Abstract
The paper studies a novel adaptive identifier proposed in IFAC World Congress 2020 for nonlinear time-delay systems composed of linear, Lipschitz and non-Lipschitz components. To begin with, an identifier is designed for uncertain systems with a priori known delay values, and then it is generalized for systems with unknown delay values. The algorithm ensures the asymptotic parameter estimation and state observation by using gradient algorithms. The unknown delays and plant parameters are estimated by using a special equivalent extension of the plant equation. The algorithms stability is presented by solvability of linear matrix inequalities. Simulation results are invoked to support the developed identifier design and to illustrate the efficiency of the proposed synthesis procedure.

Key words
Synchronization, estimation, nonlinear systems, time-delays, adaptive.

1 Introduction
Since the mid-1980s, the definition of synchronization has been used as the coincidence of the coordinates of subsystem state vectors [Fujisaka and Yamada (1983)]. This definition became especially popular after the publication of an article by L. Pecora and T. Carroll on the control of synchronization of chaotic systems [Pecora and Carroll(1990)]. Adaptive synchronization of free-delay physical systems is studied in [Fradkov (2007)].

The investigation focuses on adaptive/on-line identification of unknown time-invariant plant parameters. The existing literature suggests many design methods for plants with lumped model and known structure, see, e.g. [Landau(1979); Goodwin and Sin(1984); Astrom and Wittenmark(1989); Narendra and Annaswamy(1989); Sastry and Bodson(1989); Ioannou and Sun(1995); Ljung(1999)]. These methods demonstrate acceptable robustness in the presence of small input and output disturbances or small perturbations of model parameters. Due to this, the methods have found practical applications in electrical vehicle application [Flah et. al.(2014)], robotics [Farza et al.(2009)], chemical industry [Ekramian et al.(2013)], etc. However, there are only few results applicable to synthesis of plants with time-delays, see, e.g. [Nakagiri and Yamamoto(1995); Verduyn(2001); Orlov et al.(2001); Belkoura and Orlov(2002); Orlov et al.(2002); Orlov et al.(2003); Orlov et al.(2009)].

In [Nakagiri and Yamamoto(1995); Verduyn(2001)] the identification of time-delay systems demonstrated complexity of the problem, particularly, the identifiability of a delay system was shown to place a restrictive condition on the structure of the system. This condition was defined through the characteristic matrix of the functional differential equation of the plant whereas no indication was given on how to attain this condition using some accessible inputs.

In [Orlov et al.(2001); Belkoura and Orlov(2002); Orlov et al.(2002); Orlov et al.(2003); Orlov et al.(2009)], the adaptive identifiers were developed step by step, for systems with the complete state information and for single input single output (SISO) linear time delay systems, given in the canonical form of a differential equation of an arbitrary order. Necessary and sufficient conditions for a linear delay system to be identifiable have been given in terms of weak controllability property and nonsmooth input signals. In [Orlov et al.(2009)] the proposed results were experimentally confirmed in an application to a port-fuel-injected internal combustion engine.

Recently, [Furtat and Orlov (2020)] addressed the identification of time delay systems in the nonlinear set-
ting. The present investigation continues that of [Furtat and Orlov (2020)] to collect both theoretical and numerical studies yielding a model-synchronization-based approach to identification of parameters of nonlinear systems with unknown time delays. The proposed model mimics the underlying plant with model parameters which are dynamically adjusted in such a manner to ensure their convergence to the unknown plant parameters. The resulting closed-loop system utilizes the entire state measurements and it can be viewed as an on-line identifier of the nonlinear time delay system in question.

The rest of the paper is outlined as follows. The problem statement is given in Section 2. In Sections 3 and 4, two algorithms are developed side by side for a priori known and unknown delays, accompanied with the convergence conditions of the proposed algorithms, given in terms of specific LMIs feasibility. In Section 5, the capability of the proposed synthesis is illustrated in a simulation study to additionally support the analytical results. Finally, Section 7 collects some conclusions.

Notations. Throughout the paper, the superscript $T$ stands for the matrix transposition; $\mathbb{R}^n$ denotes the $n$ dimensional Euclidean space with vector norm $| \cdot |$; $\mathbb{R}^{n \times m}$ is the set of all $n \times m$ real matrices; the notation $P > 0$ for $P \in \mathbb{R}^{n \times n}$ means that $P$ is symmetric and positive definite; $I$ is the identity matrix of an appropriate dimension; $\text{diag}\{\}$ is used for a block diagonal matrix.

## 2 Problem Formulation

Consider a plant model in the form

$$
\dot{x}(t) = \sum_{i=0}^{k} \left[ A_i x(t - \tau_i) + D_i \varphi(x(t - \tau_i)) \right] + G_i \psi(y(t - \tau_i)) + B_i u(t - \tau_i),
$$

$$
y(t) = C x(t),
$$

where $t \geq 0$, $x(t) \in \mathbb{R}^n$ is the state vector, $u(t) \in \mathbb{R}$ is the control input which is assumed to be piece-wise continuous bounded function, $y(t) \in \mathbb{R}$ is the output signal, available for the measurement. For certainty, the time-delay values $\tau_i$ are ordered as follows $0 = \tau_0 < \tau_1 < \ldots < \tau_k$.

The function $\varphi(x) \in \mathbb{R}^l$ is globally Lipschitz continuous with an a priori known Lipschitz constant $L$. The nonlinear function $\psi(y(t)) \in \mathbb{R}^m$ is a piece-wise continuous. The well-posedness of system (1) is thus ensured in the open-loop. Along with the above functions, the matrix $C \in \mathbb{R}^{1 \times n}$ is also known a priori whereas the matrices $A_i \in \mathbb{R}^{n \times n}, D_i \in \mathbb{R}^{n \times l}, G_i \in \mathbb{R}^{n \times m}$ and $B_i \in \mathbb{R}^m$ are unknown. Due to the duality of control synthesis and observer design, the measured output is predetermined with no measurement delays to ensure the identifiability of uncertain matrix parameters (see Assumption 4). Since some matrices might be zero, without loss of generality system (1) has been assumed to possess the same state and input delays.

The delay-free model (1), formally coming with $\tau_1 = \ldots = \tau_k = 0$, is considered for feedback control and for observation of $x$ in [Farza et al.(2009); Ekramian et al.(2013)]. In these papers it is noted that such free delay model can describe a number of technical systems and technological processes. For instance, the estimation of the state and kinetic parameters is addressed in [Farza et al.(2009)] for a bioreactor whereas in [Farza et al.(2009)], the estimation is investigated for a single-link manipulator with revolute joints actuator. In [Kumar et al.(2019)] the model of chemical and biochemical reactors have input and state delays which arise due to delays in the reception and transmission of data and technological cycles. While controlling electrical equipment, delays are caused by the remote control via digital communication channels. However, for model with delays (1) the identification problem has not been addressed so far.

The following technical assumptions are made throughout.

**Assumption 1.** System (1) is a BIBO (bounded input bounded output) system in the sense that while being driven by a bounded input, the system generates a bounded solution regardless of wherever it is initialized.

**Assumption 2.** The input signal $u(t)$ is uniformly bounded and periodic, and persistently excites system (1) in the sense that there exist constants $C > 0$ and $\alpha > 0$ such that

$$
\int_{t_0}^{t+C} \Phi(s) \Phi(s)^T ds \geq \alpha I
$$

with $\Phi(t) = \text{col}\{x(t-\tau_0), \ldots, x(t-\tau_k), \varphi(t-\tau_0), \ldots, \varphi(t-\tau_k), \psi(t-\tau_0), \ldots, \psi(t-\tau_k), u(t-\tau_0), \ldots, u(t-\tau_k)\}$ computed along an arbitrary system solutions $x(t)$.

**Assumption 3.** The following matching conditions hold

$$
A_i = A_i^0 + T_0 \kappa_i^A, \quad D_i = D_i^0 + T_0 \kappa_i^D,
$$

$$
G_i = G_i^0 + T_0 \kappa_i^G, \quad B_i = B_i^0 + T_0 \kappa_i^B, \quad i = 0, \ldots, k,
$$

where $A_i^0, D_i^0, G_i^0, B_i^0$, and $T_0 \in \mathbb{R}^n$ are known and $CT_0 \neq 0$, whereas $\kappa_i^A \in \mathbb{R}^{1 \times n}, \kappa_i^D \in \mathbb{R}^{1 \times l}, \kappa_i^G \in \mathbb{R}^{n \times m}$, and $\kappa_i^B \in \mathbb{R}$ are unknown.

**Assumption 4.** System (1) is identifiable in the sense that there exists a persistently exciting input $u(t)$ such that the unknown parameters in (1) are uniquely determined from the measured output $y(t)$ [Orlov et al.(2003)].

**Assumption 5.** System (1) is locally observable in the sense that the difference $\Delta z(t)$ of arbitrary solutions $x(t), \hat{x}(t)$ of (1) asymptotically escapes $\lim_{t \to \infty} \Delta z(t) = 0$ to zero provided that these solutions generate the same output $C x(t) = C \hat{x}(t)$ for all $t \geq 0$.

The above assumptions are made for technical reasons. Assumption 1 is well-recognized from the linear theory to be imposed on a system for its on-line identification in open-loop [Orlov et al.(2002)]. Assumption 2 is an extension of the well-known Persistency-of-Excitation (PE) condition (see definition of PE condition in [Shimkin and Feuer(1987); Mareels ... ]
where $k_i^\Delta(t), \hat{k}_i^\Delta(t), \hat{k}_i^G(t), \hat{k}_i^B(t)$, and $\hat{x}(t)$ are dynamic estimates of the nominal values $k_i^A, k_i^D, k_i^G, k_i^B$, and $x(t)$ accordingly. 

The objective is to design an identification algorithm that ensures

$$
\lim_{t \to \infty} \Delta k_i^A(t) = 0, \quad \lim_{t \to \infty} \Delta k_i^D(t) = 0,
\lim_{t \to \infty} \Delta k_i^G(t) = 0, \quad \lim_{t \to \infty} \Delta k_i^B(t) = 0, \quad \lim_{t \to \infty} \varepsilon(t) = 0.
$$

In what follows, such an identification algorithm is developed for the nonlinear time-delay system in question.

### 3 Adaptive identifier design under a priori known delay values

Consider a plant model

$$
\dot{x}(t) = \sum_{i=0}^k \left[ A_i^0 \dot{x}(t - \tau_i) + D_i^0 \varphi(\dot{x}(t - \tau_i)) + C_i \psi(y(t - \tau_i)) + B_i u(t - \tau_i) - Y_i \varepsilon(t) \right],
$$

of the same structure as that of (1) with Hurwitz matrices $Y_i \in \mathbb{R}^{n_x \times n}$ at the designer disposition. Let the model parameters be updated as $\dot{k}_i^A(t)^T = -\Gamma_i^A e(t) \dot{x}(t - \tau_i), \hat{k}_i^D(t)^T = -\Gamma_i^D e(t) \varphi(\dot{x}(t - \tau_i)), \hat{k}_i^G(t)^T = \Gamma_i^G e(t) \varphi(y(t - \tau_i)), \hat{k}_i^B(t)^T = -\Gamma_i^B e(t) u(t - \tau_i)$. The parameter errors are governed by

$$
\dot{\varepsilon}(t) = \sum_{i=0}^k \left[ A_i \varepsilon(t - \tau_i) + D_i \varphi(x(t - \tau_i)) - \varphi(\dot{x}(t - \tau_i)) - Y_i \varepsilon(t) \right] + T_0 \sum_{i=0}^k \left[ \Delta k_i^A(t) \dot{x}(t - \tau_i) + \Delta k_i^D(t) \varphi(\dot{x}(t - \tau_i)) + \Delta k_i^G(t) \psi(y(t - \tau_i)) + \Delta k_i^B(t) u(t - \tau_i) \right],
$$

$$
e(t) = C \varepsilon(t).
$$
The result, stated below, relies on the notation

\[
\Psi_{11} = A_k^T P + PA_0 - Y_0 + \sum_{i=0}^k S_i, \\
\Psi_{11} P(A_k - Y_k) \quad P(A_k - Y_k) \\
* - S_i - Y_i \ldots 0 \\
* \ldots \ldots \ldots \ldots \ldots \ldots \\
* \ldots \ldots \ldots \ldots \ldots \ldots \\
PD_0 PD_1 \ldots PD_k \\
* 0 \ldots 0 \\
* \ldots \ldots \ldots \ldots \ldots \ldots \\
* \ldots \ldots \ldots \ldots \ldots \ldots \\
* \ldots \ldots \ldots \ldots \ldots \ldots \\
\Psi = \begin{bmatrix} \Psi_{11} + L^2 I & \Psi_{12} \\ * & -I \end{bmatrix}
\] (8)

Here the notation "∗" means a symmetric block of a symmetric matrix.

**Theorem 1.** Let the delay values \( \tau_j, j = 1, \ldots, k \) be known a priori, and let Assumptions 1–5 hold. Moreover, let there exist matrices \( P = P^T > 0, S_i > 0 \), \( i = 0, \ldots, k \) such that the relations

\[
\Psi < 0 \quad \text{and} \quad PT_0 = C^T
\] (9)

hold true. Then the over-all error system (6), (7) is asymptotically stable so that the above objective (4) is achieved with identifier (5), updated according to (7).

The proof of Theorem 1 is considered in [Furtat and Orlov (2020)].

## 4 Case of unknown time-delays

In the present section, the number \( k \) of time-delays \( \tau_i \), \( i = 1, \ldots, k \) of the plant dynamics (1) are no longer assumed to be known a priori. The identifier design in such a framework calls for another interpretation of equation (1). To formally apply the developed identifier let us introduce the following notations

\[
k \geq k, \quad 0 = \tau_0 < \tau_1 < \ldots < \tau_k, \\
A_i \in \mathbb{R}^{n \times n}, D_i \in \mathbb{R}^{n \times l}, \\
G_i \in \mathbb{R}^{m \times n}, B_i \in \mathbb{R}^m, \quad i = 1, \ldots, k, \\
\Xi = \{\tau_1, \ldots, \tau_k\}, \\
\Xi = \{\tau_1, \ldots, \tau_k\}, \\
\Lambda = \{A_i, D_i, G_i, B_i : i = 1, \ldots, k\}, \\
\Lambda = \{A_i, D_i, G_i, B_i : i = 1, \ldots, k\},
\] (10)

and impose the following assumptions.

**Assumption 6.** The values of \( \tilde{k} \) and \( \tilde{\tau} \), \( i = 1, \ldots, \tilde{k} \) are known a priori whereas the matrices \( A_i, D_i, G_i, B_i, i = 1, \ldots, \tilde{k} \) are unknown.

**Assumption 7.** The implications \( \Xi \subseteq \Xi' \) and \( \Lambda \subseteq \Lambda' \) are in force and the sets \( \Xi \setminus \Xi \) and \( \Lambda \setminus \Lambda \) contain zero elements.

The above assumptions presume that unknown plant delays belong to an \textit{a priori} known finite set as it happens, e.g., in computer networks where transmission delays are commensurate a specific precision. Thus, the identification of unknown delay values is reduced to identifying fictitious delay values, which are associated with zero matrix multipliers to be identified along with other nonzero parameter values. Indeed, using notations (10) and Assumptions 6, 7, rewrite plant equation (1) in the form

\[
\dot{x}(t) = \sum_{i=0}^\tilde{k} [A_i x(t - \tau_i) + D_i \varphi(x(t - \tau_i)) + G_i \psi(y(t - \tau_i)) + B_i u(t - \tau_i)], \\
y(t) = C x(t).
\] (11)

It is worth noticing that model (11) has been obtained based on the modifications of Assumptions 2 and 3, given below.

**Assumption 8.** The input signal \( u(t) \) is uniformly bounded and periodic, and persistently excites system (11) in the sense that there exist constants \( C > 0 \) and \( \alpha > 0 \) such that \( f_t^{t+C} \Phi(s) \Psi(s)^T ds \geq \alpha t \) with \( \Phi(t) = \text{col}(x(t - \tau_0), \ldots, x(t - \tau_k), \varphi(t - \tau_0), \ldots, \varphi(t - \tau_k), \psi(t - \tau_0), \ldots, \psi(t - \tau_k), u(t - \tau_0), \ldots, u(t - \tau_k)) \), computed along an arbitrary system solution \( x(t) \).

**Assumption 9.** The following matching conditions hold

\[
A_i = A_i^0 + T_0 \kappa_i^A, \quad D_i = D_i^0 + T_0 \kappa_i^D, \quad G_i = G_i^0 + T_0 \kappa_i^G, \\
B_i = B_i^0 + T_0 \kappa_i^B, \quad i = 0, \ldots, k, \quad \text{where} \quad A_i^0, D_i^0, G_i^0, B_i^0, \\
T_0 \in \mathbb{R}^n \text{ are known matrices and vectors, and } C T_0 \neq 0, \\
\text{whereas} \quad \kappa_i^A \in \mathbb{R}^{n \times n}, \quad \kappa_i^D \in \mathbb{R}^{1 \times n}, \quad \kappa_i^G \in \mathbb{R}^{1 \times m}, \quad \text{and} \quad \kappa_i^B \in \mathbb{R}^m.
\]

The basic idea behind the representation of model (1) in form (11) is as follows. If \( x(t - \tilde{\tau}) = x(t - \tau(j)) \) for some \( l \in \{i, \ldots, \tilde{k}\} \) and \( j \in \{i, \ldots, \tilde{k}\} \), then \( A_l = A_j \). Otherwise, \( x(t - \tilde{\tau}) \neq x(t - \tau(j)) \) for any \( l \in \{i, \ldots, \tilde{k}\} \) and \( j \in \{i, \ldots, \tilde{k}\} \), and \( A_l = 0 \). Similar comments are also in order for other terms in (11). Thus, identifying nonzero matrices among of \( A_i, D_i, G_i, B_i, i = 1, \ldots, \tilde{k} \) yields corresponding (non-fictitious) time-delays.

Let us now consider the identifier in the form

\[
\dot{x}(t) = \sum_{i=0}^\tilde{k} [A_i^0 \dot{x}(t - \tau_i) + D_i^0 \varphi(\dot{x}(t - \tau_i)) + G_i^0 \psi(y(t - \tau_i)) + B_i^0 u(t - \tau_i)] + T_0 \sum_{i=0}^\tilde{k} \kappa_i^A(t) \dot{x}(t - \tau_i) + \kappa_i^D(t) \varphi(\dot{x}(t - \tau_i)) + \kappa_i^G(t) \psi(y(t - \tau_i)) + \kappa_i^B(t) u(t - \tau_i) - Y_\varepsilon(t - \tau_i), \]

\[
\dot{y}(t) = C \dot{x}(t).
\] (12)

Computing the time derivative of \( \varepsilon(t) = x(t) - \dot{x}(t) \) along the trajectories (11) and (12), one obtains
\[ \dot{e}(t) = \sum_{i=0}^{k} \left[ \bar{A}_i e(t-\tau_i) - Y_i e(t-\tau_i) \right] + \sum_{i=0}^{k} \bar{D}_i [\varphi(x(t-\tau_i) - \varphi(\hat{x}(t-\tau_i))] \\
+ T_0 \sum_{i=0}^{k} \left[ \Delta \kappa_i^A(t) \dot{x}(t-\tau_i) \\
+ \Delta \kappa_i^B(t) \dot{y}(t-\tau_i) \right] + \Delta \kappa_i^C(t) \psi(y(t-\tau_i)) + \Delta \kappa_i^D(t) u(t-\tau_i) \right], \\
e(t) = C e(t). \]

According to model (13), the corresponding matrices in (4) are represented as

\[ \Psi_{11} = A_0^T P + P A_0 - Y_0 + \sum_{i=0}^{k} S_i, \]
\[ \Psi_{11} = \begin{bmatrix} P(A_1 - Y_1) & \ldots & P(A_k - Y_k) \\
* & -S_1 - Y_1 & \ldots & 0 \\
* & \vdots & \ddots & \vdots \\
* & \vdots & \ldots & -S_k - Y_k \end{bmatrix}, \]
\[ \Psi_{12} = \begin{bmatrix} P \bar{D}_0 & P \bar{D}_1 & \ldots & P \bar{D}_k \\
* & 0 & \ldots & 0 \\
* & \vdots & \ddots & \vdots \\
* & \vdots & \ldots & 0 \end{bmatrix}. \]

The structure of \( \Psi \) is the same as in (4).

**Theorem 2.** Let Assumptions 1, 4–9 hold and let there exist matrices \( P = P^T > 0, S_i > 0, i = 1, \ldots, k \) such that

\[ \Psi < 0 \text{ and } PT_0 = C^T. \] (14)

Then the identification algorithms

\[ \begin{align*}
\dot{k}_i^A(t)^T &= \Gamma_i^A \dot{x}(t-\tau_i) e(t), \\
\dot{k}_i^B(t)^T &= \Gamma_i^B \dot{y}(y(t-\tau_i)) e(t), \\
\dot{k}_i^C(t)^T &= \Gamma_i^C \dot{y}(y(t-\tau_i)) e(t), \\
\dot{k}_i^D(t)^T &= \Gamma_i^D u(t-\tau_i) e(t)
\end{align*} \] (15)

ensure objective (4), where \( \Gamma_i^A, \Gamma_i^B, \) and \( \Gamma_i^C \) are positive definite matrices with appropriate dimensions and \( \Gamma_i^B > 0. \)

The proof of Theorem 2 is considered in [Furtat and Orlov (2020)].

**Remark 1.** Model (11) has a rough approximation relatively to value of \( \bar{k} \). Thus, an overestimated number of estimated parameters is in play, and hence, a larger transient time is obtained. However, using the model

\[ \dot{x}(t) = \sum_{i=0}^{k_1} \bar{A}_i x(t-\tau_i) + \sum_{i=0}^{k_2} \bar{D}_i \varphi(x(t-\tau_i)) \\
+ \sum_{i=0}^{k_3} \bar{G}_i \psi(y(t-\tau_i)) + \sum_{i=0}^{k_4} \bar{B}_i u(t-\tau_i), \\
y(t) = C x(t). \] (16)

with smaller numbers \( \bar{k}_j < k, j = 1, \ldots, 4 \) of estimated parameters allows one to reduce the number of adjustable parameters, thereby reducing the transient time of estimation of unknown parameters. It is clear that the algorithm for model (16) remains similar to the algorithm for model (11).

**5 Study of Adaptive Identifier**

Let model (1) be described as

\[ \dot{x}(t) = \begin{bmatrix} 0 & 1 \\
0 & 0 \end{bmatrix} x(t) + \begin{bmatrix} 0 & 0 \\
1 & 0 \end{bmatrix} \varphi(x(t-\tau_2)) \]
\[+ \begin{bmatrix} 0 & 0 \\
0 & 0 \end{bmatrix} \psi(y(t)) + \begin{bmatrix} 0 & 0 \\
1 & 0 \end{bmatrix} u(t), \]
\[ y(t) = [1 \ 3] x(t), \]

where \( x(t) = \text{col}\{x_1(t), x_2(t)\} \), the nonlinearities \( \varphi(x) = \text{col}\{x_1^2, x_2^2\} \) and \( \psi(y) = y^2 \) are known. Only output \( y(t) \) and input \( u(t) \) are available for measurement. Assume that the value set of the system delays is \( a \text{ priori} \) known, but it is unknown which delay corresponds to each component \( x(t), \varphi(x(t)), \psi(y(t)), \) and \( u(t) \).

Therefore, according to model (11), rewrite (17) in the form

\[ \dot{x}(t) = \sum_{i=0}^{3} \left( \begin{bmatrix} 0 & 1 \\
0 & 0 \end{bmatrix} x(t-\tau_i) \right) \\
+ \begin{bmatrix} 0 & 0 \\
0 & 0 \end{bmatrix} \varphi(x(t-\tau_i)) \]
\[+ \begin{bmatrix} 0 & 0 \\
1 & 0 \end{bmatrix} \psi(y(t-\tau_i)) + \begin{bmatrix} 0 & 0 \\
1 & 0 \end{bmatrix} u(t-\tau_1), \] (18)

where \( \tau_0 = 0, \tau_1 = \tau_2 = \tau_3 = 0 \) due to known values of delays. Thus, model (18) contains any combination of delays in (17).

Let \( u(t) = \text{sin}(2.3t) + \text{sin}(10t) + \text{sin}(20.2t) + \text{sin}(35.7t) + \text{sin}(51.9t) + P_G \) \( P_G \) is the function describing pulse generator with amplitude 1, period 1 s and pulse width 0.5%, \( \tau_1 = 1, \tau_2 = 1.7, \) and \( \tau_3 = 2.3 \) in (17), \( \Gamma_i^A = 400 I, \Gamma_i^B = 400 I, \Gamma_i^C = 400 I, \) and \( \Gamma_i^D = 400, i = 0, \ldots, 3 \) in (15). The simulations show that Assumption 8 holds for \( C \geq 10^3 \) and \( \alpha \leq 10^{-4} \). Choosing \( \bar{A}_i = \begin{bmatrix} 0 \ 0 \\
0 \ 0 \end{bmatrix}, \bar{A}_j = \begin{bmatrix} 0 \ 0 \\
0 \ 0 \end{bmatrix}, j = 1, 2, 3, \)
\[ \bar{D}_i = \begin{bmatrix} 0 \ 0 \\
0 \ 0 \end{bmatrix}, \bar{G}_i = \begin{bmatrix} 0 \ 0 \\
0 \ 0 \end{bmatrix}, i = 0, \ldots, 3, \]
\[ T_0 = \begin{bmatrix} 0 & 1 \end{bmatrix} \]
Assumption 9 holds. Denote \( \kappa_i^A(t) = [\bar{a}_1(t), \bar{a}_2(t)], \kappa_i^B(t) = [\bar{d}_1(t), \bar{d}_2(t)], \kappa_i^C(t) = \bar{g}_i(t), \) and \( \kappa_i^D(t) = \bar{b}_i(t), \) where \( \bar{a}_1(t), \bar{a}_2(t), \bar{d}_1(t), \bar{d}_2(t), \bar{g}_i(t), \) and \( \bar{b}_i(t) \) are the estimates of \( \bar{a}_1, \bar{a}_2, \bar{d}_1, \bar{d}_2, \bar{g}_i, \) and \( \bar{b}_i(t) \) accordingly. In Figures 1–5 the transients of these estimates are presented.
Figure 3. The transients of $\hat{d}_{i1}(t)$, $\hat{d}_{i2}(t)$, $i = 0, ..., 3$, where $d_{21} = -0.5$, $d_{22} = -0.8$, $d_{01} = d_{02} = d_{11} = d_{12} = d_{31} = d_{32} = 0$.

Figure 4. The transients of $\hat{g}_i(t)$, $i = 0, ..., 3$, where $g_0 = -2$, $g_1 = g_2 = g_3 = 0$.

Figure 5. The transients of $\hat{b}_i(t)$, $i = 0, ..., 3$, where $b_0 = 1$, $b_1 = b_2 = 0$, and $b_3 = -1$.

Figure 1. The transients of $\varepsilon(t) = col\{\varepsilon_1(t), \varepsilon_2(t)\}$. 
Figure 2. The transients of \( \hat{a}_{i1}(t) \), \( \hat{a}_{i2}(t) \), \( i = 0, \ldots, 3 \), where
\[
\begin{align*}
    a_{01} &= -2, & a_{02} &= -4, & a_{11} &= -0.1, & a_{12} &= 0.2, & a_{21} &= a_{22} = a_{31} = a_{32} &= 0.
\end{align*}
\]

6 Acknowledgment

The results of Sections 3,4 were developed under support of RSF (grant 18-79-10104) in IPME RAS. The results of Section 5 were developed under support of grant of the Government of Russian Federation (Grant 08-08).

7 Conclusions

In the paper we study a novel adaptive identifier proposed in [Furtat and Orlov (2020)] for nonlinear systems composed of linear part, Lipschitz and non-Lipschitz nonlinearities. The case of known time-delay values and that of unknown delays are addressed side by side. In contrast to the existing literature, SISO time delay systems are considered in the general form rather than in the canonical form only. The identifiability and observability properties are coupled to the persistent excitation of the plant model to ensure the asymptotic convergence of estimated parameters to their real values by using the gradient algorithm. The stability analysis is given in terms of the feasibility of certain linear matrix inequalities, relying on input and output matrices. The numerical simulations confirm theoretical results and illustrate efficiency of the proposed algorithm for on-line simultaneous estimation of a large number of unknown parameters, including 2 state components and 24 parameters.
