rightarrow \text{Eq}_{AB} \rightarrow \text{Eq}_{AB} \rightarrow *$$

It is clear that this method could be continued indefinitely. Once we build a countable sequence of such IIRD types, we get a type theory in which the extensionality of every term is witnessed by a higher-dimensional instance of that term.

It is easier to look at the pattern of the definitions required to ascend extensionality from one dimension to the next. We can then cover all dimensions at once by making this pattern part of our universe.

On the next page, we give a double IIRD in which the equivalence and relation types are fully internalized into the universe. The notation

$$\text{Φ}_x : A$$

$$\text{Ω}_x : A$$

is used there to denote the terms

$$\text{Φ}_A(\lambda x : TA)$$

$$\text{Ω}_A(\lambda x : TA)$$

6 Future work

In order to reason about extensional identity type within the system itself, it could feel good to internalize the above theorem into the language of type theory. This will require reflecting not only the type level but also the syntax of terms. Furthermore, one would need to simultaneously treat symmetry and transitivity, together with the interaction between them and everything else.
Inductive $U : * :=$

$\mathord{\text{Eq}} : U \\
\mathord{\text{ tt : } \Pi A : U. \text{ (T } A \rightarrow U \text{) } \rightarrow U} \\
\mathord{\text{ ff : } \Pi A : U. \text{ (T } A \rightarrow U \text{) } \rightarrow U} \\
\mathord{\text{ e : } U \rightarrow U \rightarrow U} \\
\mathord{\text{ n : } \Pi \{AB \} : U. \text{ T }[\mathord{\text{ n AB }]} \rightarrow \text{ TA } \rightarrow \text{ TB } \rightarrow U}$

with $T : U \rightarrow * :=$

$T(\mathord{\text{ tt }}) = U \\
T(\mathord{\text{ ff AB }]) = \Pi a : \text{ TA}. \text{ T}[B a] \\
T(\mathord{\text{ n AB }]} = \Sigma a : \text{ TA}. \text{ T}[B a] \\
T(\mathord{\text{ e AB }]} = [\text{ Inductive } \text{ Eq : U } \rightarrow U \rightarrow * ]$

$\mathord{\text{ r ( n ) : Eq n n }} \\
\mathord{\text{ n t : } \Pi \{A \}\{A'\}} \Pi A^* : \text{ Eq AA'} \\
\Pi\{B\}\{B'\} \Pi B^* : (\Pi a a' : \text{ Eq}(B a)(B' a')). \\
\text{ Eq}(\mathord{\text{ n AB }]}(\mathord{\text{ n AB }]}A'B') \\
\mathord{\text{ n f : } \Pi \{A\}\{A'\}} \Pi A^* : \text{ Eq AA'} \\
\Pi\{B\}\{B'\} \Pi B^* : (\Pi a a' : \text{ Eq}(B a)(B' a')). \\
\text{ Eq}(\mathord{\text{ n AB }]}(\mathord{\text{ n AB }]}A'B') \\
\mathord{\text{ n e : } \Pi \{AA'\} A^* \{BB'\} B^*}. \text{ Eq}(\mathord{\text{ n AB }]}(\mathord{\text{ n AB }]}A'B') \\
\mathord{\text{ n f : } \Pi \{AA'\} A^* \{BB'\} B^*. \text{ Eq}(\mathord{\text{ n e AB }]})(\mathord{\text{ n e AB }]}a b)'}$

with $\text{ Rel } \{AB : U\} : \text{ Eq AB } \rightarrow \text{ TA } \rightarrow \text{ TB } \rightarrow U$

$\text{ Rel } (\mathord{\text{ n AB }]} AB = \mathord{\text{ n AB }} \\
\text{ Rel } (\mathord{\text{ n f AB }]} f f' = \mathord{\text{ n x A t x : A' n x : A' n x :}} \text{ Rel } A^* x x'. \\
\text{ Rel } (B^* x x' x')(f x)(f' x') \\
\text{ Rel } (\mathord{\text{ n f AB }]} p p' = \mathord{\text{ n x :}} \text{ Rel } A^*(\pi_1 p)(\pi_1 p'). \\
\text{ Rel } (B^*(\pi_1 p)(\pi_1 p')x')(\pi_2 p)(\pi_2 p') \\
\text{ Rel } (\mathord{\text{ n f AB }]} (\pi_1 p)(\pi_1 p') ee' = \mathord{\text{ n a a' t b b'}} \\
\text{ Rel } (\mathord{\text{ n f AB }]} (\pi_1 p)(\pi_1 p') ee' = \mathord{\text{ n a a' t b b'}} \gamma' = \\
\mathord{\text{ n e a a' t b b'}} \gamma' \\
\text{ T } (\mathord{\text{ n e AB }]} = \text{ T } (\text{ Rel e AB })$
