Abstract

Background: Although it is known that several factors may influence the access to specialized care, the factors related to the maintenance of a link with Primary Care by patients who accessed Specialized Mental Health Services (SMHS) remain unknown. The aim of this study was to evaluate the determinants of timely access to SMHS and maintenance of a link with Primary Care.

Methods: This is a cross-sectional study, conducted with 341 users of SMHS at outpatient and community level in a medium-sized city in Brazil. Associations between the outcomes and the other variables were explored with the use of Poisson regression models with robust variance estimators.

Results: Among the factors associated with the study outcomes, those related to the organization of services and the movement between them were noteworthy. Patients referred by Primary Care were less likely to access specialized services in a timely manner (RR: 0.61; 95% CI: 0.40, 0.93). However, the referral of cases by Primary Care (RR: 1.38; 95% CI: 1.06, 1.79) and follow-up with visits by Community Health Agents (RR: 1.26; 95% CI: 1.04, 1.53) appeared to favor maintenance of the patient-Primary Care link.

Conclusion: This study reinforces the idea that integration between Primary Care and SMHS should be strengthened, both to reduce waiting times for between-service referrals and benefit continuity of care.

Background

The study of pathways to mental health care is an important means of understanding how health systems work and which parts of the pathways that need to be targeted by initiatives to support timely access to specialized programs. A systematic review of pathways to mental health care in 23 countries [1] pointed out that considerable variations of pathways to mental healthcare across different countries still exist and the role of Primary Care doctors and social networks still represent an unsolved issue.

Data obtained by pathways to mental health care studies may play a crucial role in formulating mental health policies and in the organization of psychiatric services [2]. However, this type of study is still emerging in low and middle-income countries, especially in Latin America. While studies are found in Cuba and Mexico [3], a systematic review conducted in Brazil [4] indicated that few quantitative studies have addressed specific stages of pathways to mental health care in the country.

It is estimated that 6.9 million Brazilians (3.3%) present severe and persistent mental health disorders requiring intensive and continuous mental health care [5], while an additional 30.2 million (14.5%) present mild or moderate mental health disorders requiring occasional treatment in specialized services [6]. Despite that, as observed in other countries, there is still an important treatment gap, with the lack of trained professionals to provide mental health care in Primary Care and the low integration with the mental health network being the main challenges [7].
A study conducted in the largest of Brazil’s metropolitan areas found that in the last 12 months, just one in five adults with any psychiatric disorder used a mental health service, and only one in ten consulted a psychiatrist [8]. This study also showed that specialized services delivered more appointments than Primary Care and that a greater proportion of individuals received a minimum threshold of adequacy in specialized care as compared to Primary Care.

Although access to specialized services is one of the main components of the study of pathways to mental health care, another aspect that needs to be explored in greater depth concerns to the continuity of the patient's link with Primary Care. Studies have shown that after accessing specialized services, many patients lose their link with Primary Care [9,10], which can lead to neglect of physical health conditions and poor clinical outcomes [11].

It is known that several factors may influence the access to specialized care, such as: age, gender, ethnicity, beliefs about mental illness, family involvement in help seeking, geographical characteristics and aspects related to the arrangement of the systems of care (e.g. referral route and service structure) [12]. On the other hand, the factors related to the maintenance of a link with Primary Care by users who accessed specialized mental health services remain unknown.

In the face of that, the aim of the current study is to fill this gap in the literature and evaluate the determinants both of timely access to Specialized Mental Health Services and the maintenance of a link with Primary Care in a medium-sized city in the state of São Paulo, Brazil.

### Methods

**Study design and Sample**

We conducted a cross-sectional study from August to November 2019 with users from three Outpatient Mental Health Care Services in the municipality of Itatiba, located approximately 80 km from the state capital of São Paulo. This city is part of the Metropolitan Region of Campinas, and according to the last census, the estimated population in 2019 was 120,858 inhabitants [13]. The city has 19 Primary Care services, and in addition to hospital and emergency services, there are three Outpatient Services providing mental health care to the population. These services are the Psychosocial Care Center II (PCC-II), the Psychosocial Care Center for Psychoactive Substance Misuse (PCC-PSM), and an Outpatient Clinic. According to data collected in a prior survey, 1,958 users were attending these services during the study period.

The selection of participants was carried out by simple random sampling. From a list of outpatient service users, the medical records of 386 users who met inclusion criteria were selected, contacted by telephone, and invited to take part in the study. Inclusion criteria were being >18 years of age and being enrolled in the service for at least one month. Individuals were excluded from the study if they reported having received a diagnosis of intellectual disability, which could compromise their ability to answer the questionnaire.
Contact with participants was initially made by telephone, at which time they were informed of their right to not participate in the research if they did not wish to do so, to cease participating in the research at any time, and to remain anonymous. Data collection was carried out in the service facilities between August and November 2019.

Data collection by questionnaire was scheduled to take place on days when patients were already attending the service for appointments or to participate in some other activity. Questionnaires were administered by six psychology undergraduate students, one physician, and one social worker. These individuals were included in the study through a selective process and received training in the application of the questionnaires.

Before applying the questionnaire, the study consent form was read aloud to the participant by the questionnaire's administrator. Participants signed the consent form after being afforded the opportunity to have any questions answered.

Measures

Timely care in Specialized Mental Health Service was defined as the user having been attended within 15 days following referral. Maintenance of a link with Primary Care after treatment at a Specialized Mental Health Service was defined as at least one contact with Primary Care services in the last 6 months, following the initial visit to the Specialized Mental Health Service.

Covariates

The independent variables included in this study were: sex (female; male); ethnicity (white; mixed race; black); age (18-30; 31-45; 46-60; 61+); schooling (0 to 4 years; 5 to 8 years; 9+ years); paid work status (unemployed; employed); per capita income (<0.5 minimum wage; 0.5 to 1 minimum wage; >1 minimum wage); diagnosis (affective and neurotic disorders; psychosis; psychoactive substance misuse; as yet undiagnosed); identification of the need for mental health care (in a crises situation; self-diagnosis followed by spontaneous demand; indicated by family and friends; in an appointment for general complaints); delay until first appointment (up to 7 days; up to 30 days; up to 90 days; up to 1 year; >1 year); first appointment service (Primary Care; emergency or hospital services; outpatient clinic; Psychosocial Care Centers; private services); referral source for current service (spontaneous demand; Primary Care; emergency or hospital services; outpatient clinic; private services); delay to access the current service (up to 7 days; up to 30 days; up to 60 days; >60 days); time attending the current service (up to 1 year; up to 3 years; up to 5 years; >5 years); previous mental health care in Primary Care (did not receive; received); Community Health Agent (CHA) visits (does not receive; does receive); and social support perception (weak; regular; strong).

Statistical analysis

Statistical analyses were conducted using Stata 15 (Stata Corporation, College Station, Texas USA). In addition to their occurrence in the overall study population, the prevalence of both outcomes was
calculated with an estimated 95% confidence interval for each of the covariates.

A weighting calibration procedure was used to reduce sample bias in relation to sex and age of the studied population. Sample weights were based on results obtained by a previous survey carried out between May and July 2019, as documented in service records.

Associations of timely care in Specialized Mental Health Services, and maintenance of a link with Primary Care with study covariates were tested using unadjusted and adjusted Poisson regression models with robust variance estimators. The adjusted analysis was carried out by the selection of confounders using forward stepwise selection among the study covariates. The selection criterion for inclusion was a p-value $\leq 0.20$ [14].

Regarding the outcome ‘timely care in Specialized Mental Health Services’ the covariates selected as potential confounders were sex, schooling, per capita income, paid work status, diagnosis, identification of the need for mental health care, delay until first appointment, and first appointment service. Covariates were adjusted among themselves, and with each of the other covariates.

Regarding the outcome ‘maintenance of a link with Primary Care’, potential confounders were sex, ethnicity, paid work status, diagnosis, source of referral to the current service, previous mental health care in Primary Care, CHA visits, and social support. Similarly, they were adjusted among themselves, and with each of the other covariates.

**Ethical procedures**

The study was approved by an accredited Ethics Committee, following the Brazilian regulatory standards and guidelines for research involving human beings (CNS Resolution 466/2012). It was similarly in accordance with the provisions of the Declaration of Helsinki.

**Results**

**Characterization of participants**

A total of 341 users of Specialized Mental Health Services were interviewed, of which 33.7% (n=115) were from PCC-II, 34.0% (n=116) were from PCC-PSM, and 32.3% were from the Outpatient Clinic. The characterization of participants according to study variables is shown in Table 1. Variables with missing data were per capita income, delay until the first appointment, and delay to access the current service. Missing observations numbered 18, 19, and 11, respectively.

**Timely care in Specialized Mental Health Services**

Information related to this outcome was obtained for 330 (96.8%) participants. The prevalence of timely care in Specialized Mental Health Services (i.e. the user having been attended within 15 days of referral)
was 60.0% (95% CI: 54-65). The prevalence of this outcome with respect to each of the variables included in the study, as well as unadjusted and adjusted relative risk values, are shown in Table 2.

There was evidence of an association of timely care in Specialized Mental Health Services and the diagnosis of psychosis (RR: 1.47; 95% CI: 1.06, 2.04) and psychoactive substance misuse (RR: 1.70; 95% CI: 1.24, 2.32).

At the same time, we identified an inverse association of timely care in Specialized Mental Health Services with the following outcomes: higher per capita income (RR: 0.74; 95% CI: 0.55, 0.99); having their need for mental health care identified in an appointment for general complaints (RR: 0.53; 95% CI: 0.32, 0.87); having been referred to the current service by Primary Care (RR: 0.61; 95% CI: 0.40, 0.93); and having attended the current service for up to 3 years.

Delay until the first appointment was also inversely associated with timely care in Specialized Mental Health Services. Except for those who took more than one year to attend their first appointment, patients who waited more than 7 days to be attended demonstrated decreased risk of the outcome in comparison to those waiting up to 30 days (RR: 0.70; 95% CI: 0.53, 0.93), up to 90 days (RR: 0.46; 95% CI: 0.31, 0.68), or up to one year (RR: 0.43; 95% CI: 0.25, 0.74).

**Maintenance of a link with Primary Care**

Information related to this outcome was obtained for all participants. The prevalence of maintaining a link with Primary Care (i.e. having attended Primary Care services at least once in the last 6 months) was 56.9% (95% CI: 51-62) for the whole sample. The prevalence of this outcome by study covariate, as well as unadjusted and adjusted relative risks, are given in Table 3.

We identified evidence of an association between the outcome ‘maintenance of a link with Primary Care’ and the referral for current service by Primary Care (RR: 1.38; 95% CI: 1.06, 1.79) and Private Services (RR: 1.66; 95% CI: 1.19, 2.32). There was also an association between the outcome and receiving visits from Community Health Agents (CHA) (RR: 1.26; 95% CI: 1.04, 1.53).

In contrast, an inverse association was found between the outcome and male sex (RR: 0.82; 95% CI: 0.67, 0.99), being employed (RR: 0.78; 95% CI: 0.60, 1.00), having a diagnosis of psychosis (RR: 0.69; 95% CI: 0.52, 0.91) or psychoactive substance misuse (RR: 0.57; 95% CI: 0.41, 0.80), and a greater perception of social support: regular (RR: 0.80; 95% CI: 0.65, 0.99), or strong (RR: 0.73; 95% CI: 0.58, 0.91).

**Discussion**

This is the first study to investigate the determinants of timely access to Specialized Mental Health Services and maintenance of a link with Primary Care. Such work augments the current evidence-base and provides further evidence for understanding the factors that affect patient’s experiences in a complex mental health network with different forms of access and the aspects that foster continuity of care.
While being referred by Primary Care to the specialized service was negatively associated with timely access, this was positively associated with maintaining the link with Primary Care. Also, in relation to the diagnosis, it can be observed that patients diagnosed with psychosis and psychoactive substance misuse were more likely to access specialized services in a timely manner, however, they were less likely to maintain the link with Primary Care. These findings contribute to the global discussion about two important challenges for better mental health care, the low integration between Primary Care services and specialized services [15] and the barriers of access that individuals with mental health and/or substance use issues face in Primary Care [16].

Previous studies have also indicated that Primary Care contact was associated with longer delays accessing specialized mental health care [1,17]. However, at the same time, this type of contact was associated with better pathways to care, fewer contacts with emergency services, and greater adherence to specialized services [17]. It appears, therefore, that the need for training Primary Care workers in the detection and management of mental health cases should be reinforced, as should be efforts to integrate the mental health care network.

Globally, several efforts have been made to establish greater integration between specialized services and Primary Care. In countries such as the United Kingdom, Spain and Canada, initiatives such as shared or collaborative care aims to link professionals and to develop strategies to collect and share information on the progress of patients [10].

It should be considered that in addition to enhancing the identification and management of mental health cases, the strengthening of this strategies could help in solving another major problem of the mental health care networks; namely, the low return of users to Primary Care levels. Previous studies have suggested that continuity of care is a critical issue when referring patients from specialized care back to Primary Care, as few people appear to reach Primary Care centers after referral [4,19].

In a study conducted in the United States with patients of a community mental health center [18], similar to our results, 41% of patients did not attend Primary Care in the six months prior to the survey. In the same study, 63% of patients were unable to identify a Primary Care provider by name and 14% reported using the emergency department for routine care.

Besides problems related to the continuity of mental health treatment, low contact with Primary Care appears to be a main contributor to the mortality gap experienced by people living with mental disorders worldwide [19]. It is estimated that this population experiences mortality rates two to three times higher than the general population, with life expectancy reduced by 10-30 years [20]. Among the factors contributing to these outcomes, there is a high prevalence in the population of hypertension, diabetes, heart disease and other conditions that could be treated by Primary Care, if identified in a timely manner [21,22].

Our results still raise an important discussion about the stigma related to psychosis and substance use. Both the greater absorption of these patients by specialized services and the lower likelihood that
they will access Primary Care after being admitted to specialized services may be related to stigma. A study conducted in the United States [23] comparing professionals at both Primary Care and secondary healthcare centres found that physicians and nurses at Primary Care had more negative attitudes toward people with psychosis than their colleagues at secondary healthcare centres.

In relation to substance use, in addition to stigma, other social issues must be observed. Studies in Latin America [24,25] have shown that although some patients occasionally access the Primary Care to obtain clinical health care, the substance use is not brought up. The professionals in turn avoid talking about the subject because they do not wish to be mistaken as informants for the police or drug dealers [24].

In relation to the action of Primary Care, our results emphasize the importance of non-medical professionals in promoting the continuity of care. Among these professionals are the CHA, whose visits to users were associated with maintaining a link with Primary Care. Through home visits, these professionals are responsible for collecting information regarding the population's health needs, identifying users with health problems, and referring them to the health unit [26]. Despite the importance of their role, however, they are often overlooked in the discussion of mental health cases management. This lack of recognition relative to other professions may stem from educational bias, as many CHA are individuals with a high school education [10].

Finally, we highlight that our results suggest that patients’ first steps in seeking help may influence other aspects of their trajectory within the health system. With the exception of those who attended their first mental health consultation after waiting more than a year, patients who waited more than 7 days to be treated were less likely to access specialized services in a timely manner (as compared to those who waited up to 7 days for treatment). These results are consistent with a review regarding the pathways to mental health care among young people [27], where the service responses to help-seeking were important determinants of patients’ pathways.

Some limitations should be considered in the interpretation of the present results. This is a cross-sectional study; therefore, reverse causality cannot be ruled out. Also, many variables were measured retrospectively, and thus are subject to recall error and bias. Additionally, it should be highlighted that this study recruited users who had access to and remained linked to specialized outpatient mental health services. Those who had previously discontinued care or did not have access to these services were therefore not included in our sample. Thus, in the city from which we drew our sample, the present results may not be representative of the full population with mental health disorders and their experiences in the mental health network.

Conclusions

Our study is an essential step towards formulating policies that ensure easier, timelier access to care and, thereby, shaping mental health patients’ outcomes. In addition to punctuating the determinants for timely access, our study also punctuates the determinants of maintaining a link with Primary Care, which is essential to bridge the mortality gap and health disparities experienced by this population worldwide.
We highlight the need to strengthen communication between Primary Care and specialized services as a measure both to qualify access in a timely manner and to promote continuity of care. In this context, the role of non-medical professionals should be highlighted, since the action of Community Health Agents has proved to be effective in fostering the link with Primary Care.

Another relevant finding is the disparity faced by patients diagnosed with psychosis and substance use issues, which may be related to the stigma attached to these diagnoses. In this sense, we reinforce the need to establish anti-stigma policies and programs, especially in Primary Care, which must be able to receive this population as a gateway to the health system.
