Abstract. We study homological properties of a locally complete intersection ring by importing facts from homological algebra over exterior algebras. One application is showing that the thick subcategories of the bounded derived category of a locally complete intersection ring are self-dual under Grothendieck duality. This was proved by Stevenson when the ring is a quotient of a regular ring modulo a regular sequence; we offer two independent proofs in the more general setting. Second, we use these techniques to supply new proofs that complete intersections possess symmetry of complexity.

Introduction

Homological algebra over complete intersections is profoundly linked to the homological algebra over exterior algebras. This was clarified in [4] where Avramov and Iyengar established a process to obtain homological information over complete intersections from the corresponding results over graded Hopf algebras. Their techniques provided new, easier proofs of many known results over complete intersections.

For example, the complexity of a module measures the polynomial rate of growth of its Betti numbers while the injective complexity measures the polynomial rate of growth of the module’s Bass numbers. Using the process described above, Avramov and Iyengar easily deduced that over complete intersections the complexity of a module agrees with its injective complexity, and both of these values are bounded above by the complexity of the residue field; they also employ their methods to show the latter is exactly the codimension of the complete intersection.

In this article, we adopt techniques from [4] to acquire further information about complete intersections. For the rest of the introduction $R$ is a commutative noetherian ring. The first main result is framed in terms of the derived category of $R$, denoted $\mathcal{D}(R)$.

We let $\mathcal{D}^f(R)$ denote the full subcategory of $\mathcal{D}(R)$ consisting of those complexes of $R$-modules whose total homology is finitely generated. It inherits the structure of a triangulated category from $\mathcal{D}(R)$. Recently, there has been much interest in understanding the structure of thick subcategories of $\mathcal{D}^f(R)$, see for example [3, 8, 9, 12, 15, 17, 19]. Our first main result is the following:

2010 Mathematics Subject Classification. 13D09 (primary); 13D07, 13H10, 16E45 (secondary).

Key words and phrases. complete intersections, thick subcategories, exterior algebra, Koszul complex, DG algebra, DG module, support variety, duality, complexity.

The first author thanks the China Scholarship Council for financial support to visit Srikanth Iyengar at the University of Utah.

The second author was supported by the National Science Foundation under Grant No. 1840190.
Theorem 1. If $R$ is locally complete intersection, then each thick subcategory of $\mathcal{D}^f(R)$ is self-dual under Grothendieck duality. That is, for any thick subcategory $T$ of $\mathcal{D}^f(R)$ and object $M$ in $T$, $\mathbb{R}Hom_R(M, R)$ is in $T$, as well.

Stevenson in [17, 4.11] proved the result under the additional assumption that $R$ is a quotient of a regular ring modulo a regular sequence. One can also deduce Theorem 1 from [17, 4.11] in conjunction with recent results of Letz [12, 3.12 & 4.5]; details are provided in Remark 3.4.

In this article, we present two proofs of Theorem 1 both of which rely on a local-to-global principle of Benson, Iyengar and Krause (see 1.6) and the structure of thick subcategories in the derived category of an exterior algebra over a field (cf. [8]). The first proof uses the theory of cohomological support discussed in Section 2. Namely, we show that the containment of thick subcategories is encoded in the support varieties of Avramov and Buchweitz defined in [2] (see Theorem 3.1 for a precise statement).

The second proof makes direct use of the graded Hopf algebra structure of the exterior algebra to show that thick subcategories over an exterior algebra on generators of homological degree one are fixed by Grothendieck duality (see Theorem 4.1). Furthermore, it is worth noting that the both of the proofs of Theorem 3.3 do not rely on the full classification of thick subcategories in [18, 8.8]; making the proofs here simpler even in the case that $R$ is a quotient of a regular ring modulo a regular sequence.

As a consequence of Theorem 1 we obtain asymptotic information over complete intersections. For example, we recover a result of Avramov and Buchweitz [2, 6.3] that says the eventual vanishing of Ext is equivalent to the eventual vanishing of Tor over locally complete intersections (cf. Corollary 3.5). Furthermore, in the local case we can use Theorem 1 to show complexity is symmetric in $M$ and $N$; recall the complexity of a pair of objects $M$ and $N$ of $\mathcal{D}^f(R)$ is the polynomial rate of growth of the minimal number of generators of $\text{Ext}^n_R(M, N)$ (see 5.1 for a precise definition).

Theorem 2. If $R$ is complete intersection, then $\text{cx}_R(M, N) = \text{cx}_R(N, M)$ for each pair of objects $M$ and $N$ in $\mathcal{D}^f(R)$.

This was first proven by Avramov and Buchweitz [2]; an alternative proof was provided by the second author in [14]. In contrast, we give two new proofs of this result in this paper; both of which use the homological properties over exterior algebras. The first proof deduces Theorem 2 from Theorem 1, illustrating how the containment of thick subcategories and duality can provide asymptotic information. The second proof directly links the complexity of a pair of objects $M$ and $N$ in $\mathcal{D}^f(R)$ with the complexity of a pair of objects in the derived category of an exterior algebra over a field. This proof fills in a missing piece of the work in [4]; cf. [4, 6.9] and the discussion in Remark 5.4.

Acknowledgements. Both authors are indebted to Srikanth Iyengar for many helpful discussions, as well as suggesting the two authors collaborate because of their many common interests. We are also very happy to thank Benjamin Briggs for several useful comments on an earlier draft of this paper as well as numerous conversations that helped clarify some ideas in Section 4. We also thank Janina Letz and Greg Stevenson for their comments on a preliminary draft of this work.
1. Background, Notation, and Terminology

Throughout this article $R$ will be a commutative noetherian ring.

1.1. (Locally) Complete Intersections. Suppose $(R, m, k)$ is local. Recall the embedding dimension of $R$ is $\dim_k m/m^2$, the minimal number of generators for $m$, and the codimension of $R$ is

$$\dim_k m/m^2 - \dim R.$$

A local ring $(R, m, k)$ is complete intersection if its $m$-adic completion $\widehat{R}$ is isomorphic to $Q/I$ where $Q$ is a regular local ring and $I$ is generated by a $Q$-regular sequence. In fact, the presentation can be chosen so that $Q$ and $R$ have the same embedding dimension and $I$ is generated by $c$ elements where $c$ is the codimension of $R$.

More generally, $R$ is locally complete intersection provided that the local ring $R_p$ is complete intersection for each prime ideal $p$ of $R$.

1.2. Derived Category of a DG Algebra. Let $A$ be a DG $R$-algebra. We briefly discuss the derived category of DG $A$-modules and set notation used throughout the rest of the article. See [3, Section 3] or [10, Chapter 6] for more details.

Let $D(A)$ denote the derived category of (left) DG $A$-modules. Recall that $D(A)$ is a triangulated category with $\Sigma$ being the suspension functor; for each $X$ in $D(A)$, $\Sigma X$ is the DG $A$-module given by $\Sigma X_\ell = X_{\ell-1}$, $a \cdot (\Sigma x) = (-1)^{|a|} ax$ and $\partial \Sigma X = -\partial X$. We let $D_f(A)$ denote the full subcategory of $D(A)$ consisting of those objects $X$ of $D(A)$ such that $H(X)$ is a finitely generated graded $H(A)$-module.

Each DG $A$-module $X$ admits a semiprojective resolution. That is, there exists a surjective quasi-isomorphism $P \to M$ such that $\text{Hom}_A(P, -)$ preserves surjective quasi-isomorphisms. For any $Y$ in $D(A)$, we set

$$\text{RHom}_A(X, Y) := \text{Hom}_A(P, Y)$$

where $P \to X$ is a semiprojective resolution and

$$\text{Ext}_A(X, Y) := H(\text{RHom}_A(X, Y)),$$

which naturally inherits a graded $\text{Ext}_A(Y, Y)$-$\text{Ext}_A(X, X)$-bimodule structure.

1.3. Koszul Complexes. Background on Koszul complexes can be found in [7, Section 1.6]. We recall the necessary facts here.

For a list of elements $x = x_1, \ldots, x_n$ in $R$, we set $\text{Kos}^R(x)$ to be the Koszul complex of $x$ on $R$, which is regarded as a DG $R$-algebra in the usual way.

When $R$ is local with maximal ideal $m$, set $K^R$ to be the Koszul complex on a minimal generating set for $m$. It is well-defined up to an isomorphism of DG $R$-algebras.

Fix a prime ideal $p$ of $R$ and let $M$ be an object of $D(R)$. We set

$$M(p) := M_p \otimes_{R_p} K^R_p$$

which is a DG $K^R_p$-module. Restricting scalars along the morphism of DG algebras $R_p \to K^R_p$ we may regard $M(p)$ as an object of $D(R_p)$. 
1.4. Koszul Complexes over Complete Intersections. Let \((R, m, k)\) be complete intersection of codimension \(c\) and \(Λ\) be the exterior algebra over \(k\) on generators \(e_1, \ldots, e_c\) of homological degree 1. Let \(t : D(R) \to D(KR)\) be the functor 

\[ t \colon D(R) \to D(KR) \]

By [4, 6.4] there is a quasi-isomorphism of DG algebras \(KR \simeq Λ\) that induces an equivalence of triangulated categories \(j; D(KR) \to D(Λ)\); this restricts to an equivalence \(D^f(KR) \cong D^f(Λ)\) that is compatible with Grothendieck duality (see [3, 3.6] or [4, 2.5]). Hence, when \(R\) is complete intersection we have the following composition

\[ jt : D^f(R) \to D^f(KR) \cong D^f(Λ) ; \]

this is the main bridge for importing results over graded exterior algebras to complete intersections. Throughout the rest of the paper, \(j\) and \(t\) will always denote the functors introduced here.

1.5. Thick Subcategories. Let \(A\) be a DG algebra and \(T\) be a full subcategory of \(D(A)\). We say \(T\) is thick if it is a triangulated subcategory that is closed under taking direct summands. For an object \(M\) of \(D(A)\), we let \(\text{thick}_{D(A)}(M)\) denote the smallest thick subcategory of \(D(A)\) containing \(M\). This can be realized as the intersection of all thick subcategories of \(D(A)\) containing \(M\); alternatively, this has an inductive construction discussed in [3, 2.24].

1.6. Local-to-Global Principle. The main results in the present paper rely on the following local-to-global principle of Benson, Iyengar and Krause (see by [6, 5.10]). Namely, for objects \(M\) and \(N\) of \(D^f(R)\), \(M\) is in \(\text{thick}_{D(R)}(N)\) if and only if \(M(p)\) is in \(\text{thick}_{D(R_p)}(N_p)\) for each prime ideal \(p\) of \(R\). As \(N(p)\) is an object of \(\text{thick}_{D(R_p)}(N_p)\), we restate the local-to-global principle as:

\[ M \text{ is in } \text{thick}_{D(R)}(N) \iff M(p) \text{ is in } \text{thick}_{D(R_p)}(N(p)) \]

for each prime ideal \(p\) of \(R\).

1.7. Homogeneous Support. Let \(S\) be a commutative noetherian graded ring. We let \(\text{Spec}^* S\) denote the homogeneous spectrum of \(S\). That is, \(\text{Spec}^* S\) consists of the homogeneous prime ideals of \(S\). For a graded \(S\)-module \(X\) and \(p \in \text{Spec}^* S\), \(X_p\) denotes the homogeneous localization of \(X\) at \(p\). The homogeneous support of \(X\) is

\[ \text{supp}_{\nu} X = \{ p \in \text{Spec}^* S : X_p \neq 0 \}. \]

2. Cohomological Support Varieties

Throughout this section we fix the following notation. Let \((R, m, k)\) be complete intersection with codimension \(c\) and embedding dimension \(ν\). Let \(S\) denote the graded \(k\)-algebra \(k[\chi_1, \ldots, \chi_c]\) where each \(\chi_i\) has homological degree \(-2\). We set \(Λ\) to be the exterior algebra over \(k\) on generators \(e_1, \ldots, e_c\) of homological degree 1. Finally, let \(j\) and \(t\) be the functors from 1.4.

2.1. In [16, Theorem 5], Sjödin described the graded \(k\)-algebra structure of \(\text{Ext}_R(k, k)\). It contains \(S\) as a polynomial subalgebra in such a way that

\[ \text{Ext}_R(k, k) \cong S \otimes_k \bigwedge \Sigma^{-1} k^ν \]
as graded $S$-modules; see also [1, 10.2.3] for more details. Thus, $S$ acts on $\text{Ext}_R(k, M)$ through the $\text{Ext}_R(k, k)$-action for each $M$ in $D(R)$. We define the cohomological support of $M$ over $R$ to be

$$V_R(M) := \text{supp}_S \text{Ext}_R(k, M).$$

2.2. By [4, 5.1] (see also [3, 7.4]), there is an isomorphism of graded $k$-algebras

$$\text{Ext}_\Lambda(k, k) \cong S.$$ 

For any $X$ in $D(\Lambda)$, we define the cohomological support of $X$ over $\Lambda$ to be

$$V_\Lambda(X) := \text{supp}_S \text{Ext}_\Lambda(k, X).$$

These varieties can detect the containment of thick subcategories in $D(\Lambda)$. Namely, in [8, 4.4], Carlson and Iyengar showed $X$ is in thick $D(\Lambda) \iff V_\Lambda(X) \subseteq V_\Lambda(Y)$ for any pair of objects $X$ and $Y$ in $D(\Lambda)$. This essentially follows from the celebrated theorem of Hopkins [11, 11] and Neeman [13, 1.2] (see also [8, 3.2] for the version needed) and a BGG correspondence (cf. [3, 7.4]).

There is a way to relate the supports defined over $R$ and $\Lambda$. This was first noticed in the case that $R$ is artinain [8, 5.11]; however, the same proof works without any restriction on the Krull-dimension of $R$ and so we sketch it for the convenience of the reader in the following remark and lemma.

2.3. First, there is a canonical injective map $\eta: \text{Ext}_\Lambda(k, k) \rightarrow \text{Ext}_R(k, k)$ of graded $k$-algebras that can be factored as

$$_{\text{ext}} \text{Ext}_\Lambda(k, k) \rightarrow \text{Ext}_K R(k, k) \rightarrow \text{Ext}_R(k, k)$$

where the isomorphism is induced by the inverse of the equivalence $j$ from 1.4. Moreover, the image of $\eta$ is exactly the polynomial subalgebra $S$ of $\text{Ext}_R(k, k)$ mentioned in 2.1. Therefore, the cohomological supports over $R$ and those over $\Lambda$ can naturally be thought of as subsets of the same $\text{Spec}^* S$. Moreover, we have the following connection.

Lemma 2.4. For each $M$ in $D(R)$, $V_R(M) = V_R(tM) = V_\Lambda(jtM)$.

Proof. First, consider the isomorphisms of graded $S$-modules

$$\text{Ext}_R(k, tM) \cong \text{Ext}_K R(tk, tM) \cong \text{Ext}_\Lambda(jtk, jtM) \cong \bigoplus_{i=0}^\nu \Sigma^{-i} \text{Ext}_\Lambda(k, jtM)({}^i\!).$$

where the third isomorphism holds because $tk \cong \bigoplus_{i=0}^\nu \Sigma^{-i}k({}^i\!)$ and $j(k) \simeq k$, see [3, 3.9] for the latter. Also, we have the isomorphism of graded $S$-modules

$$\text{Ext}_R(k, tM) \cong \bigoplus_{i=0}^\nu \Sigma^i \text{Ext}_R(k, M)({}^i\!).$$

Therefore, the isomorphisms of $S$-modules show

$$V_R(M) = V_R(tM) = V_\Lambda(jtM).$$
Proposition 2.5. For \( M \) and \( N \) in \( D^I(R) \),
\[
\text{t}M \text{ is in } \text{thick}_{D(R)}(\text{t}N) \iff V_R(M) \subseteq V_R(N).
\]

Proof. The forward direction is trivial from the first equality in Lemma 2.4. Conversely, assume \( V_R(M) \subseteq V_R(N) \). Using Lemma 2.4, this reads as \( V_A(\text{jt}M) \subseteq V_A(\text{jt}N) \).

Thus, 2.2 implies that \( \text{jt}M \) is an object of \( \text{thick}_{D(\Lambda)}(\text{jt}N) \). As \( j \) is an equivalence we conclude that \( \text{t}M \) is an object of \( \text{thick}_{D(K^R)}(\text{t}N) \). The result follows by restricting scalars along the morphism of DG \( R \)-algebras \( R \to K^R \). □

We end this section with the following technical lemma which will be put to use in Section 4. Note that since \( \Lambda \) has trivial differential, for each DG \( \Lambda \)-module \( X \) we can negate differential of \( X \) to obtain a DG \( \Lambda \)-module. Namely, let \( X' \) denote the DG \( \Lambda \)-module whose underlying graded \( \Lambda \)-module is \( X \) and its differential is \( \partial X' := -\partial X \). When \( \Lambda \) is concentrated in even degrees, \( X \cong X' \) as DG \( \Lambda \)-modules (cf. 4.3). However, as the generators of \( \Lambda \) have degree 1 we do not know whether these are isomorphic. Instead, we show they have the same cohomological support, and hence, generate the same thick subcategory.

Lemma 2.6. If \( X \) is in \( D^I(\Lambda) \), then \( V_\Lambda(X) = V_\Lambda(X') \). Moreover, we have the following equality of thick subcategories:
\[
\text{thick}_{D(\Lambda)}(X) = \text{thick}_{D(\Lambda)}(X').
\]

Proof. By [8, 4.2], there exists a semiprojective resolution \( F \xrightarrow{\sim} k \) over \( \Lambda \) such that \( F \) admits a DG \( S \)-module structure compatible with the \( S \)-action on \( \text{Ext}_R(k, Y) \) for any \( Y \) in \( D(\Lambda) \). As \( k \) has trivial differential, the same is true of the semiprojective DG \( \Lambda \)-resolution equipped with a DG \( S \)-module structure \( F' \xrightarrow{\sim} k \).

Define \( \Phi : \text{Hom}_\Lambda(F, X) \to \text{Hom}_\Lambda(F', X') \) given by
\[
\alpha \mapsto (-1)^{|\alpha|} \alpha.
\]
As \( S \) is concentrated in even degrees this is an isomorphism of DG \( S \)-modules. Therefore, \( H(\Phi) \) establishes the following isomorphism of graded \( S \)-modules
\[
\text{Ext}_\Lambda(k, X) \cong \text{Ext}_\Lambda(k, X');
\]
so \( X \) and \( X' \) have the same cohomological support. The equality of thick subcategories now follows from 2.2. □

3. Duality of Thick Subcategories via Support

In this section we give the first proof of our result on the duality of thick subcategories over locally complete intersections (see Theorem 3.3). The main idea behind it is that the theory of cohomological supports, discussed in Section 2, both detects containment of thick subcategories and is unaffected by duality. The first theorem addresses the former point while 3.2 the latter.

Theorem 3.1. Let \( R \) be locally complete intersection. For \( M, N \) in \( D^I(R) \),
\[
M \text{ is in } \text{thick}_{D(R)}(N) \iff V_{R_p}(M_p) \subseteq V_{R_p}(N_p)
\]
for each prime ideal \( p \) of \( R \).
Proof. First, assume \( M \) is an object of \( \text{thick}_{D(R)} N \). Hence, \( M_p \) is an object of \( \text{thick}_{D(R_p)} N_p \) and so it follows easily that \( V_{R_p}(M_p) \subseteq V_{R_p}(N_p) \) for each \( p \in \text{Spec} \, R \).

Conversely, suppose \( V_{R_p}(M_p) \subseteq V_{R_p}(N_p) \) for each \( p \in \text{Spec} \, R \). By Proposition 2.5, \( M(p) \) is in \( \text{thick}_{D(R_p)}(N(p)) \) for each prime ideal \( p \) of \( R \). Finally, we apply 1.6 to conclude that \( M \) is in \( \text{thick}_{D(R)}(N) \). \( \square \)

3.2. It is well-known that cohomological support over complete intersections is closed under duality. That is,

\[
V_R(M) = V_R(\text{RHom}_R(M, R))
\]

for each \( M \) in \( D^f(R) \). This was shown for closed points of \( \text{Spec}^* \, S \) in [2, 3.3], and the general setting was shown in [14, 4.1.5]. Alternatively, a new proof is obtained in the present work by combining Lemma 2.4 and Theorem 4.1; this proof sticks with the theme of establishing results for complete intersections by passing to an exterior algebra.

**Theorem 3.3.** If \( R \) is locally complete intersection, then every thick subcategory of \( D^f(R) \) is closed under \( \text{RHom}_R(\cdot, R) \). In particular, for each \( M \) in \( D^f(R) \)

\[
\text{thick}_{D(R)}(M) = \text{thick}_{D(R)}(\text{RHom}_R(M, R)).
\]

*First proof of Theorem 3.3.* As \( M \) is an object of \( D^f(R) \), there is a natural isomorphism

\[
\text{RHom}_R(M, R)_p \cong \text{RHom}_{R_p}(M_p, R_p)
\]

for each prime ideal \( p \) of \( R \). So 3.2 shows

\[
V_{R_p}(M_p) = V_{R_p}(\text{RHom}_{R_p}(M_p, R_p)) = V_{R_p}(\text{RHom}_R(M, R)_p)
\]

for each prime ideal \( p \) of \( R \). Now we obtain

\[
\text{thick}_{D(R)}(M) = \text{thick}_{D(R)}(\text{RHom}_R(M, R))
\]

as an immediate consequence of Theorem 3.1. \( \square \)

**Remark 3.4.** Theorem 3.3 can also be proved by combining results of Stevenson and Letz (see [17, 4.11] and [12, 3.12 & 4.5], respectively). Stevenson used his classification of thick subcategories of the singularity category of a regular ring modulo a regular sequence in [18, 8.8] to show Theorem 3.3 holds for such rings. Letz showed for \( M \) and \( N \) in \( D^f(R) \),

\[
M \text{ is in } \text{thick}_{D(R)}(N) \iff M \otimes \widehat{R_p} \text{ is in } \text{thick}_{D(\widehat{R_p})}(N \otimes_R \widehat{R_p})
\]

for each prime ideal \( p \) of \( R \) where \( \widehat{R_p} \) is the \( pR_p \)-adic completion of \( R_p \). So their work, indeed, offers a different argument for Theorem 3.3.

In Section 4, we give our second proof of Theorem 3.3. This requires an analysis of duality over a graded exterior algebra which is discussed there. We end this section with the following application that recovers a theorem of Avramov and Buchweitz [2, 6.3]. In Section 5, we strengthen the equivalence of (1) and (2) in Corollary 3.5 when \( R \) is further assumed to be local.

**Corollary 3.5.** Let \( R \) be locally complete intersection. For \( M \) and \( N \) in \( D^f(R) \), the following are equivalent:

1. \( \text{Ext}^i_R(M, N) = 0 \) for all \( i \gg 0 \);
2. \( \text{Ext}^i_R(N, M) = 0 \) for all \( i \gg 0 \);
Theorem 4.1. For an object $M$ of $D^f(\Lambda)$,

$$\text{thick}_{D(\Lambda)}(M) = \text{thick}_{D(\Lambda)}(R\text{Hom}_\Lambda(M, \Lambda)).$$

4.2. Let $\rho \colon \Lambda \to \Lambda$ be an anti-endomorphism of graded $k$-algebras, which is nothing more than an endomorphism since $\Lambda$ is graded-commutative. The map $\rho$ prescribes a natural left DG $\Lambda$-module structure on the graded $k$-space $M^* = \text{Hom}_k(M, k)$; define $M^*(\rho)$ to be the left DG $\Lambda$-module whose underlying graded $k$-space is $M^*$ and its differential and $\Lambda$-action are given by

$$\partial^{M^*}(\rho)(f) := -(\partial f) \cdot f = (-1)^{|f|} f \partial M = (-1)^{|f|+1} f \partial M$$

$$a \cdot f := (-1)^{|a||f|} f(\rho(a)) -.$$
We are particularly interested in the relationship between $M^*(\text{id})$ and $M^*(\sigma)$. Furthermore, as $\text{Hom}_k(\Lambda, k) \cong \Sigma^{-c} \Lambda$ as DG $\Lambda$-modules a direct calculation yields

\[(1) \quad R\text{Hom}_\Lambda(M, \Lambda) \cong \Sigma^c \text{Hom}_k(M, k) = \Sigma^c M^*(\text{id}).\]

4.3. Let $M$ be a DG $\Lambda$-module. Since $\Lambda$ has trivial differential we can twist the differential and $\Lambda$-action of $M$ to obtain an isomorphic DG $\Lambda$-module. We define $M_\tau$ to be the DG $\Lambda$-module whose underlying graded $k$-space is $M$ equipped with $\partial M_\tau := (-1)^{|a|} am$.

The map $M \rightarrow M_\tau$ given by $m \mapsto (-1)^{|m|} m$ is easily checked to be an isomorphism of DG $\Lambda$-modules.

**Proposition 4.4.** For any $M$ in $\text{D}(\Lambda)$, $M^*(\sigma)$ and $M^*(\text{id})_\tau$ have the same underlying graded $\Lambda$-module while their differentials are negatives of one another.

**Proof.** This follows directly from the definitions in 4.2 and 4.3. \[\Box\]

4.5. Let $M$ and $N$ be left DG $\Lambda$-modules, then $M \otimes_k N$ is a left DG $\Lambda \otimes_k \Lambda$-module. We define $\text{Hom}_k(M, N)$ to be a left DG $\Lambda \otimes_k \Lambda$-module

\[\partial \text{Hom}_k(M, N)(f) := \partial^N f - (-1)^{|f|} f \partial^M\]

\[(a_1 \otimes a_2) \cdot f := (-1)^{|a_2||f|} a_1 f(\sigma(a_2)-).\]

Hence, both $M \otimes_k N$ and $\text{Hom}_k(M, N)$ inherit a DG $\Lambda$-module structure via $\Delta$.

There is a natural morphism of DG $\Lambda$-modules

\[\varphi_{M,N} : N \otimes_k M^*(\sigma) \rightarrow \text{Hom}_k(M, N)\]

which is an isomorphism in $\text{D}(\Lambda)$ when $H(M)$ is a finite rank $k$-space (see [4, 4.8]).

4.6. Let $M$ be a DG $\Lambda$-module. Consider the morphism of DG $\Lambda$-modules

\[\pi_M : k \rightarrow \text{Hom}_k(M, M)\]

mapping 1 to $\text{id}_M$.

\[M \cong k \otimes_k M \xrightarrow{\pi_M \otimes M} \text{Hom}_k(M, M) \otimes_k M.\]

For an object $M$ in $\text{D}^f(\Lambda)$ the composition

\[M \cong k \otimes_k M \xrightarrow{\pi_M \otimes M} \text{Hom}_k(M, M) \otimes_k M \xrightarrow{\varphi_{M,M,M}^{-1} \otimes M} M \otimes_k M^*(\sigma) \otimes_k M\]

splits in $\text{D}^f(\Lambda)$; this is essentially the same argument from the classical case (cf. [5, 3.1.10]).

**Proof of Theorem 4.1.** As $\text{thick}_{\text{D}(\Lambda)}(k) = \text{D}^f(\Lambda)$, it follows that

\[M \otimes_k M^*(\sigma) \otimes_k M \text{ is an object of } \text{thick}_{\text{D}(\Lambda)}(M^*(\sigma)).\]

Hence, 4.6 implies that $M$ is in $\text{thick}_{\text{D}(\Lambda)}(M^*(\sigma))$, as well. Since $(M^*(\sigma))^*(\sigma) \cong M$, then by symmetry we have shown

\[(2) \quad \text{thick}_{\text{D}(\Lambda)}(M) = \text{thick}_{\text{D}(\Lambda)}(M^*(\sigma)).\]
Now we only need to observe that
\[
\text{thick}_{D(\Lambda)}(M) = \text{thick}_{D(\Lambda)}(M^*(\sigma))
\]
\[
= \text{thick}_{D(\Lambda)}(M^*(\sigma), -\partial^{M^*(\sigma)})
\]
\[
= \text{thick}_{D(\Lambda)}(M^*(\text{id}))
\]
\[
= \text{thick}_{D(\Lambda)}(\text{RHom}_{\Lambda}(M, \Lambda))
\]
where the first equality holds by (2), the second equality is Lemma 2.6, the third equality is from 4.3 and Proposition 4.4, and the last equality holds by 4.2(1). Therefore, we have justified the theorem. □

As an application of the theory above (in particular, Theorem 4.1) we now present a second proof of Theorem 3.3.

Second proof of Theorem 3.3. First, if \( R \) is complete intersection we show that for any \( M \) in \( D^f(R) \),
\[
(3) \quad \text{thick}_{D(R)}(M \otimes_R K^R) = \text{thick}_{D(R)}(\text{RHom}_R(M, R) \otimes_R K^R).
\]

Now observe that Theorem 4.1 shows
\[
\text{thick}_{D(\Lambda)}(j t M) = \text{thick}_{D(\Lambda)}(\text{RHom}_{\Lambda}(j t M, \Lambda))
\]
where \( j \) and \( t \) are the functors introduced in 1.4. Therefore,
\[
\text{thick}_{D(K^R)}(t M) = \text{thick}_{D(K^R)}(\text{RHom}_{K^R}(t M, K^R))
\]
and since
\[
\text{RHom}_{K^R}(t M, K^R) \cong t \text{RHom}_R(M, R)
\]
it follows that
\[
\text{thick}_{D(K^R)}(t M) = \text{thick}_{D(K^R)}(t \text{RHom}_R(M, R)).
\]
So restricting scalars along \( R \rightarrow K^R \) finishes the proof of (3) in the case that \( R \) is complete intersection.

Now we return to the general setting; namely, assume that \( R \) is locally complete intersection. Let \( p \) be a prime ideal of \( R \), then by assumption \( R_p \) is complete intersection and
\[
\text{thick}_{D(R_p)}(M(p)) = \text{thick}_{D(R_p)}(\text{RHom}_{R_p}(M_p, R_p) \otimes_{R_p} K^{R_p})
\]
\[
= \text{thick}_{D(R_p)}(\text{RHom}_R(M, R)(p));
\]
the first equality is from the already established equality (3) and the second equality is immediate from the isomorphism
\[
\text{RHom}_{R_p}(M_p, R_p) \otimes_{R_p} K^{R_p} \cong \text{RHom}_R(M, R) \otimes_R K^{R_p}.
\]
Since these equalities of thick subcategories hold for each prime ideal \( p \) of \( R \), an application of the local-to-global principle in 1.6 establishes the desired result. □
5. Symmetry of Complexity

In this section, we offer two proofs of Theorem 5.2; both methods indicate how the symmetry of complexity over complete intersections follow from studying properties of exterior algebras. Theorem 5.2 was originally shown in [2, 5.7] using support varieties and the use of intermediate hypersurfaces. A second proof was given by the second author in [14, 4.3.1] by studying the cohomological support of certain DG modules over a graded commutative ring of finite global dimension.

Throughout this section \((R, m, k)\) is a commutative noetherian local ring. Also, we let \((-)^\vee\) denote the functor \(R\text{Hom}_R(-, R)\).

5.1. Let \(M\) and \(N\) be in \(D^f(R)\). The complexity of the pair \((M, N)\), denoted \(\text{cx}_R(M, N)\), is the least non-negative integer \(d \in \mathbb{N}\) such that

\[
\dim_k(\text{Ext}^n_R(M, N) \otimes_R k) \leq an^{d-1}
\]

for all \(n \gg 0\) and some \(a \in \mathbb{R}\). That is, \(\text{cx}_R(M, N)\) measures the polynomial rate of growth of the minimal number of generators of \(\text{Ext}^n_R(M, N)\).

Theorem 5.2. Let \(R\) be complete intersection. For each pair of objects \(M\) and \(N\) in \(D^f(R)\),

\[
\text{cx}_R(M, N) = \text{cx}_R(N, M).
\]

Remark 5.3. The first proof of Theorem 5.2 is a straightforward application of Theorem 3.3 and two standard facts:

(1) when \(R\) is Gorenstein there is a natural isomorphism of graded \(R\)-modules

\[
\text{Ext}_R(M, N) \cong \text{Ext}_R(N^\vee, M^\vee)
\]

for each \(M\) and \(N\) in \(D^f(R)\);

(2) when \(R\) is complete intersection

\[
\text{cx}_R(X, Y) \leq \text{cx}_R(M, N)
\]

whenever \(X\) is in \(\text{thick}_{D^f(R)}(M)\) and \(Y\) is in \(\text{thick}_{D^f(R)}(N)\) (see [2, 5.6] or [14, 4.2.5 & 4.2.9]).

First proof of Theorem 5.2. From Remark 5.3(1) it follows easily that

\[
\text{cx}_R(M, N) = \text{cx}_R(N^\vee, M^\vee).
\]

Using Theorem 3.3, we obtain \(M^\vee\) is an object of \(\text{thick}_{D^f(R)}(M)\) and \(N^\vee\) is an object of \(\text{thick}_{D^f(R)}(N)\). So Remark 5.3(2) establishes the inequality

\[
\text{cx}_R(M, N) = \text{cx}_R(N^\vee, M^\vee) \leq \text{cx}_R(N, M).
\]

By symmetry the result follows. 

Remark 5.4. As discussed in the introduction, the theme of [4] is to deduce homological results over \(R\), when \(R\) is complete intersection, using the bridge

\[
\text{jt}: D^f(R) \to D^f(K^R) \xrightarrow{\cong} D^f(\Lambda)
\]

from 1.4. However, in [4, 8.9] it is remarked that the authors did not see how to deduce Theorem 5.2 from studying this bridge. The second proof of Theorem 5.2, given below, shows that one can in fact arrive at the symmetry of complexity over the complete intersection \(R\) as a direct consequence of the symmetry of complexity over \(\Lambda\).
Second proof of Theorem 5.2. Assume $R$ is complete intersection.

Observe that

$$\text{Ext}_R(M, tN) \cong \text{Ext}_{K_R}(tM, tN) \cong \text{Ext}_A(jtM, jtN)$$

where the first isomorphism is adjunction and the second one uses that $j$ is an equivalence. Also, by \cite[4.2.7]{15}

$$\text{cx}_R(M, N) = \text{cx}_R(M, tN),$$

and so combining this with the isomorphisms above we have

(4) $$\text{cx}_R(M, N) = \text{cx}_A(jtM, jtN).$$

Similarly, it follows that

(5) $$\text{cx}_R(N, M) = \text{cx}_A(jtN, jtM).$$

Note \cite[5.3]{4} established

$$\text{cx}_A(jtM, jtN) = \text{cx}_A(jtN, jtM);$$

this equality along with the ones in (4) and (5) establish $\text{cx}_R(M, N) = \text{cx}_R(N, M)$, as claimed.
