Superfluidity or supersolidity as a Consequence of Off-diagonal Long-range Order

Yu Shi
Center for Advanced Study, Tsinghua University, Beijing 100084, China

We present a general derivation of Hess-Fairbank effect or nonclassical rotational inertial (NCRI), i.e. the refusal to rotate with its container, as well as the quantization of angular momentum, as consequences of off-diagonal long-range order (ODLRO) in an interacting Bose system. Afterwards, the path integral formulation of superfluid density is rederived without ignoring the centrifugal potential. Finally and in particular, for a class of variational wavefunctions used for solid helium, treating the constraint of single-valuedness boundary condition carefully, we show that there is no ODLRO and, especially, demonstrate explicitly that NCRI cannot be possessed in absence of defects, even though there exist zero-point motion and exchange effect.

I. INTRODUCTION

It was first suggested by London that the ability of liquid $^4$He II to flow through narrow capillaries without apparent friction is a consequence of Bose-Einstein condensation (BEC). The concept of BEC was later generalized by Penrose and Onsager to be applicable to interacting particles. It was further generalized and systematically investigated by Yang, as the notion of off-diagonal long-range order (ODLRO). Now it is known that the no-friction behavior in narrow capillaries is only one of several phenomena of superfluidity. As elaborated by Leggett, the most basic manifestation of superfluidity is the Hess-Fairbank effect, which was also called “nonclassical rotational inertial” (NCRI) by Leggett. This refers to the refusal of the system to rotate with its container, when its angular velocity is sufficiently low. It is the counterpart of the Meissner effect of superconductivity. Furthermore, the quantization of angular momentum of the superfluid in the rotating container is the counterpart of the magnetic flux quantization in a superconductor.

In the case of superconductivity, the demonstration of Meissner effect and the magnetic flux quantization, as consequences of ODLRO, was made by Yang and by Sewell and Nieh et al. in a more recent alternative approach. Bloch discussed the relation between superconducting persistent current and ODLRO. In the case of superfluidity, Kohn and Sherrington derived the Hess-Fairbank effect as a consequence of ODLRO by using a sophisticated hierarchy of equations of thermal Green functions. For a noninteracting Bose gas and a Gross-Pitaevskii system, Leggett made a clear-cut demonstration of Hess-Fairbank effect and quantization of angular momentum as consequences of BEC. Earlier, in an extremely thorough and insightful discussion, Leggett pointed out that a sufficient condition of superfluidity is a certain topological connectedness property of the many-body wavefunction, and that at least for zero temperature, ODLRO gives rise to this connectivity and thus superfluidity, but for a finite temperature, whether ODLRO is sufficient for superfluidity in general is not conclusive.

Moreover, Leggett established, from the point of view of connectivity of wavefunction, that BEC and NCRI behavior can in principle also be exhibited by a solid $^4$He. Recently, Kim and Chan clearly observed NCRI-like behavior in bulk solid $^4$He in an annulus channel shortly after an earlier such observation in solid $^4$He confined in porous Vycor glass. But a consensus on its origin is yet to be reached. The earliest predictions on supersolidity, i.e. superfluid behavior in a solid, were based on BEC of defect states. But the concentration of zero-point vacancies is less than $10^{-6}$ according to the experimental results. Thus an important question is whether it is possible for a pure commensurate sample of solid $^4$He, i.e. without vacancies or interstitials, to become a supersolid. Negative answers were given recently in a path integral Monte Carlo calculation of exchange frequencies in bulk $^4$He and in a general argument about superfluidity density.

Thus from both the fundamental point of view and the perspective of understanding supersolid behavior, it appears still interesting to make a general derivation of the Hess-Fairbank effect and quantization of angular momentum as clear consequences of ODLRO for an interacting Bose system in a rotating container. In this paper, we first make such a derivation. Afterwards, for a reason explained below, we rederive the superfluid density in the path integral formulation, which is the very basis of the analyses of solid $^4$He in Ref. and Ref. Finally, we consider the trial wavefunctions ever used in variational calculations for solid helium, including the Hartree wavefunction, the Hartree-Fock wavefunction and the Nosanow-Jastrow wavefunction. It is shown that there is no ODLRO or BEC in these wavefunctions. Moreover, by examining the dependence of free energy on the rotation velocity of the container, we explicitly demonstrate that a commensurate solid described by such wavefunctions cannot possess NCRI, in absence of vacancies or interstitials, even if there exist zero-point motion and the exchange effect.

Note that the non-superfluidity of the Hartree-Fock wavefunction made up of localized single parti-
The container is at rest. In this frame, the Hamiltonian in the co-rotating frame of reference, in which the wall of the annular container is determined by the minimization of the free energy long ago. Our approach provides an explicit construction of the rotating wavefunction under the constraint of the “single-valuedness boundary condition” (SVBC) as called by Leggett, while keeping the energy the same as that in the static case. To do this, adjustment on the wavefunction needs to be made in the exponentially vanishing regions, indeed as argued by Leggett.

The organization of the paper can be clearly seen in the section titles.

II. HAMILTONIANS AND FREE ENERGIES IN THE TWO REFERENCE FRAMES

As usual, consider a Bose system in a container rotating with a angular velocity \( \omega \). Thermodynamic equilibrium is determined by the minimization of the free energy in the co-rotating frame of reference, in which the wall of the container is at rest. In this frame, the Hamiltonian is

\[
H = \sum_j \left[ \frac{\mathbf{p}_j \cdot \mathbf{r}_j}{2m} - \frac{1}{2} m (\mathbf{\omega} \times \mathbf{r}_j)^2 + U(\mathbf{r}_j) \right] + \frac{1}{2} \sum_{j \neq k} V_{jk},
\]

(1)

where the notations are standard, \( U \) is the external potential, \( V_{jk} = V(|\mathbf{r}_j - \mathbf{r}_k|) \) is the particle-particle interaction and is rotationally invariant. For basic mechanics and thermodynamics of a rotating body and the application to a Bose system, we refer to the standard texts. But we draw attention to the point that for each particle, the radius vector \( \mathbf{r}_j \), the canonical momentum \( \mathbf{p}_j \), and the angular momentum \( \mathbf{l}_j = \mathbf{r}_j \times \mathbf{p}_j \) are respectively the same in the laboratory frame and in the co-rotating frame. It is for this reason that \( H \) can be re-written as

\[
H = H_{\text{lab}} - \omega \cdot \sum_j \mathbf{l}_j,
\]

where

\[
H_{\text{lab}} = \sum_j \left[ \frac{\mathbf{p}_j^2}{2m} + U(\mathbf{r}_j) \right] + \frac{1}{2} \sum_{j \neq k} V_{jk}
\]

is the Hamiltonian in the laboratory frame. This point is quite delicate in ODLRO study.

For simplicity, as usual, consider a thin cylindrical annular container, with average radius \( R \) and thickness \( d \ll R \) (Fig. 1). The rotation \( \omega \) is, of course, along the cylindrical axis (\( z \) axis). Then the centrifugal potential becomes a \( \omega \)-dependent constant (in the sense that it is independent of the particle configuration), \(- \frac{1}{2} M(\omega R)^2\), where \( M \) is the total mass of the particles.

It is probably useful to make a synopsis here on the free energies in the two reference frames and their relations with the rotational inertial and the superfluid density.

The free energy in the co-rotating frame can be written as

\[
F = F_0 - \frac{1}{2} I_c \omega^2 = a - \frac{1}{2} I \omega^2,
\]

(2)

where \( a \) is a constant, \( I_c = MR^2 \) is the classical rotation inertial,

\[
F_0 \equiv a + \frac{1}{2} (I_c - I) \omega^2.
\]

The total angular momentum is \( \mathbf{L} = \langle \sum_j \mathbf{l}_j \rangle \), hence

\[
L_z = I \omega = -\frac{\partial F}{\partial \omega}.
\]

In the laboratory frame, the free energy is

\[
F_{\text{lab}} = F + \mathbf{\omega} \cdot \mathbf{L} = F + I \omega^2.
\]

Therefore,

\[
F_{\text{lab}} = F_{\text{lab},0} + \frac{1}{2} I_c \omega^2 = a + \frac{1}{2} I \omega^2,
\]

where

\[
F_{\text{lab},0} \equiv a - \frac{1}{2} (I_c - I) \omega^2.
\]

Consistently, one also has

\[
L_z = I \omega = \frac{\partial F_{\text{lab}}}{\partial \omega},
\]

\[
I = -\frac{\partial^2 F}{\partial \omega^2} = \frac{\partial^2 F_{\text{lab}}}{\partial \omega^2}.
\]

For a normal system, \( I = I_c \), thus \( F_0 = F_{\text{lab},0} = a \). If \( F_0 \) or, equivalently, \( F_{\text{lab},0} \) depends on \( \omega \), then the system is a superfluid, with NCRI. The superfluid fraction is

\[
\frac{\rho_S}{\rho} = 1 - \frac{I_c - I}{I_c \omega^2} = \frac{1}{I_c} \frac{\partial^2 F_{\text{lab},0}}{\partial \omega^2},
\]

where \( \rho_S \) and \( \rho \) are the superfluid density and the total fluid density, respectively.

It should be noted that in equilibrium, it is \( F \), not \( F_{\text{lab}} \), that is related to the partition function \( Q \) as \( F = -kT \ln Q \).
III. A DERIVATION OF NCRI FROM ODLRO

Now we make a general derivation that if the system possesses ODLRO, then $F_0$ in Eq. (2) depends on $\omega$. We use an approach similar to Yang’s treatment of superconductivity in a magnetic field.\footnote{Yang, C.N., 1957, Phys. Rev. 108, 1306.}

Using the cylindrical coordinates $(z, r, \theta)$ and considering the geometry, the Hamiltonian \footnote{We use an approach similar to Yang's treatment of superconductivity in a magnetic field.} can be simplified as

$$H = H_0 - \frac{1}{2} M\omega^2 R^2,$$  \hspace{1cm} (3)

with

$$H_0 = \sum_j \left( \frac{p_{\theta j}^2 - m\omega R^2}{2m} \right) + \frac{1}{2} \sum_{j \neq k} V_{jk} + NU(R),$$

where $p_{\theta j} = (1/R)\partial/\partial \theta_j$. The radial momentum $p_{r j} = \partial/\partial r_j$ is neglected because $d \ll R$. An eigenfunction $\psi_\alpha$ of $H$ satisfies

$$H\psi_\alpha = E_\alpha\psi_\alpha,$$

and the periodic boundary condition, or SVBC,

$$\psi_\alpha(\theta_j + 2\pi, \{\theta_i \neq j\}) = \psi_\alpha(\theta_j, \{\theta_i \neq j\})$$  \hspace{1cm} (4)

due to the cylindrical geometry.

Because $-M\omega^2 R^2/2$ is a constant for a given $\omega$, we only need to consider $H_0$, whose eigenfunctions are completely the same as those of $H$, i.e.

$$H_0\psi_\alpha = E_\alpha\psi_\alpha,$$  \hspace{1cm} (5)

where $E_\alpha = E_\alpha + M\omega^2 R^2/2$.

By a “gauge” transformation

$$\psi_\alpha = \psi_\alpha' \exp\left(\frac{i m\omega R \sum_j \theta_j}{\hbar}\right),$$

$\psi_\alpha'$ satisfies

$$H_0'\psi_\alpha' = E_\alpha'\psi_\alpha',$$  \hspace{1cm} (6)

where

$$H_0' = \sum_j \left( \frac{p_{\theta j}^2 - m\omega R^2}{2m} \right) + \frac{1}{2} \sum_{j \neq k} V_{jk} + NU(R).$$

The angular boundary condition becomes

$$\psi_\alpha(\theta_j + 2\pi, \{\theta_i \neq j\}) = e^{-\frac{2\pi i m\omega R}{\hbar}}\psi_\alpha(\theta_j, \{\theta_i \neq j\}).$$  \hspace{1cm} (7)

Now consider the un-normalized density matrix

$$\rho_{dm} = e^{-\frac{\hbar \theta}{4\pi}}.$$

by tracing over all but one particle, one obtains the (un-normalized) one-particle reduced density matrix $\rho_1$.

The problem determined by $H_0$ together with SVBC is equivalent to the description in terms of $H'_0$ together with Eq. (7). From the $\omega$-independence of $H'_0$ and the boundary condition (7), one knows that

$$\langle \theta' + 2\pi | \rho_1 | \theta \rangle = \langle \theta' | \rho_1 | \theta - 2\pi \rangle = e^{-\frac{2\pi i m\omega R}{\hbar}} \langle \theta' | \rho_1 | \theta \rangle.$$  \hspace{1cm} (7)

We can now apply Yang’s method to the current problem. Without ODLRO, $\rho_1$ is vanishingly small except in the regions around $\theta = \theta \pm 2m\pi$, where $n = 0, 1, \cdots$. As indicated by Eq. (7), the values of $\rho_1$ in two neighboring regions only differ by a phase factor $e^{\pm \frac{2\pi i m\omega R}{\hbar}}$.

With ODLRO, these regions with nonvanishing $\rho_1$ merge into each other, and $\rho_1$ is nonvanishing everywhere. The above phase relation remains.

Furthermore, with ODLRO, Eq. (7) implies that the dependence of $\langle \theta' | \rho_1 | r \rangle$ on $r - r'$ must vary as $\omega$ varies. Consequently, $Q(H_0)$ and thus $F_0$ also vary with $\omega$, as $Q(H_0) = Tr \rho_1$ and $F_0 = -kT\ln Q(H_0)$. This proves that ODLRO gives rise to superfluidity or NCRI.

IV. QUANTIZATION OF ANGULAR MOMENTUM

We now demonstrate the quantization of angular momentum as a consequence of ODLRO, by employing the method of Bloch in discussing superconducting persistent current,\footnote{Leggett, J., 1979, Phys. Rev. Lett. 42, 538.} and also as a generalization of an argument by Leggett.\footnote{As above, the angular momentum and momentum are, respectively, the same in the laboratory frame and in the co-rotating frame. But for convenience, here we use the co-rotating frame.}

Consider the one-particle reduced density matrix with $r$ and $z$ coordinates integrated over,

$$\langle \theta' | \rho_1 | \theta \rangle = \int dr \int dz \langle r, \theta', z | \rho_1 | r, \theta, z \rangle,$$

and its Fourier transformation

$$\langle \theta' | \rho_1 | \theta \rangle = \frac{1}{2\pi} \sum_{l, l'} e^{i(l\theta - l'\theta')} \langle l' | \rho_1 | l \rangle,$$  \hspace{1cm} (8)

where $l$ and $l'$ represent angular momenta. Its normalization is

$$\int \langle \theta | \rho_1 | \theta \rangle d\theta = \sum_l \langle l | \rho_1 | l \rangle = N.$$

Conservation of angular momentum in the $z$ direction implies that $\langle l' | \rho_1 | l \rangle = 0$ for $l' \neq l$.

The total angular momentum, along the $z$ direction, for the system under consideration can be given as

$$L_z = \sum_l l \langle l | \rho_1 | l \rangle.$$  \hspace{1cm} (9)
In the Hamiltonian in Eq. (3), \( p_{0j} \) can be substituted as \( l_{zj}/R \), where \( l_{zj} \) is the \( z \)-component angular momentum operator of the \( j \)-th particle. Thus \( H \) depends on single particle angular momentum operators through the kinetic term

\[
\sum_j (l_{zj} - m\omega R^2)^2/(2mR^2).
\]

Define \( \tilde{l} = l - m\omega R^2 \). In Eq. (9), if the summation can be replaced as an integral, then one can substitute \( l \) as \( \tilde{l} + m\omega R^2 \) and replace the integral over \( l \) as that over \( \tilde{l} \). Consequently one obtains

\[
L_z = Nm\omega R^2,
\]

which must be vanishing. Therefore

\[
\big| \langle \tilde{l} \rangle \big| \approx \frac{1}{2} \big| \rho N \big| ( ||\rho|l|| \rangle \big| \approx 0, \big| \big| \tilde{l} \big| \big| \big| \rangle \big| \approx l_0, \text{ then one cannot replace the summation as an integral.}
\]

For such a probability distribution caused by ODLRO, \( \langle ||\rho|l|| \rangle \rangle = N_0 \) for \( l = l_0 \), where \( N_0 \) is of the same order of magnitude as \( N \), while \( \langle ||\rho|l|| \rangle \rangle \) for other values of \( l \) are negligible. Thus the total angular momentum is quantized as

\[
L_z \approx N_0 l_0,
\]

with \( l_0 \) determined by minimizing the Hamiltonian. When \( \omega \) is sufficiently small, \( l_0 = 0 \), i.e. the system exhibits Hess-Fairbank effect. When \( \omega \) is finite, \( l_0 \) is finite, but \( N_0 l_0 \) is less than \( Nm\omega R^2 \).

V. RE-DERIVATION OF SUPERFLUID DENSITY IN PATH INTEGRAL FORMALISM

The analyses on solid \( ^4\text{He} \) in Refs.\( ^1,17 \) were based on an elegant path integral formulation of superfluid density in a rotating annulus\( ^22 \) with the same geometry as in our consideration above. It was derived by neglecting the centrifugal potential. We believe that the centrifugal potential cannot be neglected. As this formulation of superfluid density is very important and widely used, it may be worthwhile to rederive it without neglecting the centrifugal potential. It turns out that it nicely remains the same, although the centrifugal potential is added to the free energy. But it seems that this is known only after it is checked, so it is reported here.

We re-write the Hamiltonian in the rotating frame, already given in Eq. (1), as

\[
H = \sum_j \frac{(p_j - m\omega)^2}{2m} - \frac{1}{2} Nmv^2 + U + V,
\]

where, to follow Ref.\( ^22 \), the rotational velocity \( \omega R \) is denoted as \( v \). The external potential and the interaction terms are schematically denoted as \( U \) and \( V \) respectively. \( U \) is absent in Ref.\( ^22 \), but its addition does not change the equations concerned. This Hamiltonian determines the density matrix \( \rho_{dn} \) and the statistical distribution.

One obtains\( ^22 \)

\[
\frac{\rho N}{\rho} Nmv = \frac{Tr(p \rho_{dn})}{Tr(\rho_{dn})},
\]

where \( \rho N \) is the normal fluid density, \( P = \sum_j p_j \) is the total momentum. This identity is obtained by considering the momentum in the laboratory frame, as \( v \) is the container velocity in the laboratory frame. Again, note that the canonical momentum is the same in the laboratory and in the co-rotating frames, while it reduces to the kinematic momentum in the laboratory frame.

Because

\[
P = -\frac{\partial H}{\partial \nu},
\]

Eq. (11) can be re-written as

\[
\frac{\rho N}{\rho} Nmv = -\frac{\partial F}{\partial \nu},
\]

where \( F = -kT \ln[Tr(\rho_{dn})] \) is the free energy in the co-rotating frame. Therefore the superfluid fraction is

\[
\frac{\rho_s}{\rho} = 1 + \frac{\partial \left( \frac{F}{N} \right)}{\partial \left( \frac{1}{2}mv^2 \right)}.
\]

Thus the free-energy change due to the rotation of the container, up to the order of \( v^2 \), is

\[
\frac{\Delta F}{N} = \frac{mv^2}{2} \left( \frac{\rho_s}{\rho} - 1 \right),
\]
from which it can be confirmed that the centrifugal potential $mv^2/2$ indeed cannot be ignored, since it is no less than the other term $(\rho S/\rho)mv^2/2$.

In the path integral calculation,

$$e^{-\beta \Delta F} = \frac{\int \rho_{dm}(\mathbf{X}, \mathbf{X}; \beta; \mathbf{v})d\mathbf{X}}{\int \rho_{dm}(\mathbf{X}, \mathbf{X}; \beta; \mathbf{v} = 0)d\mathbf{X}},$$

where $\mathbf{X}$ represents the configuration of the particles. The “gauge term” $-m\mathbf{v}$ in the kinetic energy term can be transformed away, by adding, in the density matrix elements, a phase factor in winding the periodic system, like in Eqs. 6 and 7. Consequently, one can replace $\rho_{dm}(\mathbf{X}, \mathbf{X}; \beta; \mathbf{v})$ as the density matrix $\rho_{dm}(\mathbf{X}, \mathbf{X}; \beta; \mathbf{v})$ corresponding to the Hamiltonian without the “gauge term”, while multiplying it by a phase factor due to the total paths $\mathbf{W} \mathbf{L}$ of the $N$ particles winding around the system, where $\mathbf{W}$ is the winding number.

$$\rho_{dm} = \exp(-\beta \hat{H}),$$

where $\hat{H} = H(\mathbf{v} = 0) - Nmv^2/2$. $H(\mathbf{v} = 0)$ is just $H_0$ in Sec. III. We obtain

$$e^{-\beta \Delta F} = \langle e^{i\frac{\pi}{N} \mathbf{v} \mathbf{W} \mathbf{L} e^{\beta \Sigma Nmv^2}},$$

where the average that of the density matrix with $\mathbf{v} = 0$. Consequently, up to the order of $v^2$, we have

$$\Delta F = N\frac{mv^2}{2} \left( \frac{m(W^2)\mathcal{L}^2}{3\hbar^2N} - 1 \right),$$

which, together with Eq. 13, yields

$$\frac{\rho S}{\rho} = \frac{m(W^2)\mathcal{L}^2}{3\hbar^2N},$$

which is the same as that given in Ref. 22. They remain the same even if $v$ is not a small quantity, for the reason is that $v$ is independent of the particle configuration.

VI. NO ODLRO IN NOSANOW-JASTROW WAVEFUNCTIONS

Now we turn our attention to solid $^4$He. For a commensurate solid at rest, each atom occupies a lattice site. Because of quantum mechanical zero-point motion, which is large in solid helium, around the neighborhood of each lattice site, there is a finite region in which the wavefunction is nonvanishing. With the exchange effect put aside first, the wavefunction is localized around each lattice site, i.e. it decays from the maximum at the lattice site. Let’s denote the wavepacket of atom $i$ as $w(\mathbf{r}_i - \mathbf{Q}_i)$, where $\mathbf{r}_i$ is the actual position of the atom, $\mathbf{Q}_i$ represents a lattice site fixed in the solid. The Hartree approximation of the wavefunction of the solid helium is the product of these single-atom wavefunctions, i.e.,

$$\Phi_H = \prod_{i=1}^{N} w(\mathbf{r}_i - \mathbf{Q}_i),$$

which was indeed used in the earliest (unsatisfactory) variational calculations of solid helium. Later works, starting by Nosanow took into account the two-particle short-range correlation by multiplying the Hartree-wavefunction by the Jastrow factor.

To account for the exchange effect due to overlap between neighboring single-particle wavepackets, one also needs to consider the wavefunction symmetrized over all the atoms; the detailed nature of the exchange effect is then determined by the Hamiltonian. With symmetrization, the Hartree approximation is improved to Hartree-Fock approximation,

$$\Phi_{HF} = \frac{1}{\sqrt{N!}} \sum_{P} P \prod_{i=1}^{N} w(\mathbf{r}_i - \mathbf{Q}_i),$$

where $P$ represents $N!$ permutations of the $N$ lattice sites $\{\mathbf{Q}_i\}$. The symmetrization can be made on either the particle positions $\{\mathbf{r}_i\}$ or the lattice sites $\{\mathbf{Q}_i\}$. We choose the latter for easier manipulation below.

The symmetrized Nosanow-Jastrow wavefunction is

$$\Phi_{SNJ} = K \sum_{P} \prod_{i=1}^{N} w(\mathbf{r}_i - \mathbf{Q}_i) \prod_{k \neq j} f_{jk},$$

where $K$ is the normalization constant,

$$f_{jk} \equiv f(-u(\mathbf{r}_j - \mathbf{r}_k))$$

is the Jastrow (or, to be historically precise, Bijl-Dingle-Jastrow) function. $f(-u(r))$ attains a maximum larger than 1 at a certain distance $r_0$, and it is constrained to be $f \to 0$ as $r \to 0$, and $f \to 1$ as $r \to \infty$ or $r > \sigma$ where $\sigma$ is a parameter. Note that $\prod_j \prod_{j<k} f_{jk}$ is automatically symmetric for all particles.

Our consideration is about a thin cylindrical bulk, $\mathbf{r}_i = (\mathbf{R}, \mathbf{R}\theta_i, z_i)$. Especially, the periodic boundary condition in coordinate $\theta$ should be taken into account in an essential way. It implies that the Wannier-like function $w$ must be of the form

$$w(\mathbf{r} - \mathbf{Q}) = A \sum_{\gamma = -\infty}^{\infty} \bar{w}(\mathbf{r} - \mathbf{Q} - \gamma \mathbf{G}),$$

where $A$ is the normalization constant, $\mathbf{G} = 2\pi \mathbf{R} \hat{\theta}$ represents the circumference, $\gamma$ represents integers, $\bar{w}$ is the (real) Wannier-like function for the infinite interval. Each $\bar{w}$ extends over a finite range, much smaller than the system size, but finite overlap is allowed. $\pm \infty$ in the summation can be understood as two bounds which can be arbitrarily large. Thus

$$\bar{w}(\mathbf{r}) \approx \bar{w}(\mathbf{r} - \mathbf{S}) \approx \bar{w}^2(\mathbf{r}) \exp(-|\mathbf{S}|/c),$$

where $\mathbf{S}$ is an arbitrary vector, $c$ is a length scale less than the lattice constant. Consequently, the normalization constant $A$ in Eq. 14 is $A \approx (\sum_{\gamma, \gamma'} \exp(-|\gamma - \gamma'|(\mathbf{G}/c))^{-1/2}.$
Moreover, it can be found that
\[ w(r) w(r - S) \leq \bar{w}^2(r) \exp(-|S\theta|/c), \tag{19} \]
where \( S\theta \) is the \( \theta \) component of \( S \) modulo \( \pm G \) such that \( |S\theta| \leq G/2 \), i.e., \( |S\theta| \) is the shortest \( \theta \)-component of the distance between the two physical points represented by \( r \) and \( r - S \).

We now set out to show that there is no ODLRO or BEC in \( \Phi_H \) or \( \Phi_{HF} \) or \( \Phi_{SNJ} \), by examining the one-particle reduced density matrix
\[
\rho_1(r, r') = N \int dr_2 \cdots dr_N \Phi(r, r_2, \ldots, r_N) \Phi(r', r_2, \ldots, r_N)
\]
for the ground state wavefunction \( \Phi \) of the form of \( \Phi_H \) or \( \Phi_{HF} \) or \( \Phi_{SNJ} \).

Though trivial, it is instructive to first consider \( \Phi_H \). It is straightforward to integrate out \( r_2, \ldots, r_N \), and obtain
\[
\rho_1(r, r') = N \bar{w}(r - Q_1) w(r' - Q_1),
\]
for which Eq. (19) directly leads to
\[
\rho_1(r, r') \leq N \bar{w}^2(r) \exp(-|x - x'|/c), \tag{20}
\]
where \( x = R\theta \) denotes the \( \theta \)-component of \( r \). Of course, \( \bar{w}^2(r) \leq 1 \). Thus \( \rho_1(r, r') \to 0 \) as \( |x - x'| \) approaches the system size, i.e. there is no ODLRO or BEC in \( \Phi_H \).

Now consider the Hartree-Fock wavefunction \( \Phi_{HF} \). In the expansion of \( \rho_1 \), suppose the lattice sites in the first \( \Phi \) are denoted as \( \{ Q_i \} \) while those in the second \( \Phi \) are denoted as \( \{ Q'_i \} \). The exponential decay of the overlap between single-particle wavefunctions, Eq. (19), implies that among the \( (N!)^2 \) terms in the expansion of \( \rho_1 \), one can neglect each term in which \( Q_i \neq Q'_i \), for at least one of \( i = 2, \ldots, N \). Consequently, there are only \( N! \) remaining terms, in each of which \( Q_i = Q'_i \) for \( i = 1, \ldots, N \), then \( r_2, \ldots, r_N \) are subsequently all integrated out. This \( N! \) is cancelled by the \( N! \) in the normalization constant. Hence, for large \( |x - x'| \), \( \rho_1(r, r') \) for \( \Phi_{HF} \) behaves in the same way as for the Hartree wavefunction, given in Eq. (20). This proves there is no ODLRO or BEC in \( \Phi_{HF} \) either.

The argument can be extended to symmetrized Nosanow-Jastrow wavefunction \( \Phi_{SNJ} \), which can be rewritten as
\[
\Phi_{SNJ} = K \sum_P P \prod_{i=1}^N [w(r_i - Q_i) \prod_{j<i} f_{ji}], \tag{21}
\]
where \( P \) represents the permutation of the \( N \) lattice sites \( \{ Q_i \} \). \( \prod_{i<j} f_{ji} \) is a function of \( r_1, \ldots, r_i \), and reduces to 1 for \( i = 1 \). For each term in the expansion of \( \rho_1 \), consider \( w(r_i - Q_i) w(r_i' - Q_i') (\prod_{j<i} f_{ji})^2 \leq \bar{w}^2(r) \exp(-|Q_i\theta - Q'_i\theta|/c)(\prod_{j<i} f_{ji})^2 \), where \( Q_i\theta \) is the \( \theta \)-component of \( Q_i \). It can be seen that the short-range Jastrow factor does not change the nature of long-range exponential decay. Therefore, the cross terms, in which \( Q_i \neq Q'_i \) for at least one of \( i = 1, \ldots, N \), exponentially decay, and are negligible in comparison with the remaining terms. Consequently,

\[
\rho_1(r_i, r_i') \approx \frac{N w(r_i - Q_i) w(r_i' - Q_i) (\prod_{j<i} f_{ji}) (\prod_{i<j} f_{ji})^2 f_{i1} f_{i'i}}{\prod_{i+j} w^2(r_i - Q_i) (\prod_{i<j} f_{ji})^2 dr_i},
\]
\[
\leq N \bar{w}^2(r_i) e^{-|x_i - x_i'|/c} \prod_{j>i} \int w^2(r_j - Q_i) (\prod_{i<j} f_{ji})^2 f_{i'1} f_{i'i} dr_i,
\]
where \( f_{i'1} \equiv f(-w(r_i' - r_i)) \). The fraction factor in (22) must be bounded by a finite number. Clearly, \( \rho_1(r, r') \) tends to exponentially vanish as \( |x - x'| \) approaches the system size. Thus there is no ODLRO or BEC in \( \Phi_{SNJ} \) either. It can be seen that our argument is not disrupted by the thermodynamic limit \( N \to \infty \).

Furthermore, the argument can be straightforwardly generalized to a finite temperature, in which each energy eigenfunction is of the form of \( \Phi_H \) or \( \Phi_{HF} \) or \( \Phi_{SNJ} \). The finite-temperature density matrix is the thermal average of the density matrices of the eigenfunctions. For an infinite sample, \( w \) would simply be \( \bar{w} \), the conclusion of no ODLRO can still be obtained, in a simpler way.

Therefore, although there is ODLRO or BEC in the Jastrow wavefunction alone, which describe liquid helium, they are dominated by the localized one-particle wavefunctions. This is a difference between liquid and solid. The argument extends that of Penrose and Onsager about no BEC in a solid\(^2\) to the case with zero-point motion, exchange effect, as well as short-range correlation.

VII. NO SUPERSOLIDITY IN NOSANOW-JASTROW WAVEFUNCTIONS

As ODLRO is a sufficient condition of NCRI, it is not redundant to demonstrate that there is no NCRI in \( \Phi_H \) or \( \Phi_{HF} \) or \( \Phi_{SNJ} \), as we now explicitly do in the following. We adapt the method of Kohn used in discussing electronic insulating state\(^2\). Recall that the eigenfunctions and energy spectrum is determined by \( H_0 \), as in Eq. (5). The idea is the follow-
ing. For every eigenfunction \( \Psi_\alpha(\omega = 0) \) of \( H_0(\omega = 0) \), where \( \alpha \) is the index for different eigenfunctions, be it of the form of \( \Phi_H \) or \( \Phi_{HF} \) or \( \Phi_{SNJ} \), we show that there is a corresponding eigenfunction \( \Psi_\alpha(\omega \neq 0) \) of \( H_0(\omega \neq 0) \), and that its eigenvalue remains the same as that of \( H_0(\omega = 0) \) for \( \Psi_\alpha(\omega = 0) \).

\( H_0(\omega \neq 0) \) is simply related to \( H_0(\omega = 0) \) by a “gauge” transformation, but one should be cautioned by the requirement of the SVBC.\(^7\) In an infinite interval, for a localized single-particle eigenfunction \( \bar{\psi}(r) \) of a single-particle Hamiltonian, the correct eigenfunction wavefunction for \( \omega \neq 0 \) is

\[
\bar{\psi}'(\omega; r) = \bar{\psi}(r) \exp\left(\frac{i m \omega x}{\hbar}\right),
\]

where, as above, \( x = R \theta \).

Therefore, for a many-particle eigenfunction \( \Psi_\gamma(\omega = 0) \) of \( H_0(\omega = 0) \), given by \( \Phi_H \) or \( \Phi_{HF} \) or \( \Phi_{SNJ} \), one may construct the corresponding eigenfunction \( \Phi_\alpha(\omega \neq 0) \) of \( H_0(\omega \neq 0) \) in a similar way, by replacing every single-particle \( \bar{\psi}(r) \) as \( \bar{\psi}'(r) \). The presence of Jastrow factor does not affect this.

On the other hand, by using Eq. (17), \( \Psi_\alpha(\omega = 0) \) can be written as

\[
\Psi_\alpha(\omega = 0) = A^N \sum_{\Gamma=-\infty}^{\infty} \Phi_{\Gamma}(\{r_i\}),
\]

where \( \Phi_{\Gamma} \) is obtained from \( \Phi \) by shifting the centers of the single-particle wavepackets \( \bar{\psi} \) from \( \{Q_i\} \) to \( \{Q_i + \gamma_i G\} \), with \( \sum_i \gamma_i = \Gamma \); here \( \Phi \) is of the form of \( \Phi_H = \prod_{i=1}^{N} \bar{\psi}(r_i - Q_i) \), or \( \Phi_{HF} = \frac{1}{\sqrt{N!}} \sum_p P \prod_{i=1}^{N} \bar{\psi}(r_i - Q_i) \), or \( \Phi_{SNJ} = K \sum_p P \prod_{i=1}^{N} \bar{\psi}(r_i - Q_i) \prod_i \prod_{j<k} f_{jk} \).

Following the argument in Ref.\^7, using the exponential decay of the overlap as shown in Eq. (13), and very similar to the argument in last section, it can be shown that for \( \Gamma \neq \Gamma' \) and arbitrary \( \alpha \) and \( \alpha' \), \( \Phi_{\alpha,\Gamma} \) and \( \Phi_{\alpha',\Gamma'} \) have exponentially vanishing overlap and give vanishing matrix element for an arbitrary one-particle position operator.

Consequently, it can be found that the corresponding eigenfunction of \( H_0(\omega) \), satisfying the SVBC, is

\[
\Psi_\alpha(\omega) = \sum_{\Gamma=-\infty}^{\infty} \Phi_{\alpha,\Gamma}(\{r_i\}) \exp\left[\frac{i m \omega R}{\hbar} (\sum_j \theta_j - 2 \pi \Gamma)\right].
\]

Because of exponentially vanishing overlap between \( \Phi_{\alpha,\Gamma} \) with different values of \( \Gamma \), it is clear that

\[
H_0(\omega) \Psi_\alpha(\omega) = E_\alpha(\omega) \Psi_\alpha(\omega).
\]

with

\[
E_\alpha(\omega) = E_\alpha(\omega = 0).
\]

It is thus proved that every eigenvalue \( E_\alpha(\omega) \) of \( H_0(\omega) \) is independent of \( \omega \). Interestingly, the argument has gone through even in presence of the Jastrow factors.

In fact, the explicit construction of the wavefunction here confirms the principle, established by Leggett\^7, that the system is non-superfluid if for the wavefunction of the rotating system, the SVBC can still be satisfied without causing the energy to be increased by the rotation. Leggett already applied this principle to the Hartree-Fock wavefunction.

Therefore, for a commensurate quantum solid described by Hartree or Hartree-Fock or Nosanow-Jastrow wavefunction, even though the exchange effect, large zero-point motion and short-range correlation are taken into account, the free energy is of the form of Eq. (2), with \( F_0 \) independent of \( \omega \). This indicates that it cannot be a supersolid.

In our argument, the localized single-particle wavefunctions play a crucial role. Obviously, the situation would be different when there exist vacancies or interstitials or both, which makes the wavefunctions extended. The recent experimental result of Kim and Chan poses a significant challenge. The difficulty might be resolved if an extended factor is found in the actual wavefunction.

**VIII. SUMMARY**

To summarize, we have offered some analytic arguments concerning the existence or non-existence of superfluidity or supersolidity behavior. This work might be useful for further investigations on the cause of supersolidity. It might be helpful in supplementing the understanding of the relevant classic literature, and in clarifying which and which specific features are counterparts between superfluidity and superconductivity.

Our argument seems to suggest that ODLRO is indeed generically sufficient for superfluidity even in a finite temperature, a question which seems to have remained not entirely resolved previously.

Our discussions start with a synopsis, in Sec. II, on the Hamiltonians and the free energies in the co-rotating and the laboratory reference frames, as well as their relations with rotational inertial and superfluidity density.

In Secs. III and IV, from the presence of ODLRO, we make a general derivation of the most basic manifestation of superfluidity, namely the Hess-Fairbank effect or NCRI, i.e., the refusal of the Bose system to follow the rotation of the container, by using a method of Yang in treating superconductivity in a magnetic field. We also derive the quantization of angular momentum as a consequence of ODLRO, by borrowing a method of Bloch in studying superconducting persistent current. In Sec. V, we rederive the path integral formulation of the superfluid density without neglecting the centrifugal potential.

In Secs. VI and VII, we consider the variational wavefunctions which have been used in solid helium calculations, namely, the Hartree, the Hartree-Fock and the symmetrized Nosanow-Jastrow wavefunctions. The non-superfluidity in the Hartree-Fock wavefunctions was already noted by Leggett from its disconnectivity\^7. We
show that there is no ODLRO in these trial wavefunctions, for both an infinite sample and that confined in a cylindrical annulus. Moreover, by extending a method originally due to Kohn in discussing electronic insulating states, we explicitly demonstrate that there is no NCRI behavior in a commensurate quantum solid described by those trial wavefunctions, even if there exist large zero-point motion, finite overlap between wavepackets and exchange effect. In this argument, the constraint of SVBC in the angular direction is carefully taken into account. The explicit construction of the wavefunction under the rotation is consistent with the early arguments of Leggett in terms of the connectivity properties. 5,12

Acknowledgments

I am grateful to Professor Sir Tony Leggett for useful comments, as well as hospitality at UIUC in the academic year 2003-2004. I am grateful to Prof. Chen-Ning Yang, Prof. Hwa-Tung Nieh and other faculty members for current hospitality at CASTU. I thank Zheng-Yu Weng, Yong-Shi Wu and Hui Zhai for related conversations.

Erratum
[published as Phys. Rev. B 74, 029901 (E) (2006)]

In Secs. VI and VII, the treatment of symmetrization was inadequate. The problem is fixed below. Our condition is more relaxed: the conclusion holds as far as the overlap between two atomic Wannier functions decays exponentially, with the decay width $c$ much less than the system size, rather than the lattice constant. That is, $\bar{w}(r)\bar{w}(r - S) \approx \bar{w}^2(r)\exp[-|S|/c]$, for the Wannier function $\bar{w}$ in an infinite interval, or $w(r)w(r - S) \leq \bar{w}^2(r)\exp[-|\Theta(S)|/c]$ for the Wannier function $w$ in the annular geometry, where $\Theta(S)$ denotes the shortest $\theta$-component of $S$. As in the original paper, we discuss the annular geometry; the case of infinite interval is simpler.

Consider the Hatree-Fock wavefunction $\Phi_{HF} = D \sum_{P} \prod_{i=1}^{N} w(r_i - Q_{P_i})$, where $P$ represents $N!$ permutations of the $N$ lattice sites $\{Q_i\}$, $\{P_i\}$ are the indices for the $N$ lattice sites in permutation $P$. It can be found that $D = 1/N!\sqrt{\Delta}$, $\Delta = \sum_{P} \prod_{i\neq 1} O_{iP_i}$, where $O_{iP_i} = \int dr_i w(r_i - Q_i)w(r_i - Q_{P_i})$. The one-particle density matrix is thus found to be

$$
\rho_1(r, r') = \frac{N}{N!\Delta} \sum_{P, P'} w(r - Q_{P_i})w(r' - Q_{P'_i}) \prod_{i\neq 1} \int dr_i w(r_i - Q_{P_i})w(r_i - Q_{P'_i})
$$
$$
\leq \frac{N}{N!\Delta} \sum_{P, P'} w(r - Q_{P_i})w(r' - Q_{P'_i}) \prod_{i\neq 1} \exp[-|\Theta(Q_{P_i} - Q_{P'_i})|/c]
$$
$$
\leq \frac{N}{N!\Delta} \sum_{P, P'} \bar{w}^2(r - Q_{P_i}) \exp(-|\Theta(r - r' - Q_{P_i} + Q_{P'_i})|/c) \exp[-|\Theta(Q_{P_i} - Q_{P'_i})|/c]
$$
$$
\leq \frac{N}{N!\Delta} \exp[-|\Theta(r - r')|/c].
$$

In the derivation, the relation $\sum_i Q_{P_i} = \sum_i Q_{P'_i}$ has been used. Therefore, $\rho_1(r, r') \to 0$ as $|\Theta(r - r')|$ approaches the system size. The argument is valid in the thermodynamic limit, as $\Delta$ is of the same order of magnitude of $N!$.

Now consider the symmetrized Nosanow-Jastrow wavefunction $\Phi_{SNJ} = K_N \sum_{P} \prod_{i=1}^{N} w(r_i - Q_{P_i}) \prod_{j<k} f_{j,k}$, where $f_{j,k} \equiv f(|r_j - r_k|)$ is the Jastrow function, $K_N^2 = \sum_{P, P'} \int dr_i \int dr_i \prod_{i\neq 1} \int dr_i w(r_i - Q_{P_i})w(r_i - Q_{P'_i})(\prod_{i<j<k} f_{j,k})^2$. In a way similar to the above derivation for $\Phi_{HF}$, it is found that $\rho_1(r, r') \leq \frac{NK_N^2}{N!\Delta} \sum_{P, P'} w(r - Q_{P_i})w(r' - Q_{P'_i}) \exp(-|\Theta(Q_{P_i} - Q_{P'_i})|/c) \prod_{i\neq 1} \int dr_i \int dr_i \prod_{i\neq 1} f(|r_i - Q_{P_i}|) \prod_{i\neq 1} \int dr_i \int dr_i w^2(r_i - Q_{P_i})(\prod_{1<j<k} f_{j,k})^2 \leq N \exp(-|\Theta(r - r')|/c) F^2 K_N^2 \sum_{P, P'} \prod_{i\neq 1} \int dr_i \int dr_i w^2(r_i - Q_{P_i})(\prod_{1<j<k} f_{j,k})^2$, where $F$ is the maximum value of the Jastrow function. It can be seen that $\rho_1(r, r') \to 0$ as $|\Theta(r - r')|$ approaches the system size, and that the argument is valid in the thermodynamic limit.

Thus it is proved that there is no ODLRO in $\Phi_{HF}$ or $\Phi_{SNJ}$ under the condition stated above. The symmetrization should be dealt with in a similar way in Sec. VII, where it is shown that $\Phi_{\alpha,\Gamma}$ and $\Phi_{\alpha',\Gamma'}$, with $\Gamma \neq \Gamma'$, have exponentially vanishing overlap and give vanishing matrix element for an arbitrary one-particle position operator, which leads to the conclusion of no supersolidity in these wavefunctions.

As noted in Ref. 1, it had been shown previously that there is no ODLRO in Hatree-Fock wavefunctions under the condition that the sum of the overlap integrals between any site and its neighbors is less than unity.\(^2\)

I thank Xin-Cheng Xie for questioning the original treatment of the symmetrization.
