Thin Set Versions of Hindman’s Theorem

Denis R. Hirschfeldt and Sarah C. Reitzes

June 13, 2022

1 Introduction

This paper is part of a line of research on the computability-theoretic and
reverse-mathematical strength of versions of Hindman’s Theorem [6] that be-
gan with the work of Blass, Hirst, and Simpson [1], and has seen considerable
interest recently. We assume basic familiarity with computability theory and
reverse mathematics, at the level of the background material in [8], for in-
estance. On the reverse mathematics side, the two major systems with which
we will be concerned are RCA_0, the usual weak base system for reverse math-
ematics, which corresponds roughly to computable mathematics; and ACA_0,
which corresponds roughly to arithmetic mathematics. For principles P of
the form \((\forall X)[\Phi(X) \rightarrow (\exists Y)\Psi(X,Y)]\), we call any X such that \(\Phi(X)\)
holds an instance of P, and any Y such that \(\Psi(X,Y)\) holds a solution to X.

We begin by introducing some related combinatorial principles. For a set
S, let \([S]^n\) be the set of n-element subsets of S. Ramsey’s Theorem (RT) is
the statement that for every n and every coloring of \([N]^n\) with finitely many
colors, there is an infinite set H that is homogeneous for c, which means that
all elements of \([H]^n\) have the same color. There has been a great deal of work
on computability-theoretic and reverse-mathematical aspects of versions of
Ramsey’s Theorem, such as RT^*_k, which is RT restricted to colorings of \([N]^n\)
with k many colors. (See e.g. [8].)
The Thin Set Theorem is another variant of Ramsey’s Theorem that has been studied from this perspective. It follows easily from Ramsey’s Theorem itself.

**Definition 1.1. Thin Set Theorem (TS):** For every \( n \) and every coloring \( c : [N]^n \rightarrow \mathbb{N} \), there is an infinite set \( T \subseteq \mathbb{N} \) and an \( i \) such that \( c(s) \neq i \) for all \( s \in [T]^n \). We call such a set \( T \) a thin set for \( c \). \( TS^n \) is the restriction of \( TS \) to colorings of \( [N]^n \).

Jockusch [9] showed that there is a computable instance of \( RT_3^2 \) such that any solution computes the halting problem \( \emptyset' \). As shown by Simpson [18], Jockusch’s construction can also be used to prove that \( RT_3^2 \) (and hence \( RT \)) implies \( ACA_0 \) over \( RCA_0 \). Wang [19] showed that \( TS \), on the other hand, does not have this much power. Indeed, it has a property known as strong cone avoidance, which implies in particular that for every coloring \( c : [N]^n \rightarrow \mathbb{N} \) and every noncomputable \( X \), there is an infinite thin set for \( c \) that does not compute \( X \). It also follows from strong cone avoidance that \( TS \) does not imply \( ACA_0 \) over \( RCA_0 \).

As shown by Seetapun [17], \( RT_2^k \) also fails to imply \( ACA_0 \). Indeed, Liu [11, 12] showed that it does not imply the weaker system \( WKL_0 \), which consists of \( RCA_0 \) together with Weak König’s Lemma, or the even weaker system \( WWKL_0 \) consisting of \( RCA_0 \) together with Weak Weak König’s Lemma. Patey [14] showed that the same is true of \( TS \).

We now turn to Hindman’s Theorem. For a set \( S \subseteq \mathbb{N} \), let \( fs(S) \) be the set of sums of nonempty finite sets of distinct elements of \( S \).

**Definition 1.2. Hindman’s Theorem (HT):** For every coloring of \( \mathbb{N} \) with finitely many colors, there is an infinite set \( S \subseteq \mathbb{N} \) such that all elements of \( fs(S) \) have the same color.

Blass, Hirst, and Simpson [1] showed that such an \( S \) can always be computed in the \((\omega + 1)\)st jump of the coloring, and that there is a computable coloring such that every such \( S \) computes \( \emptyset' \). By analyzing these proofs they showed that \( HT \) is provable in \( ACA_0^+ \) (the system consisting of \( RCA_0 \) together with the statement that \( \omega \)th jumps exist) and implies \( ACA_0 \) over \( RCA_0 \). The exact computability-theoretic and reverse-mathematical strength of \( HT \) remains open.

There has recently been interest in studying restricted versions of \( HT \) such as the following. (See e.g. [2].)
Definition 1.3. \( \text{HT}^{\leq n} \) is \( \text{HT} \) restricted to sums of at most \( n \) many elements, and \( \text{HT}^{=n} \) is \( \text{HT} \) restricted to sums of exactly \( n \) many elements. \( \text{HT}^{\leq n}_{k} \) and \( \text{HT}^{=n}_{k} \) are the corresponding restrictions to colorings with \( k \) many colors.

Dzhafarov, Jockusch, Solomon, and Westrick [5] showed that \( \text{HT}^{\leq 3} \) implies ACA\(_0\) over RCA\(_0\). Carlucci, Kołodziejczyk, Lepore, and Zdanowski [3] did the same for \( \text{HT}^{\leq 2} \). These principles are also complex in a more heuristic sense: There is no known way to prove even \( \text{HT}^{\leq 2} \) other than to give a proof of the full \( \text{HT} \), which has led Hindman, Leader, and Strauss [7] to ask whether every proof of \( \text{HT}^{\leq 2} \) is also a proof of \( \text{HT} \). This question can be formalized by asking whether \( \text{HT}^{\leq 2} \) (or \( \text{HT}^{\geq 2} \)) implies \( \text{HT} \), say over RCA\(_0\). A related open question is whether \( \text{HT}^{=2} \) is provable in ACA\(_0\).

The principle \( \text{HT}^{=2} \) is quite different, as \( \text{HT}^{=2}_{k} \) follows easily from RT\(_2^{k}\). Indeed, it was not clear even whether this principle is computably true until the work of Csima, Dzhafarov, Hirschfeldt, Jockusch, Solomon, and Westrick [4], who showed that it is not, and that indeed there is a computable instance of \( \text{HT}^{\leq 2}_{2} \) with no \( \Sigma^{0}_{3} \) solutions. (The same had been shown for RT\(_2^{2}\) by Jockusch [9], who also showed that every computable instance of RT\(_2^{2}\) has a \( \Pi^{0}_{3} \) solution, which implies that the same is true of \( \text{HT}^{\geq 2}_{2} \).) They also showed that there is a computable instance of \( \text{HT}^{\geq 2}_{2} \) such that every solution has DNC degree relative to \( \emptyset' \), and adapted this proof to show that \( \text{HT}^{=2}_{2} \) implies the principle RRT\(_2^{2}\), a version of the Rainbow Ramsey Theorem, over RCA\(_0\). (See Section 3 for definitions.)

In this paper, we study further versions of Hindman’s Theorem, obtained by combining \( \text{HT} \) and its variants with the Thin Set Theorem.

Definition 1.4. thin-HT: For every coloring \( c : \mathbb{N} \to \mathbb{N} \), there is an infinite set \( S \subseteq \mathbb{N} \) such that \( f_{S}(S) \) is thin for \( c \). We define restrictions such as thin-\( \text{HT}^{\leq n} \) analogously.

In Section 2, we give similar lower bounds on the complexity of thin-HT as Blass, Hirst, and Simpson [1] gave for \( \text{HT} \), which suggests that thin-HT behaves like \( \text{HT} \) at least to some extent. Indeed, it seems possible that thin-HT is equivalent to \( \text{HT} \) over RCA\(_0\). The situation for restricted versions is different, however. Clearly, thin-\( \text{HT}^{=n} \) follows from TS\(_{n}\), but in fact so does thin-\( \text{HT}^{\leq n} \), due to the following fact.

Lemma 1.5. For each \( n \) and \( k \), the following holds in RCA\(_0\) + TS\(_{n}\): Given \( c_{i} : [\mathbb{N}]^{m_{i}} \to \mathbb{N} \) for \( i \leq k \), with \( m_{i} \leq n \) for all \( i \leq k \), there is a single infinite set \( T \) and a \( j \) such that \( c_{i}(s) \neq j \) for each \( c_{i} \) and each \( s \in [T]^{m_{i}} \) with \( i \leq k \).
Proof. We use the fact that $\text{TS}^n$ implies $\text{TS}^m$ for each $m < n$, and proceed by external induction to prove the stronger assertion that for each $j \leq k$, $\text{RCA}_0 + \text{TS}^n$ proves that there is an infinite set $T$ and an infinite set $C$ such that $c_i(s) \notin C$ for each $c_i$ and each $s \in [T]^m$ with $i \leq j$.

We do the base and inductive cases simultaneously. For $j + 1 > 0$, assume that the assertion holds for $j$ and let $T$ and $C$ be as above. For $j + 1 = 0$, let $T = C = \mathbb{N}$. Define $d : [T]^m \to \mathbb{N}$ as follows. Partition $C$ into infinitely many infinite sets $A_0, A_1, \ldots$. Let $d(s) = 0$ if either $c_{j+1}(s) \in A_0$ or $c_{j+1}(s) \notin C$, and for $i > 0$, let $d(s) = i$ if $c_{j+1}(s) \in A_i$. By $\text{TS}^{m_{j+1}}$, there is an infinite $U \subseteq T$ that is thin for $d$. Let $i \notin d([U]^m)$ and let $D = A_i$. Then $U$ and $D$ are infinite sets such that $c_i(s) \notin D$ for each $c_i$ and each $s \in [U]^m$ with $i \leq j + 1$.

This lemma allows us to get thin-$\text{HT}^{\leq n}$ from $\text{TS}^n$ by taking a coloring $c : \mathbb{N} \to \mathbb{N}$ and considering the colorings that map $\{a_0, \ldots, a_j\}$ to $c(a_0 + \cdots + a_j)$ for each $j < n$.

There are also differences that have nothing to do with computability theory and reverse mathematics between thin-$\text{HT}^{\leq n}$ on the one hand, and thin-$\text{HT}$ and $\text{HT}^{\leq n}$ on the other. The former remains true if we allow sums of non-distinct elements, but it is not difficult to show that the latter two do not. Similarly, the former remains true for colorings $S \to \mathbb{N}$, where $S \subseteq \mathbb{N}$ is any infinite set, while the latter two again do not.

Nevertheless, even thin-$\text{HT}^{=2}$ still has a significant level of complexity. In Section 2, we show that all of the lower bounds mentioned above obtained in [3] for $\text{HT}^{=2}$ still hold for thin-$\text{HT}^{=2}$.

In Section 4 we mention some open questions arising from our results, and briefly discuss version of HT obtained by combining it with thin set theorems for colorings with finitely many colors.

2 Encoding $\emptyset'$ into thin-HT

In this section, we show how to build on the proof of Theorem 2.2 of Blass, Hirst, and Simpson [1], which shows that there is a computable instance of HT such that every solution computes $\emptyset'$, to show that the same is true of thin-HT. We then derive a reverse-mathematical consequence of our proof.

**Theorem 2.1.** There is a computable instance of thin-HT such that every solution computes $\emptyset'$. 

4
Proof. As in the proof of Theorem 2.2 of [1], we write each number \( x > 0 \) as 
\[ 2^{n_0} + \ldots + 2^{n_k} \]
with \( n_0 < \ldots < n_k \), and define \( \lambda(x) = n_0 \) and \( \mu(x) = n_k \). A set \( S \) has 2-apartness if for every \( x, y \in S \) with \( x < y \), we have \( \mu(x) < \lambda(y) \).

Lemma 4.1 of [1] shows that from any infinite \( S \) we can compute an infinite set \( T \) with 2-apartness such that \( fs(T) \subseteq fs(S) \) (and hence if \( fs(S) \) is thin for any coloring, so is \( fs(T) \)).

Let \( x = 2^{n_0} + \ldots + 2^{n_k} \) with \( n_0 < \ldots < n_k \). Say that \((n_i, n_{i+1})\) is a short gap in \( x \) if there is an \( m < n_i \) such that \( m \not\in \emptyset[n_{i+1}] \) but \( m \not\in \emptyset \). Say that \((n_i, n_{i+1})\) is a very short gap in \( x \) if there is an \( m < n_i \) such that \( m \not\in \emptyset[n_{i+1}] \) but \( m \in \emptyset[n_k] \). Let \( sg(x) \) and \( vsg(x) \) be the numbers of short gaps and very short gaps in \( x \), respectively. Note that \( sg \) is not a computable function, but \( vsg \) is.

Fix a bijection between \( \mathbb{N} \) and the set of pairs \((p, i)\) where \( p \) is prime and \( 1 \leq i < p \), and identify \( \mathbb{N} \) with this set via this bijection. Define the coloring \( c \) by letting \( c(x) = (p, i) \) where \( p \) is the least prime that does not divide \( vsg(x) \) and \( vsg(x) = i \mod p \). We say that \( x \) has color \((p, i)\) if \( c(x) = (p, i) \), and we also say that \( x \) has color \((p, 0)\) or \((p, p)\) if it has color \((q, i)\) for some \( q > p \), i.e., if every prime less than or equal to \( p \) divides \( vsg(x) \).

Let \( Y \) be such that \( fs(Y) \) is an infinite thin set for \( c \). We can assume that \( Y \) has 2-apartness, by Lemma 4.1 of [1], as mentioned above. This condition ensures that if \( x, y \in fs(Y) \) and \( \mu(x) < \lambda(y) \), and we express \( x \) and \( y \) as sums of sets \( F \) and \( G \) of distinct elements of \( Y \), respectively, then \( F \) and \( G \) are disjoint, and hence \( x + y \in fs(Y) \). Say that \( S \subseteq fs(Y) \) is \( \lambda \)-bounded if there is a bound on the values of \( \lambda(x) \) for \( x \in S \) (which includes the case \( S = \emptyset \)). Note that \( fs(Y) \) itself is not \( \lambda \)-bounded. Note also that the union of finitely many \( \lambda \)-bounded sets is \( \lambda \)-bounded. Say that a color \( j \) is almost absent from \( fs(Y) \) if the set of \( x \in fs(Y) \) that have color \( j \) is \( \lambda \)-bounded. (This definition includes the case \( j = (p, 0) \), or equivalently \( j = (p, p) \).

**Lemma 2.2.** There are \( p \) and \( 0 \leq i < p \) such that \((p, i + 1)\) is almost absent from \( fs(Y) \) but \((p, i)\) is not.

*Proof.* Let \( p \) be least such that there is a \( j \) for which \((p, j)\) is almost absent from \( fs(Y) \), which exists since \( fs(Y) \) is thin. If \( p = 2 \) then \((p, j + 1)\) cannot be almost absent, since every number has color \((p, j)\) or \((p, j + 1)\). Now suppose that \( p > 2 \) and \( q \) is the preceding prime. Since \((q, 0)\) is not almost absent from \( fs(Y) \) and every number that has color \((q, 0)\) has color \((p, j)\) for some \( j \), there is some \( k \) such that \((p, k)\) is not almost absent. In either case, since having color \((p, 0)\) is the same as having color \((p, p)\), the lemma follows. \( \square \)
Fix \( p \) and \( i \) as in the above lemma.

**Lemma 2.3.** Let \( 1 \leq j < p \). Then \( S = \{ x \in fs(Y) : sg(x) = j \bmod p \} \) is \( \lambda \)-bounded.

**Proof.** Suppose \( S \) is not \( \lambda \)-bounded. Let \( q_0 < \cdots < q_{m-1} \) be the primes less than \( p \). Since there are only finitely many sequences \((k_0, \ldots, k_{m-1})\) with \( k_i < q_i \), there is such a sequence for which \( T = \{ x \in S : (\forall \ell < m) \; sg(x) = k_{\ell \bmod q_{\ell}} \} \) is not \( \lambda \)-bounded.

Since \( j \neq 0 \bmod p \), and hence \( q_0 \cdots q_{m-1} j \neq 0 \bmod p \), there is a multiple \( n \) of \( q_0 \cdots q_{m-1} \) such that \( n j = 1 \bmod p \) (where \( q_0 \cdots q_{m-1} = 1 \) if \( p = 2 \)). Since \( T \) is not \( \lambda \)-bounded, there are \( x_0 < \cdots < x_{n-1} \in T \) such that each \( \lambda(x_{k+1}) \) is sufficiently large relative to \( \mu(x_k) \) to ensure that \((\mu(x_k), \lambda(x_{k+1}))\) is not a short gap. Then the short gaps in \( x_0 + \cdots + x_{n-1} \) are exactly the short gaps in \( x_0, \ldots, x_{n-1} \), so \( sg(x_0 + \cdots + x_{n-1}) = sg(x_0) + \cdots + sg(x_{n-1}) \). The latter is equal to \( n j \bmod p = 1 \bmod p \), since each \( x_\ell \) is in \( S \), and is also equal to \( nk_\ell \bmod q_\ell \) for each \( \ell < m \), and hence equal to \( 0 \bmod q_\ell \) for each \( \ell < m \), since \( n = 0 \bmod q_\ell \).

Since \((p, i)\) is not almost absent from \( fs(Y) \), there is a \( y \in fs(Y) \) that has color \((p, i)\) such that \( \lambda(y) > \mu(x_{n-1}) \), and every number less than \( \mu(x_{n-1}) \) that is in \( \emptyset' \) is already in \( \emptyset'[\lambda(y)] \). Note that \( vsg(y) = 0 \bmod q_\ell \) for each \( \ell < m \), as otherwise \( c(y) \) would be of the form \((q_\ell, k)\) for some \( 1 \leq k < q_\ell \). Now \( vsg(x_0 + \cdots + x_{n-1} + y) = vsg(y) + sg(x_0 + \cdots + x_{n-1}) \), which is equal to \( i + 1 \bmod p \), and to \( 0 \bmod q_\ell \) for all \( \ell < m \). So \( x_0 + \cdots + x_{n-1} + y \) has color \((p, i + 1)\). As we can choose \( x_0 \) so that \( \lambda(x_0) \) is arbitrarily large, \((p, i + 1)\) is not almost absent from \( fs(Y) \), contradicting the choice of \( i \). \( \square \)

So by removing finitely many elements from \( Y \) if needed, we can assume that \( p \) divides \( sg(x) \) for all \( x \in fs(Y) \). We can now argue as in the proof of Claim 2 in the proof Theorem 2.2 of \([\Pi]\) to compute \( \emptyset' \) from \( Y \): Given \( n \), find \( x, y \in Y \) such that \( x < y \) and \( n < \mu(x) \). The short gaps in \( x + y \) are the ones in \( x \), the ones in \( y \), and possibly \((\mu(x), \lambda(y))\). But if the latter is a short gap, then \( sg(x + y) = sg(x) + sg(y) + 1 \), which is impossible since \( p \) divides all three numbers. Thus \( n \in \emptyset' \) iff \( n \in \emptyset'[\lambda(y)] \). \( \square \)

The above proof can be carried out in relativized form in \( \text{RCA}_0 \) except for two issues: One is that in \( \text{RCA}_0 \) we cannot show that the union of finitely many \( \lambda \)-bounded sets is \( \lambda \)-bounded, which in general requires the \( \Pi^0_1 \)-bounding principle. Another is that being almost absent is a \( \Sigma^0_2 \) condition, so we cannot conclude in \( \text{RCA}_0 \) that there is a least \( p \) such that there is
a \(j\) for which \((p, j)\) is almost absent from \(fs(Y)\). Since \(\Pi^0_1\)-bounding follows from \(\Sigma^0_2\)-induction over \(\text{RCA}_0\), adding the latter to \(\text{RCA}_0\) is sufficient to get around these issues, so we have the following.

**Theorem 2.4.** thin-HT implies \(\text{ACA}_0\) over \(\text{RCA}_0 + I\Sigma^0_2\).

We do not know whether the use of \(I\Sigma^0_2\) in this theorem can be removed.

### 3 Hard Instances of thin-HT\(^{=2}\)

In this section, we show that all the lower bounds on the complexity of \(\text{HT}^{=2}\) obtained by Csima, Dzhafarov, Hirschfeldt, Jockusch, Solomon, and Westrick [4] still hold for thin-HT\(^{=2}\). (Of course, all upper bounds on the complexity of \(\text{HT}^{=2}\) automatically hold for thin-HT\(^{=2}\), as the latter follows easily from the former.) As in that paper, we use the computable version of the Lovász Local Lemma due to Rumyantsev and Shen [15, 16]. In particular, we use the following consequence of Corollary 7.2 in [16] given in [4], with an addendum on uniformity as noted at the end of Section 4 of [4]. This uniformity, which in [4] is used only to obtain results on Weihrauch reducibility, will be essential in all our results, as their proofs will require applying Theorem 3.1 infinitely often.

**Theorem 3.1** (essentially Rumyantsev and Shen [16]). For each \(q \in (0, 1)\) there is an \(M\) such that the following holds. Let \(F_0, F_1, \ldots\) be a computable sequence of finite sets, each of size at least \(M\) and \(n\), there are at most \(2^m\) many \(j\) such that \(|F_j| = m\) and \(n \in F_j\), and that there is a computable procedure \(P\) for determining the set of all such \(j\) given \(m\) and \(n\). Then there is a computable \(c : \mathbb{N} \rightarrow 2\) such that for each \(j\) the set \(F_j\) is not homogeneous for \(c\). Furthermore, \(c\) can be obtained uniformly computably from \(F_0, F_1, \ldots\) and \(P\) (for a fixed \(q\)).

We will also rely in this section on arguments in [4] when they carry through in this case in an entirely analogous way.

We now introduce a notion of largeness that will be key to our iterated applications of Theorem 3.1. As in [4], we will be diagonalizing against \(\Sigma^0_2\) sets, so this notion will be defined in terms of sets that are c.e. relative to \(\emptyset'\). For a set \(A\) and a number \(s\), we write \(s + A\) for the set \(\{s + a : a \in A\}\). We write \(W_e\) for the \(e\)th enumeration operator. Given \(e\) and \(s\), for each \(x \in W_e^{\emptyset'}[s]\), let \(t_x\) be the least \(t\) such that \(x \in W_e^{\emptyset'}[u]\) for all \(u \in [t, s]\). (I.e.,
Order the elements of $W^0_e[s]$ by letting $x < y$ if either $t_x < t_y$ or both $t_x = t_y$ and $x < y$. Let $E^n_e[s]$ be the set consisting of the least $n$ many elements of $W^0_e[s]$ under this ordering, or $E^n_e[s] = [0, n]$ if $W^0_e[s]$ has fewer than $n$ many elements. If there is an $s$ such that $E^n_e[t] = E^n_e[s]$ for all $t > s$ then let $E^n_e = E^n_e[s]$.

**Definition 3.2.** For a binary function $f$, say that a set $D$ is $f$-large if for all $e$ and $k$ such that $E_f(e, k)$ is defined, we have $|D \cap (s + E_f(e, k))| \geq k$ for all sufficiently large $s$.

Note that $\mathbb{N}$ is $g$-large for the function $g(e, k) = k$, and that $f$-largeness is preserved under finite difference. The following lemma captures the key property of this notion of largeness.

**Lemma 3.3.** From a binary function $f$ and an $f$-large set $D$, we can uniformly compute a binary function $\hat{f}$ and a splitting $D = D^0 \sqcup D^1$ such that each $D^i$ is $\hat{f}$-large.

Before proving this lemma, let us derive some of its consequences, beginning with computability-theoretic lower bounds on the complexity of thin-HT=2. A function $f$ is diagonally noncomputable (DNC) relative to an oracle $X$ if $f(e) \neq \Phi^X_e(e)$ for all $e$ such that $\Phi^X_e(e)$ is defined, where $\Phi^X_e$ is the $e$th Turing functional. A degree is DNC relative to $X$ if it computes a function that is DNC relative to $X$. An infinite set $A$ is effectively immune relative to $X$ if there is an $X$-computable function $f$ such that if $W^X_e \subseteq A$ then $|W^X_e| < f(e)$.

**Theorem 3.4** (Jockusch [10]). A degree is DNC relative to $X$ if and only if it computes a set that is effectively immune relative to $X$.

The proof of the following theorem shows how to obtain a hard computable instance of thin-HT=2 from Lemma 3.3.

**Theorem 3.5.** There is a computable instance of thin-HT=2 such that any solution is effectively immune relative to $\emptyset'$, and hence has DNC degree relative to $\emptyset'$.

**Proof.** Let $D_0 = \mathbb{N}$ and $f_0(e, k) = k$. Given $D_n$ and $f_n$, let $\hat{f}_n$ and $D_n^i$ be as in Lemma 3.3, let $f_{n+1} = \hat{f}_n$, and let $D_{n+1} = D_n^1$. Note that the $D_n$ are uniformly computable. Let $c(x)$ be the largest $n \leq x$ such that $x \in D_n$. Then
$c$ is a computable coloring of $\mathbb{N}$. If $c(x) = n$ and $x > n$ then $x \in D_n$ but $x \notin D_m$ for $m > n$, so $x \in D_0$. Thus for each $n$, we have that the difference between $c^{-1}(n)$ and $D_n$ is finite, and hence $c^{-1}(n)$ is $f_n$-large.

Let $S$ be a solution to $c$ as an instance of thin-HT$^=2$, and let $n$ be such that $c(x + y) \neq n$ for all distinct $x, y \in S$. For any $e$, if $|W_e^\psi| \geq f_n(e,1)$ then $E_e^{f_n(e,1)} \subseteq W_e^\psi$ is defined, and hence $c^{-1}(n) \cap (s + E_e^{f_n(e,1)}) \neq \emptyset$ for all sufficiently large $s$. In other words, if $s$ is sufficiently large then there is an $x \in E_e^{f_n(e,1)}$ such that $c(x + s) = n$. It follows that $E_e^{f_n(e,1)} \not\subseteq S$, and hence $W_e^\psi \not\subseteq S$, since $E_e^{f_n(e,1)} \subseteq W_e^\psi$. Thus we conclude that if $W_e^\psi \subseteq S$ then $|W_e^\psi| < f_n(e,1)$. Since $f_n(e,1)$ is computable as a function of $e$, it follows that $S$ is effectively immune relative to $\emptyset'$, and hence has DNC degree relative to $\emptyset'$.

No infinite $\Sigma^0_2$ set can be effectively immune relative to $\emptyset'$, so we have the following.

**Corollary 3.6.** There is a computable instance of thin-HT$^=2$ with no $\Sigma^0_2$ solution.

It follows that thin-HT is not provable in WKL$_0$, since the latter has $\omega$-models consisting entirely of $\Delta^0_2$ sets. It was noted in [4] that HT$^{=2}$ does not imply WKL$_0$, and hence neither does thin-HT$^{=2}$. Thus thin-HT$^{=2}$ and WKL$_0$ are incomparable over RCA$_0$. In fact, as mentioned in the introduction, Patey [14] showed that TS does not imply WKL$_0$, or even WWKL$_0$, and we can easily adapt the proof of Theorem 3.5 to thin-HT$^{=n}$ for any $n > 2$, so we have the following.

**Corollary 3.7.** For each $n > 1$, both thin-HT$^{=n}$ and thin-HT$^{\leq n}$ are incomparable with (W)WKL$_0$ over RCA$_0$.

Arguing as in the proof of Corollary 3.6 of [4], we have the following.

**Corollary 3.8.** There is a computable instance of thin-HT$^{=2}$ such that all solutions are hyperimmune.

The reverse-mathematical analog of the existence of degrees that are DNC over the jump is the principle 2-DNC, defined e.g. in Section 4 of [4]. Miller [unpublished] showed that 2-DNC is equivalent, both over RCA$_0$ and in the sense of Weihrauch reducibility, to the following version of the Rainbow Ramsey Theorem, which was shown by Patey [13] to be strictly weaker than TS$^2$. 

9
Definition 3.9. RRT\textsuperscript{2} 2: Let \( c : [\mathbb{N}]^2 \rightarrow \mathbb{N} \) be such that \( |c^{-1}(i)| \leq 2 \) for all \( i \). Then there is an infinite set \( R \) such that \( c \) is injective on \([R]^2\).

As discussed in [4], the proof of Theorem 3.1 carries through in RCA\textsubscript{0}, from which it will follow that so does the proof of Lemma 3.3 that we will give below. Thus the proof of Theorem 3.5 also carries through in RCA\textsubscript{0}, except for one issue: Having \( |W_e^{\emptyset'}| \geq m \) does not necessarily imply in RCA\textsubscript{0} that \( E_m^e \) is defined. (The issue is that RCA\textsubscript{0} does not imply the \( \Pi^0_1 \)-bounding principle.) However, we can get around this problem exactly as in Section 4 of [4], by using the principle 2-EI defined there, thus obtaining the following.

Theorem 3.10. thin-HT\textsuperscript{\textsubscript{=2}} implies RRT\textsuperscript{2} 2 over RCA\textsubscript{0}.

We can also obtain a Weihrauch reduction from RRT\textsuperscript{2} 2 to a version of thin-HT\textsuperscript{\textsuperscript{=2}} as in the final paragraph of Section 4 of [4], but we have to be a bit careful because in the proof of Theorem 3.5, the function witnessing that \( S \) is effectively immune relative to \( \emptyset' \) is obtained uniformly not from \( S \), but from an \( n \) such that \( c(x + y) \neq n \) for all distinct \( x, y \in S \). Let strong thin-HT\textsuperscript{\textsuperscript{=2}} be the version of thin-HT\textsuperscript{\textsuperscript{=2}} where a solution to an instance \( c \) consists of both a solution \( S \) to \( c \) as an instance of thin-HT\textsuperscript{\textsuperscript{=2}} and an \( n \) as above. Then we have the following.

Theorem 3.11. RRT\textsuperscript{2} 2 is Weihrauch-reducible to strong thin-HT\textsuperscript{\textsuperscript{=2}}.

We do not know, however, whether this theorem remains true if we replace strong thin-HT\textsuperscript{\textsuperscript{=2}} by thin-HT\textsuperscript{\textsuperscript{=2}}.

None of the above results depend on the addition function in particular, and can be adapted as in [4] to any function \( f : [\mathbb{N}]^2 \rightarrow \mathbb{N} \) that is addition-like, which means that

1. \( f \) is computable,

2. there is a computable function \( g \) such that \( f(\{x, y\}) > n \) for all \( y > g(x, n) \), and

3. there is a \( b \) such that for all \( x \neq y \), there are at most \( b \) many \( z \)'s for which \( f(\{x, z\}) = f(\{x, y\}) \).

We finish this section by proving Lemma 3.3.
Proof of Lemma 3.3. Let \( f \) be a binary function and \( D \) an \( f \)-large set. We will apply Theorem 3.1 to obtain a computable \( c : \mathbb{N} \to 2 \). We then define \( D^i = \{ n \in D : c(n) = i \} \). The value of \( q \) will not matter here, so let us fix \( q = \frac{1}{2} \). Let \( M \) be as in Theorem 3.1.

Let \( g \) be a computable injective binary function with computable image such that \( kg(e, k) \leq 2 \frac{a(e,k)}{2} \) and \( g(e, k) \geq M \) for all \( e \) and \( k \).

Say that \( s \) is acceptable for \( e, k \) if \( |D \cap (s + E^f_e(e,kg(e,k))[s])| \geq kg(e, k) \) and for every \( t < s \) such that \( (s + E^f_e(e,kg(e,k))[s]) \cap (t + E^f_e(e,kg(e,k))[t]) \neq \emptyset \), we have \( E^f_e(e,kg(e,k))[s] = E^f_e(e,kg(e,k))[t] \). If \( s \) is acceptable for \( e, k \) then let \( F_{e, k, s, 0} \) be the first \( g(e, k) \) many elements of \( s + E^f_e(e,kg(e,k))[s] \), let \( F_{e, k, s, 1} \) be the next \( g(e, k) \) many elements of \( s + E^f_e(e,kg(e,k))[s] \), and so on, until \( F_{e, k, s, k-1} \).

Let \( \mathcal{F} \) consist of all \( F_{e, k, s, j} \) for all \( e, k \); all \( s \) acceptable for \( e, k \), and all \( j < k \). Then we can arrange the elements of \( \mathcal{F} \) into a computable sequence of finite sets, each of size at least \( M \). Fix \( x \) and \( m \). If \( m \) is not in the image of \( g \) then there are no elements of \( \mathcal{F} \) of size \( m \). Otherwise, there is a unique pair \( e, k \) such that \( m = g(e, k) \), and all elements of \( \mathcal{F} \) of size \( m \) that contain \( x \) are of the form \( F_{e, k, s, j} \) for some \( s \leq x \). We can computably determine all such sets from \( m \) and \( x \), and the definition of acceptability means that there are at most \( kg(e, k) \leq 2^m \) many such sets.

Thus the hypotheses of Theorem 3.1 hold, and hence there is a \( c \), obtained uniformly computably from \( f \) and \( D \), such that none of the sets in \( \mathcal{F} \) are homogeneous for \( c \). Let \( \hat{f}(e, k) = f(e, kg(e,k)) \) and let \( D^i = \{ n \in D : c(n) = i \} \). Fix \( e \) and \( k \) such that \( E^f_e(e,k) \) is defined. If \( s \) is sufficiently large then \( s \) is acceptable for \( e, k \), and \( F_{e, k, s, j} \subseteq s + E^f_e(e,k) \) for all \( j < k \). For each \( j < k \) and \( i < 2 \), there is at least one \( x \in F_{e, k, s, j} \) such that \( c(x) = i \). Since the \( F_{e, k, s, j} \) are disjoint, \( |D^i \cap (s + E^f_e(e,k))| \geq k \). Thus \( D^i \) is \( \hat{f} \)-large. \( \square \)

4 Open Questions

In this section, we collect a few open questions and possible directions for further work arising from the above results.

**Question 4.1.** Does thin-HT imply ACA\(_0\) over RCA\(_0\) (i.e., without assuming IΣ\(_2^0\))?

Of course, one way to give a positive answer to this question would be to show that thin-HT implies IΣ\(_2^0\) over RCA\(_0\). If that is not the case, then it
could be interesting to try to determine the first-order part of thin-HT.

**Question 4.2.** Is thin-HT provable in ACA₀?

**Question 4.3.** Does thin-HT imply HT, say over RCA₀?

In the spirit of Hindman, Leader, and Strauss [7], we can also ask the less formal question of whether there is a proof of thin-HT that is not already a proof of HT.

**Question 4.4.** Is RRT SEXPREDUCIBLE to thin-HT=² (as opposed to strong thin-HT=²)?

**Question 4.5.** What is the exact relationship between thin-HT=² and each of TS², RRT², and HT=²?

There are also versions of the Thin Set Theorem for colorings with finitely many colors. For example, an instance of TSⁿₖ is a coloring c of [N]ⁿ with k many colors, and a solution to this instance is an infinite set T such that |c([T]ⁿ)| < k. This principle and RTⁿₖ form the two ends of a spectrum of principles RTⁿₖ,j for 1 ≤ j < k, where an instance is a coloring c of [N]ⁿ with k many colors, and a solution to this instance is an infinite set T such that |c([T]ⁿ)| ≤ j. It would be interesting to pursue versions of HT based on these principles. One might hope to show, for instance, that there is a boundary between principles that “behave like HT”, e.g. HT=²², which as mentioned in the introduction was shown to imply ACA₀ in [3]; and those that “behave like versions of TS / RT”, e.g. the thin version of HT=²₂, which can easily be shown to follow from RT²_{4,2}.
