A Classification Approach for Open Manifolds

Jürgen Eichhorn, Greifswald

March 30, 2022

1 Introduction

For closed manifolds there exists an effective highly elaborated classification approach the main steps of which are the Thom–Pontrjagin construction, bordism theory, surgery, Wall groups, the exact sequence of Browder–Novikov–Sullivan–Wall. All this can be expressed in an algebraic language of f. g. $\mathbb{Z}_\pi$, unitary $\mathbb{Z}_\pi$, $\mathbb{Q}_\pi$–modules and their $K$–theory etc. Moreover, there exist many number valued invariants like classical characteristic numbers, signature, higher signature, analytic and Reidemeister torsion, $\eta$–invariants.

For open manifolds, absolutely nothing of this remains, at least at the first glance. We have the following simple

**Proposition 1.1** Let $M^n$ be the set of all smooth oriented manifolds and $V$ a vector space or abelian group. There does not exist a nontrivial map $c : M \to V$ such that

1. $M^n \cong M'$ orientation preserving diffeomorphic implies $c(M) = c(M')$ and
2. $c(M \# M') = c(M) + c(M')$.

**Proof.** Assume at first $M^n \not\cong \Sigma^n$, fix two points at $M^n$, then $M_\infty = M_1 \# M_2 \# \ldots$, $M_i(M, i) \cong M$ has a well defined meaning. We can write $M_\infty = M_1 \# M_{\infty, 2}$, $M_{\infty, 2} = M_2 \# M_3 \# \ldots$ and get

$c(M_\infty) = c(M) + c(M_{\infty, 2}) = c(M) + c(M_\infty)$, $c(M) = 0$.

Assume $M^n = \Sigma^n$, and ord $\Sigma^n = k > 1$ which yields

$$c(\Sigma^n \# \ldots \# \Sigma^n) = k \cdot c(\Sigma^n) = c(S^n), \quad c(\Sigma^n) = \frac{1}{k} c(S^n),$$

$$c(\Sigma^n) = c(\Sigma^n \# S^n) = (1 + \frac{1}{k}) c(S^n), \quad c(S^n) = 2 c(S^n), \quad c(S^n) = 0,$$

$$c(\Sigma^n) = 0.$$  

The only number valued invariant defined for all connected manifolds $M^n$ and known to the author is the dimension $n$. If one characterizes orientabilty / nonorientabity by $\pm 1$ then there are two number–valued invariants. That is all.

Denote by $\mathcal{M}^n([cl])$ the set of all diffeomorphism classes of closed $n$–manifolds. Then we have
Proposition 1.2 \( \# \mathcal{M}^n([cl]) = alef \text{ zero}. \)

**Proof.** According to Cheeger, there are only finitely many diffeomorphism types for \((M^n, g)\) with diam \((M^n, g) \leq D, r_{inj}(M^n, g) \leq i, \) sectional curvature \((M^n, g) \leq K, \) where \(r_{inj}(M^n, g)\) denotes the injectivity radius. Setting \(D_\nu = K_\nu = i_\nu = \nu \) and considering \(\nu \to \infty, \) we count all diffeomorphism types of closed Riemannian \(n\)-manifolds, in particular all diffeomorphism types of closed manifolds.

On the other hand for open manifolds holds

**Proposition 1.3** The cardinality of \(\mathcal{M}([\text{open}])\) is at least that of the continuum, \(n \geq 2.\)

**Proof.** Assume \(n \geq 3, \) \(n\) odd, let \(2 = p_1 < p_2 < \ldots\) be the increasing sequence of prime numbers and let \(L^n(p_\nu) = S^n/Z/p_\nu\) be the corresponding lens space. Consider \(M^n := d_1 \cdot L(p_1) \# d_2 \cdot L(p_2) \# \ldots, d_\nu = 0, 1.\) Then any \(0,1\)-sequence \((d_1, d_2, \ldots)\) defines a manifold and different sequences define non diffeomorphic manifolds. If \(n \geq 4\) is even multiply with \(S^1.\) For \(n = 2\) the assertion follows from the classification theorem in [20].

There are simple methods to construct only from one closed manifold \(M^n \neq \Sigma^n\) infinitely many nondiffeomorphic manifolds. This, proposition 1.3 and other considerations support the naive imagination, that "measure of \(\mathcal{M}([\text{open}]) : \) measure \(\mathcal{M}([cl]) = \infty : 0.\) We understand this as an additional hint how difficult would be any classification of open manifolds.

A certain requirement of what should be the goal of such a classification comes from global analysis. The main task of global analysis is the solution of linear and nonlinear differential equations in dependence of the underlying geometry and topology. Examples for open manifolds are discussed and solved in [8], [9], [10]. To each open manifold there are attached certain functional spaces and admitted maps which enter into the classification should induce maps between the functional spaces, i.e. \(f : M \to M'\) induces a map \((f.sp.)(M') \to (f.sp.)(M).\)

A very simple example shows that this is a reasonable requirement. Consider the diffeomorphism \(f = (tg(\frac{x}{x_1}))^{-1} : [0, \infty[ \to [0, 1[.\) Then \(1 \in L_2([0, 1[)\) but \(1 = f * 1 \notin L_2([0, \infty[).\) Our first conclusion is that one should classify pairs \((M, g)\) and maps should be adapted to the Riemannian metrics under consideration. A pure differential topological classification will be to difficult, not handable and as we shortly indicated, will be less important for applications. Manifolds which appear in applications are endowed with a Riemannian metric. Accepting this, the corresponding algebraic topology should be analytic and simplicial \(L_p^{\text{co}}(\text{co}h)\) homology, bounded (co)homology and others. Consider \((\mathbb{R}^n, g_{\text{standard}}) = (\mathbb{R}^n, dr^2 + r^2 d\sigma_{2n-1}^2)\) and a canonical uniform triangulation \(K_{\mathbb{R}^n}\) of \(\mathbb{R}^n.\) Then \(\overline{H}^{-2}(\mathbb{R}^n) = H^{*,-2}(\mathbb{R}^n) = H^{*,2}(K_{\mathbb{R}^n}) = \overline{H}^{*,-2}(K_{\mathbb{R}^n}) = 0.\)

But if we endow \(\mathbb{R}^n\) with the hyperbolic metric \(g_H = dr^2 + (\sinh r)^2 d\sigma_{2n-1}^2\) then for \(n = 2k \dim \overline{H}^{*,-2}(\mathbb{R}^n, g_H) = \dim H^{*,2}(\mathbb{R}^n, g_H) = \infty\) and for \(n = 2k + 1 \dim \overline{H}^{*,-2}(\mathbb{R}^n, g_H) = 0, \dim H^{k,2}(\mathbb{R}^n, g_H) = \dim H^{k+1,-2}(\mathbb{R}^n, g_H) = \infty.\) Nevertheless \((\mathbb{R}^n, g_{\text{st}})\) and \((\mathbb{R}^n, g_H)\) are canonical isomorphic by the best possible map \(id_{\mathbb{R}^n}.\) We come to our preliminary conclusions,

1. admitted maps \((M, g) \to (M', g')\) must be strongly adapted to \(g, g';\)
2. the classification approach will from a certain step on be connected with spectral properties.
Our approach can be characterized as follows. We first decompose the set of all \((M, g)\)'s into the set of components of a certain uniform structure and then classify (up to a certain amount) the manifolds in the component under consideration, i.e. we have to define two classes of invariants, one for the components and one for the manifolds inside a component. Moreover, we consider several uniform structures which become finer and finer. This implies that the (arc) components become smaller and smaller. Since the whole approach is sufficiently extensive, we can present here only the main steps and sketch some proofs.

The paper is organized as follows. In section 2, we define those uniform structures which consider \((M^n, g)\) only as proper metric spaces. The uniform structures in section 4 take into account the smooth and Riemannian structure of \((M^n, g)\). Section 5 is devoted to bordism theories, adapted in a certain sense to uniform structures under consideration. In the concluding section 6 we define and discuss classes of invariants in the two senses sketched above. Details and complete proofs are contained in [8], [9], [10]. All three papers will be presented for publication.

This presentation is part of a talk given at the conference in honor of V. A. Rohlin, St. Petersburg, August 1999.

## 2 Uniform structures of proper metric spaces

Let \(Z = (Z, d_Z)\) be a metric spaces, \(X, Y \subset Z\) subsets, \(\varepsilon > 0\), define \(U_\varepsilon(X) = \{z \in Z | \text{dist} (z, X) < \varepsilon\}\), analogously \(U_\varepsilon(Y)\). Then the Hausdorff distance \(d_H(X, Y) = d_H^Z(X, Y)\) is defined as

\[
d_H^Z(X, Y) = \inf \{\varepsilon | X \subset U_\varepsilon(Y), Y \subset U_\varepsilon(X)\}.
\]

If there is no such \(\varepsilon > 0\) then we set \(d_H^Z(X, Y) = \infty\), \(d_H^Z\) is an almost metric on the set of all closed subsets, i.e. it has values in \([0, \infty]\) but satisfies all other conditions of a metric. If \(Z\) ist compact then \(d_H^Z\) is a metric on the set of all closed subsets. A metric space \((X, d)\) is called proper if the closed balls \(B_\varepsilon(x)\) are compact for all \(x \in X, \varepsilon > 0\). This implies that \(X\) is separable, complete and locally compact. Any complete Riemannian manifold \((M^n, g)\) is a proper metric space. In the sequel we restrict to proper metric spaces. Let \((X, d_X), (Y, d_Y)\) be metric spaces, \(X \sqcup Y\) their disjoint union. A metric on \(X \sqcup Y\) is called admissible if \(d\) restricts to \(d_X\) and \(d_Y\), respectively. The Gromov–Hausdorff distance \(d_{GH}(X, Y)\) is defined as

\[
d_{GH}(X, Y) = \inf \{d_{H}^{X\sqcup Y}(X, Y) | d \text{ admissible on } X \sqcup Y\}.
\]

Note that the Gromov–Hausdorff distance can be infinite. Gromov defined \(d_{GH}\) originally as

\[
d_{GH}(X, Y) = \inf \{d_{G}^{i(X), j(Y)} | i : X \rightarrow Z, j : Y \rightarrow Z \text{ isometric embeddings into a metric space } Z\}.
\]  

(2.1)

**Lemma 2.1** If \(X\) and \(Y\) are compact metric spaces and \(d_{GH}(X, Y) = 0\) then \(X\) and \(Y\) are isometric.
Proof. This follows from the definition and an Arzela–Ascoli argument. \hfill\Box

Denote by \( \mathcal{M} \) the set of all isometry classes \([X]\) of proper metric spaces \(X\) and \( \mathcal{M}_{GH} = \mathcal{M}/\sim \), where \([X] \sim [Y]\) if \(d_{GH}([X],[Y]) = 0\).

**Proposition 2.2** \(d_{GH}\) defines an almost metric on \( \mathcal{M}_{GH} \).

We denote in the sequel \( X = [X] \) if there does not arise any confusion.

Now we define the uniform structure. Let \( \delta > 0 \) and set

\[
V_\delta = \{(X,Y) \in \mathcal{M}_{GH}^2 | d_{GH}(X,Y) < \varepsilon\}.
\]

**Lemma 2.3** \( \mathcal{L} = \{V_\delta\}_{\delta > 0} \) is a basis for a metrizable uniform structure \( U_{GH}(\mathcal{M}_{GH}) \).

Proof. \( \mathcal{L} \) is locally defined by a metric. Hence it satisfies all desired conditions. \hfill\Box

Let \( \overline{\mathcal{M}}_{GH} \) be the completion of \( \mathcal{M}_{GH} \) with respect to \( U_{GH} \) and denote the metric in \( \overline{\mathcal{M}}_{GH} \) by \( d_{GH} \).

**Lemma 2.4** \( \mathcal{M}_{GH} = \overline{\mathcal{M}}_{GH} \) as sets and \( d_{GH} \) and \( \overline{d}_{GH} \) are locally equivalent.

**Proposition 2.5** \( \mathcal{M}_{GH} = \overline{\mathcal{M}}_{GH} \) is locally arcwise connected.

Proof. We refer to [8] for the proof which is quite elementary but rather lengthy. \hfill\Box

**Corollary 2.6** In \( \mathcal{M}_{GH} \) coincide components and arc components. Moreover, each component is open and \( \overline{\mathcal{M}}_{GH} = \mathcal{M}_{GH} \) is the topological sum of its components,

\[
\mathcal{M}_{GH} = \sum_{i \in I} \text{comp}_{GH}(X_i).
\]

**Proposition 2.7** Let \( X \in \mathcal{M}_{GH} \). Then \( \text{comp}_{GH}(X) \) is given by

\[
\text{comp}_{GH}(X) = \{Y \in \mathcal{M}_{GH} | d_{GH}(X,Y) < \infty\}.
\]

We call a map \( \Phi : X \rightarrow Y \) metrically semilinear if it satisfies the following two conditions.

1. It is uniformly metrically proper, i. e. for each \( R > 0 \) there is an \( S > 0 \) such that the inverse image under \( \Phi \) of a set of diameter \( \leq R \) is a set of diameter \( \leq S \).

2. There exists a constant \( C_\Phi \geq 0 \) such that for all \( x_1, x_2 \in X \)

\[
d_{GH}(\Phi(x_1), \Phi(x_2)) \leq d(x_1, x_2) + C_\Phi.
\]

Two metric spaces \( X \) and \( Y \) are called metrically semilinear equivalent if there exist metrical semilinear maps \( \Phi : X \rightarrow Y \), \( \Psi : X \rightarrow Y \) and constants \( D_X, D_Y \) such that for all \( x \in X \), \( y \in Y \)

\[
d(x, \Psi \Phi x) \leq D_X, \quad d(\Psi \Phi y, y) \leq D_Y.
\] (2.2)
Proposition 2.8 \( Y \in \text{comp}_{GH}(X) \), i. e. \( d_{GH}(X, Y) < \infty \) if and only if \( X \) and \( Y \) are metrically semilinear equivalent.

We refer to [8] for the proof. \( \square \)

At this general level there are still some important further classes of maps in the category of proper metric spaces.

We call a map \( \Phi : X \to Y \) coarse if it is
1. metrically proper, i. e. for each bounded set \( B \subseteq Y \) the inverse image \( \Phi^{-1}(B) \) is bounded in \( X \), and
2. uniformly expansive, i. e. for \( R > 0 \) there is \( S > 0 \) s. t. \( d(x_1, x_2) \leq R \) implies \( d(\Phi x_1, \Phi x_2) \leq S \).

A coarse map is called rough if it is additionally uniformly metrically proper. \( X \) and \( Y \) are called coarsely or roughly equivalent if there exist coarse or rough maps \( \Phi : X \to Y \), \( \Psi : Y \to X \), respectively, satisfying (2.2). A metrically proper map \( \Phi : X \to Y \) is called Lipschitz if there holds \( d(\Phi(x_1), \Phi(x_2)) \leq C \Phi \cdot d(x_1, x_2) \). Lipschitz maps are continuous. \( X \) and \( Y \) are called coarsely Lipschitz equivalent if there are Lipschitz maps \( \Phi : X \to Y \), \( \Psi : Y \to X \) satisfying (2.2). If additionally \( \Psi \Phi \) and \( \Phi \Psi \) are homotopic to \( \text{id}_X \), \( \text{id}_Y \) by means of a Lipschitz homotopy, respectively, then \( X \) and \( Y \) are called coarsely Lipschitz homotopy equivalent.

The following is immediately clear from the definitions.

Proposition 2.9 A metrically semilinear map is rough and a rough map is coarse. Hence there are inclusions

metrically semilinear equivalence class of \( X \) (\( \equiv \text{comp}_{GH}(X) \)) \( \subseteq \) rough equivalence class of \( X \)

and

course Lipschitz homotopy equivalence class of \( X \) \( \subseteq \) coarse Lipschitz equivalence class of \( X \).

\( \square \)

For later applications to open manifolds \((M^n, g)\) we will sharpen the Lipschitz notions by requiring not only (2.2) but additionally controlling the Lipschitz constants.

From now on we define a Lipschitz map as defined above additionally to be uniformly metrically proper.

Define for a Lipschitz map \( \Phi : X \to Y \)

\[
dil \Phi := \sup_{\substack{x_1, x_2 \in X \\ x_1 \neq x_2}} \frac{d(\Phi x_1, \Phi x_2)}{d(x_1, x_2)}.
\]

Set

\[
d_L(X, Y) := \inf \{ \max \{0, \log \dil \Phi \} + \max \{0, \log \dil \Psi \} + \sup_{x \in X} d(\Psi \Phi x, x) + \sup_{y \in Y} d(\Phi \Psi y, y) \mid \Phi : X \to Y, \Psi : Y \to X \text{ Lipschitz maps} \},
\]
if \{\ldots\} \neq \emptyset and \inf\{\ldots\} < \infty and set \(d_L(X,Y) = \infty\) in the other case. Then \(d_L \geq 0\), symmetric and \(d_L(X,Y) = 0\) if \(X\) and \(Y\) are isometric. Set \(\mathcal{M}_L = \mathcal{M}/\sim\), where \(X \sim Y\) if \(d_L(X,Y) = 0\).

Let \(\delta > 0\) and define
\[
V_\delta = \{(X,Y) \in \mathcal{M}_L^2 | d_L(X,Y) < \delta\}.
\]

The proofs of the following assertions are already more technical and lengthy. Hence we must refer to [8].

**Proposition 2.10** \(\mathcal{L} = \{V_\delta\}_{\delta > 0}\) is a basis for a metrizable uniform structure \(\mathcal{U}_L(\mathcal{M}_L)\)

Denote by \(\mathcal{M}_L(nc)\) the (class of) noncompact proper metric spaces.

**Proposition 2.11** \(\mathcal{M}_L(nc)\) is complete with respect to \(\mathcal{U}_L(\mathcal{M}_L)\).

**Proposition 2.12** \(\mathcal{M}_L\) and \(\overline{\mathcal{M}}_L(nc) = \mathcal{M}_L(nc) \subset \mathcal{M}_L\) are locally arcwise connected. Hence components coincide with arc components, components are open and \(\mathcal{M}_L\) and \(\overline{\mathcal{M}}_L(nc) = \mathcal{M}_L(nc)\) have topological sum representations
\[
\mathcal{M}_L = \text{comp}_L(\text{point}) + \sum_{i \in I} \text{comp}_L X_i \\
\mathcal{M}_L(nc) = \sum_{i \in I} \text{comp}_L X_i \quad \text{and} \\
\text{comp}_L(X) = \{Y \in \mathcal{M}_L | d_L(X,Y) < \infty\}.
\]

In particular all compact spaces lie in the component of the 1–point–space.

A sharpening of this uniform structure is given if we restrict the maps to Lipschitz homeomorphisms.

Define
\[
d_{L,\text{top}}(X,Y) = \inf\{\max\{0, \log \text{dil } \Phi\} + \max\{0, \log \text{dil } \Phi^{-1}\} \mid \Phi : X \to Y \text{ bi–Lipschitz homeomorphism}\}
\]

if there exists such a \(\Phi\) and define \(d_{L,\text{top}}(X,Y) = \infty\) if they are not bi–Lipschitz homeomorphic. Then \(d_{L,\text{top}} \geq 0\), symmetric and \(d_{L,\text{top}}(X,Y) = 0\) if \(X\) and \(Y\) are isometric. Set \(\mathcal{M}_{L,\text{top}} = \mathcal{M}/\sim\), \(X \sim Y\) if \(d_{L,\text{top}}(X,Y) = 0\), and set
\[
V_\delta = \{(X,Y) \in \mathcal{M}_{L,\text{top}}^2 \mid d_{L,\text{top}}(X,Y) < \delta\}.
\]

**Proposition 2.13** \(\mathcal{L} = \{V_\delta\}_{\delta > 0}\) is a basis for a metrizable uniform structure \(\mathcal{U}_{L,\text{top}}(\mathcal{M}_{L,\text{top}})\).
Proposition 2.14

a) $\overline{M}_{L,\text{top}}^{\mu_0} = M_{L,\text{top}}$.

b) $M_{L,\text{top}}$ is locally arcwise connected. Hence components coincide with arc components and components are open.

c) $M_{L,\text{top}}$ has a decomposition as a topological sum,

$$M_{L,\text{top}} = \sum_{i \in I} \text{comp} \,(X_i).$$

d) $\text{comp} \,(X) = \text{comp}_{L,\text{top}} \,(X) = \{ Y \in M_{L,\text{top}}(X,Y) < \infty \}.$

Remark. We see that 2.14 a) is in $U_{L,\text{top}}$ valid without restriction to noncompact spaces as we due in the $U_{L}$–case.

Finally we define still three further uniform structures which measure or express the homotopy neighborhoods and, secondly, admit only compact deviations of the spaces inside one component.

Define

$$d_{L,h}(X,Y) := \inf \left\{ \max \{0, \log \text{dil} \Phi \} + \max \{0, \log \text{dil} \Psi \} + \sup_{X} d(\Psi \Phi x, x) + \sup_{Y} d(\Phi \Psi y, y) \mid \Phi : X \longrightarrow Y, \Psi : Y \longrightarrow X \text{ are (uniformly proper) Lipschitz homotopy equivalences, inverse to each other} \right\}$$

if there exist such a homotopy equivalences and set $d_{L,h}(X,Y) = \infty$ in the other case. Here and in the sequel we require from the homotopies to $id_X$ or $id_Y$, respectively, that they are uniformly proper and Lipschitz.

$d_{L,h} \geq 0$, $d_{L,h}$ is symmetric and $d_{L,h}(X,Y) = 0$ if $X$ and $Y$ are isometric. Define $M_{L,h} = M/ \sim$, $X \sim Y$ if $d_{L,h}(X,Y) = 0$ and set

$$V_\delta = \{(X,Y) \in M^2_{L,h} | d_{L,h}(X,Y) < \delta \}.$$

Proposition 2.15 $\mathcal{L} = \{V_\delta \}_{\delta > 0} \text{ is a basis for a metrizable uniform structure } U_{L,h}M_{L,h}.$

Proposition 2.16

a) $\overline{M}_{L,h}^{d_{L,h}}(nc) = M_{L,h}(nc)$.

b) $M_{L,h}$ is locally arcwise connected. Hence components conincide with arc components and components are open.

c) $M_{L,h}$ has a representation as a topological sum,

$$M_{L,h} = \sum_{i \in I} \text{comp} \,(X_i).$$

d) $\text{comp} \,(X) \equiv \text{comp}_{L,h} \,(X) = \{ Y \in M_{L,h}|d_{L,h}(X,Y) < \infty \}.$
Let $\Phi : X \to Y$, $\Psi : Y \to X$ be Lipschitz maps. We say $\Phi$ and $\Psi$ are stable Lipschitz homotopy equivalences at $\infty$ inverse to each other if there exists a compact set $K^0_X \subset X$ s. t. for any $K^0_X \subset K_X$ there exists $K_Y \subset Y$ s. t. $\Phi_{X \setminus K_X} : X \setminus K_X \to Y \setminus K_Y$ is a Lipschitz h. e. with homotopy inverse $\Psi|_{Y \setminus K_Y}$ and $\Psi$ has the analogous property.

Set

$$d_{L,h,rel}(X,Y,\text{rel}) := \inf \left\{ \max\{0, \log \text{dil } \Phi\} + \max\{0, \log \text{dil } \Psi\} + \sup_X d(\Psi \Phi_x, x) + \sup_Y d(\Phi \Psi_y, y) \right\}$$

if there exist such a $\Phi$, $\Psi$ and set $d_{L,h,rel}(X,Y) = \infty$ is the other case. Then $d_{L,h,rel} \geq 0$, symmetric and $d_{L,h,rel} = 0$ if $X$ and $Y$ are isometric. Set $\mathcal{M}_{L,h,rel} = \mathcal{M}/ \sim$, $X \sim Y$ if $d_{L,h,rel}(X,Y) = 0$ and set

$$V_\delta = \{(X,Y) \in \mathcal{M}^2_{L,h,rel} | d_{L,h,rel}(X,Y) < \delta\}.$$

**Proposition 2.17** $\mathcal{L} = \{V_\delta\}_{\delta > 0}$ is a basis for a metrizable uniform structure $\mathcal{U}_{L,h,rel}$.

\[ \square \]

**Proposition 2.18**

a) $\overline{\mathcal{M}}_{L,h,rel}(\text{nc}) = \mathcal{M}_{L,h,rel}(\text{nc})$.

b) $\mathcal{M}_{L,h,rel}$ is locally arcwise connected. In particular components coincide with arc components, components are open and $\mathcal{M}_{L,h,rel}$ has a representation as topological sum,

$$\mathcal{M}_{L,h,rel} = \sum_{i \in I} \text{comp } (X_i),$$

where

$$\text{comp } (X) \equiv \text{comp}_{L,h,rel} (X) = \{Y \in \mathcal{M}_{L,h,rel} | d_{L,h,rel}(X,Y) < \infty\}.$$  

\[ \square \]

The last uniform structure $\mathcal{U}_{L,top,rel}$ is defined by $d_{L,top,rel}(X,Y)$, where we require that $\Phi : X \to Y$, $\Psi : Y \to X$ are outside compact sets bi–Lipschitz homeomorphisms, inverse to each other. We obtain $\mathcal{M}_{L,top,rel}$. There holds $\overline{\mathcal{M}}_{L,top,rel} = \mathcal{M}_{M,top,rel}$. The other assumptions of 2.16 hold correspondingly.

We finish the section with a scheme which makes clear the achievements.

One coarse equivalence class

$\searrow$ splits into $\nearrow$

many GH–components many L–components,
one \(L\)-component

\[\leftarrow\text{splits into}\rightarrow\]

\(L,\text{top,rel–components}\) \(\quad\)
\(L,\text{h,rel–components}\)

\[\leftarrow\quad\rightarrow\]

\(L,\text{top–components}\) \(\quad\)
\(L,\text{h–components}\).

It is now a natural observation that the classification of noncompact proper metric spaces splits into two main tasks

1. ”counting” the components at any horizontal level,
2. ”counting” the elements inside each component.

A really complete solution of this two problems, i. e. a complete characterization by computable and handable invariants, is now a day hopeless. It is a similar platonic goal as the ”classification of all topological spaces”. Nevertheless stands the task to define series of invariants which at least permit to decide (in good cases) nonequivalence. This will be the topic of section 5.

Finally we remark that \(GH\)-components \((d_{GH}(X,Y) < \infty)\) and \(L\)-components \((d_L(x,Y))\) are very different. Roughly spoken, \(d_{GH}\) is in the small unsharp and in the large relatively sharp, \(d_L\) quite inverse. We refer for many geometric examples to [8].

3 Some materials from nonlinear global analysis on open manifolds

Let \((M^n, g)\) be a Riemannian manifold. We consider the conditions (I) and (B\(_k\)),

(I) \(r_{inj}(M^n, g) = \inf_{x \in M} r_{inj}(x) > 0,\)

(B\(_k\)) \(|\nabla^i R| \leq C_i, \quad 0 \leq i \leq k,\)

where \(r_{inj}\) denotes the injectivity radius, \(\nabla = \nabla^g\) the Levi-Civita connection, \(R = R^g\) the curvature and \(|\cdot|\) the pointwise norm. \((M^n, g)\) has bounded geometry of order \(k\) if it satisfies the conditions (I) and (B\(_k\)). Every compact manifold \((M^n, g)\) or homogeneous Riemannian space or Riemannian covering \((\tilde{M}, \tilde{g})\) of a compact manifold \((M^n, g)\) satisfies (I) and (B\(_\infty\)). More general, given \(M^n\) open and \(0 \leq k \leq \infty\), there exists a complete metric of bounded geometry of order \(k\) (cf. [19]), i.e. the existence of such a metric does not restrict the underlying topological type. (I) implies completeness. Let \((E, h) \rightarrow (M^n, g)\) be a Riemannian vector bundle and \(\nabla = \nabla^h\) a metric connection with respect to \(h\). Quite analogously we consider the condition

(B\(_k\)(E, \(\nabla\))) \(|\nabla^i R^E| \leq C_i, \quad 0 \leq i \leq k,\)

where \(R^E\) denotes the curvature of \((E, \nabla)\).

Lemma 3.1 If \((M^n, g)\) satisfies (B\(_k\)) and \(U\) is an atlas of normal coordinate charts of radius \(\leq r_0\) then there exist constants \(C_\alpha, C'_\beta\) such that

\[|D^\alpha g_{ij}| \leq C_\alpha, \quad |\alpha| \leq k,\quad (3.1)\]

\[|D^\beta \Gamma^m_{ij}| \leq C'_\beta, \quad |\beta| \leq k - 1,\quad (3.2)\]
where \( C_\alpha, C_\beta \) are independent of the base points of the normal charts and depend only on \( r_0 \) and on curvature bounds including bounds for the derivations.

We refer to [11] for the rather long and technical proof which uses iterated inhomogeneous Jacobi equations.

This lemma carries over to the case of Riemannian vector bundles. A normal chart \( U \) in \( M \) of radius \( \leq r_0 \), an orthonormal frame \( e_1, \ldots, e_N \) over the base point \( p \in U \subset M \) and its radial parallel translation define a local orthonormal frame field \( e_\alpha \), a so called synchronous frame and connection coefficients \( \Gamma^\beta_{\alpha i} \) by

\[
\nabla_{\frac{\partial}{\partial x^i}} e_\alpha = \Gamma^\beta_{\alpha i} e_\beta.
\]

**Lemma 3.2** Assume \((B_k(M^n, g)), (B_k(E, \nabla))\), \( k \geq 1 \), and \( \Gamma^\beta_{\alpha i} \) as above. Then

\[
|D^\gamma \Gamma^\beta_{\alpha i}| \leq C_{\gamma}, \quad |\gamma| \leq k - 1, \quad \alpha, \beta = 1, \ldots, N, \quad i = 1, \ldots, n,
\]

where the \( C_{\gamma} \) are constants depending on curvature bounds, \( r_0 \), and are independent of \( U \).

We refer to [11] for the proof.

We recall for what follows some simple facts concerning Sobolev spaces on open manifolds.

Let \((E, h, \nabla^h) \rightarrow (M^n, g)\) be a Riemannian vector bundle. Then the Levi-Civita connection \( \nabla^g \) and \( \nabla^h \) define metric connections \( \nabla \) in all tensor bundles \( T^u v \otimes E \). Denote by \( C^\infty(T^u v \otimes E) \) all smooth sections, \( C^\infty_c(T^u v \otimes E) \) those with compact support. In the sequel we write \( E \) instead of \( T^u v \otimes E \), keeping in mind that \( E \) can be an arbitrary vector bundle. Now we define for \( p \in \mathbb{R}, \quad 1 \leq p < \infty \) and \( r \) a nonnegative integer

\[
|\varphi|_{p,r} := \left( \int \sum_{i=0}^{r} |\nabla^i \varphi|^p_x dvol_x(g) \right)^{1/p},
\]

\[
\Omega^p_r(E) = \{ \varphi \in C^\infty(E) \mid |\varphi|_{p,r} < \infty \},
\]

\[
\Omega^{p,r}_c(E) = \text{completion of } \Omega^p_r(E) \text{ with respect to } |\cdot|_{p,r},
\]

\[
\bar{\Omega}^{p,r}(E) = \text{completion of } C^\infty_c(E) \text{ with respect to } |\cdot|_{p,r} \text{ and}
\]

\[
\Omega^{p,r}(E) = \{ \varphi \mid \varphi \text{ measurable distributional section with } |\varphi|_{p,r} < \infty \}.
\]

Furthermore, we define

\[
b^m|\varphi| := \sum_{i=0}^{m} \sup_x |\nabla^i \varphi|_x,
\]

\[
b^m \Omega(E) = \{ \varphi \mid \varphi \text{ } C^m \text{ - section and } b^m|\varphi| < \infty \} \text{ and}
\]

\[
b^m \bar{\Omega}^{p,r}(E) = \text{completion of } C^\infty_c(E) \text{ with respect to } b^m|\cdot|.
\]
$b,m\Omega(E)$ equals the completion of

$$
\overset{b,m}{\Omega}(E) = \{ \varphi \in C^\infty(E) \mid b,m|\varphi| < \infty \}
$$

with respect to $b,m|\cdot|$.

**Proposition 3.3** The spaces $\overset{\circ}{\Omega}^{p,r}(E)$, $\bar{\Omega}^{p,r}(E)$, $\Omega^{p,r}(E)$, $\overset{b,m}{\Omega}(E)$, $\overset{b,m}{\Omega}(E)$ are Banach spaces and there are inclusions

$$
\overset{\circ}{\Omega}^{p,r}(E) \subseteq \bar{\Omega}^{p,r}(E) \subseteq \Omega^{p,r}(E),
$$

$$
\overset{b,m}{\Omega}(E) \subseteq \overset{b,m}{\Omega}(E).
$$

If $p = 2$ then $\overset{\circ}{\Omega}^{2,r}(E)$, $\bar{\Omega}^{2,r}(E)$, $\Omega^{2,r}(E)$ are Hilbert spaces. □

$\overset{\circ}{\Omega}^{p,r}(E)$, $\bar{\Omega}^{p,r}(E)$, $\Omega^{p,r}(E)$ are different in general.

**Proposition 3.4** If $(M^n, g)$ satisfies (I) and $(B_k)$ then

$$
\overset{\circ}{\Omega}^{p,r}(E) = \bar{\Omega}^{p,r}(E) = \Omega^{p,r}(E), \quad 0 \leq r \leq k + 2.
$$

We refer to [12] for the proof. □

**Theorem 3.5** Let $(E, h, \nabla^E) \rightarrow (M^n, g)$ be a Riemannian vector bundle satisfying (I), $(B_k(M^n, g))$, $(B_k(E, \nabla))$, $k \geq 1$.

a) Assume $k \geq r$, $r - \frac{n}{p} \geq s - \frac{n}{q}$, $r \geq s$, $q \geq p$. Then

$$
\Omega^{p,r}(E) \hookrightarrow \Omega^{q,s}(E)
$$

continuously.

b) If $r - \frac{n}{p} > s$, then

$$
\Omega^{p,r}(E) \hookrightarrow b,s\Omega(E)
$$

continuously.
A key role for many calculations and estimates in nonlinear global analysis plays the module structure theorem which asserts under which conditions the tensor product of two Sobolev sections is again a Sobolev section. We do not use this theorem here explicitely and refer to [13].

We consider in section 4 spaces of metrics and give now a very small review of that. Let \( M^n \) be an open smooth manifold, \( \mathcal{M} = \mathcal{M}(M) \) the space of all complete Riemannian metrics. Let \( g \in \mathcal{M} \). We define
\[
^bU(g) = \{ g' \in \mathcal{M} | g - g' \mid_g := \sup_{x \in M} |g - g'|_{g,x} < \infty, ^b|g - g'|_g < \infty \}.
\]
It is easy to see that \(^bU(g)\) coincides with the quasi isometry class of \( g \), i.e. \( g' \in ^bU(g) \) if and only if there exist \( c, c' > 0 \) such that
\[
c \cdot g' \leq g \leq c' \cdot g'.
\]

Denote for \( g, g' \in \mathcal{M} \) by \( \nabla = \nabla^g \), \( \nabla' = \nabla^{g'} \) the Levi-Civita connections. Set for \( m \geq 1, \delta > 0 \)
\[
V_{\delta} = \{ (g, g') \in \mathcal{M}^2 | |g - g'|_g < \delta, ^b|g - g'|_{g'} < \delta \text{ and }
^b,m|g - g'|_g := ^b|g - g'|_g + \sum_{j=0}^{m-1} ^b|\nabla^j(\nabla - \nabla')|_g < \delta \}.
\]

**Proposition 3.6** The set \( \mathcal{B} = \{ V_{\delta} \}_{\delta > 0} \) is a basis \( \mathcal{B} \) for a metrizable uniform structure on \( \mathcal{M} \).

Denote by \(^{b,m}\mathcal{M}\) the corresponding completed uniform space.

**Proposition 3.7** The space \(^{b,m}\mathcal{M}\) is locally contractible.

**Corollary 3.8** In \(^{b,m}\mathcal{M}\) components and arc components coincide.

Set
\[
^{b,m}U(g) = \{ g' \in ^{b,m}\mathcal{M} | ^b|g - g'|_{g'} < \infty, ^{b,m}|g - g'|_g < \infty \}.
\]

**Proposition 3.9** Denote by \( \text{comp}(g) \) the component of \( g \in ^{b,m}\mathcal{M} \). Then
\[
\text{comp}(g) = ^{b,m}U(g).
\]

**Theorem 3.10** The space \(^{b,m}\mathcal{M}\) has a representation as a topological sum
\[
^{b,m}\mathcal{M} = \sum_{i \in I} ^{b,m}U(g_i).
\]
Theorem 3.11 Each component of $b,m \mathcal{M}$ is a Banach manifold.

Denote for given $M$

$$\mathcal{M}(I, B_k) = \{ g \in \mathcal{M} | g \text{ satisfies } (I) \text{ and } (B_k) \}.$$ 

Remark. $(I)$ always implies completeness. \hfill \qed

Metrics of bounded geometry wear a natural inner Sobolev topology. Let $k \geq r < \frac{n}{p} + 1$, $\delta > 0$ and set

$$V_\delta = \{(g, g') \in \mathcal{M}(I, B_k)^2 | b|g - g'|_g < \delta, b|g - g'|_{g'} < \delta \text{ and }$$

$$|g - g'|_{q, p, r} := \left( \int |g - g'|_{g, x} + \sum_{i=0}^{r-1} |\nabla^i (\nabla - \nabla')|_{g, x}^p \text{dvol}_x(g) \right)^{\frac{1}{p}} < \delta \}.$$ 

Proposition 3.12 The set $\{V_\delta\}_{\delta > 0}$ is a basis for a metrizable uniform structure on $\mathcal{M}(I, B_k)$. Denote by $\mathcal{M}^{p,r}$ the corresponding completed uniform space.

Proposition 3.13 The space $\mathcal{M}^{p,r}(I, B_k)$ is locally contractible.

Corollary 3.14 In $\mathcal{M}^{p,r}(I, B_k)$ components and arc components coincide.

Set for $g \in \mathcal{M}^{p,r}(I, B_k)$

$$U^{p,r}(g) = \{ g' \in \mathcal{M}^{p,r}(I, B_k) | b|g - g'|_g < \infty, b|g - g'|_{g'} < \infty, b|g - g'|_{g, p, r} < \infty \}.$$

Proposition 3.15 Denote by $\text{comp}(g)$ the component of $g \in \mathcal{M}^{p,r}(I, B_k)$. Then

$$\text{comp}(g) = U^{p,r}(g).$$

Theorem 3.16 Let $M^n$ be open, $k \geq r > \frac{n}{p} + 1$. Then $\mathcal{M}^{p,r}(I, B_k)$ has a representation as a topological sum

$$\mathcal{M}^{p,r}(I, B_k) = \sum_{i \in I} U^{p,r}(g_i).$$

We refer to [14] for all proofs.

Finally we give one hint to the manifolds of maps theory. Let $(M^n, g)$, $(N^n', h)$ be open, satisfying $(I)$ and $(B_k)$ and let $f \in C^\infty(M, N)$. Then the differential $df = f_* = Tf$ is a section of $T^*M \otimes f^*TN$. $f^*TN$ is endowed with the induced connection $f^*\nabla^h$. The connections $\nabla^g$ and $f^*\nabla^h$ induce connections $\nabla$ in all tensor bundles $T^*_x(M) \otimes f^*T^{\ast}_{v}(N)$. Therefore, $\nabla^mdf$ is well defined. Assume $m \leq k$. We denote by $C^{\infty, m}(M, N)$ the set of all $f \in C^\infty(M, N)$ satisfying

$$b,m|df| = \sum_{i=0}^{m-1} \sup_{x \in M} |\nabla^i df|_x < \infty.$$ 

It is now possible to define for $C^{\infty, m}(M, N)$ uniform structures to obtain manifolds of maps $b,m\Omega(M, N)$, $\Omega^{p,r}(M, N)$, manifolds of diffeomorphisms $b,mD(M, N)$, $D^{p,r}(M, N)$ and groups of diffeomorphisms $b,mD(M)$, $D^{p,r}(M)$.

But this approach is extraordinarily complicated and extensive. We refer to [15].

Remark. For closed manifolds all these things are very simple. \hfill \qed
4 Uniform structures of open manifolds

Any complete Riemannian manifold \((M^n, g)\) defines a proper metric space and hence an element of \(\mathcal{M}, \mathcal{M}_{GH}, \mathcal{M}_L, \mathcal{M}_{L,top,rel}, \mathcal{M}_{L,rel}, \mathcal{M}_{L,h}\). Denote by \(\mathcal{M}^n(mf)\) the subset of (classes of) complete Riemannian \(n\)-manifolds \((M^n, g)\). The restriction of an uniform structure to a subset yields an uniform structure and we obtain uniform spaces \((\mathcal{M}_{GH}^n(mf), \mathcal{U}_{GH}|_{\mathcal{M}_{GH}^n(mf)})\), \((\mathcal{M}_{L}^n(mf), \mathcal{U}_L|_{\mathcal{M}_{L}^n(mf)})\) etc.. These uniform structures do not take into account the smooth and Riemannian structure but only the (distance) metrical structure. Metrically semilinear and Lipschitz maps which enter into the definition of \(d_{GH}, d_L\) etc. are far from being smooth. On the other hand, we defined in [14] and in the last section for one fixed manifold \(M^n\) several uniform structures of Riemannian metrics. Roughly spoken, the space \(\mathcal{M}(M)\) of complete Riemannian metrics \(g\) on \(M\) splits into a topological sum \(\mathcal{M}(M) = \sum_{i \in I} \text{comp} (g_i)\) depending on the norm in question. Then the fundamental question arises how are \(\text{comp} (M, g_i)\) and \(\text{comp}_{GH} (M, g_i)\), \(\text{comp}_L (M, g_i)\) etc. related? We will give very shortly some partial answers in this section. Moreover, we will generalize the (analytically defined) uniform structures of metrics for one fixed manifold to uniform structures of Riemannian manifolds. Still other questions concern the completions of \(\mathcal{M}^n(mf)\) with respect to the considered uniform structures and the completions of certain subspaces of metrics, e. g. Ricci curvature \(\leq 0\). But these more differential geometric questions are outside the space of this paper and will be studied in [16]. Looking at our general approach, the first main interesting questions are the relations between the components defined until now.

**Proposition 4.1** Let \((M^n, g) \in \mathcal{M}^n(mf)\), \(g' \in \text{comp}(g)\subset \text{comp}(\mathcal{M})\), \(m \geq 0\). Then there holds

- **a)** \((M,g') \in \text{comp}_{L,\text{top}}(M,g)\),
- **b)** \((M,g') \in \text{comp}_{L}(M,g)\)

We refer to [8] for the proof. \(\Box\)

**Remark.** We cannot prove this for \(d_{GH}\). \(d_{GH}\) is locally very rough but measures the metric relations in the large relatively exact. But this property does not immediately follow from \(g' \in \text{comp}(g)\). \(\Box\)

**Corollary 4.2** The assertions a) and b) hold if \(g' \in \text{comp}_{p,r}(g) \subset \mathcal{M}_{p,r}(I,B_k)_k\), \(k \geq r > \frac{n}{p} + 1\). \(\Box\)

To admit the variation of \(M\) in \((M^n, g)\) too, we define still another uniform structure. First we admit arbitrary complete metrics, i. e. we do not restrict to metrics of bounded geometry. Consider complete manifolds \((M^n, g)(M^n, g')\) and \(C^{\infty,m}(M, M')\). A diffeomorphism \(f : M \rightarrow M'\) will be called \(m\)–bibounded if \(f \in C^{\infty,m}(M, M')\) and \(f^{-1} \in C^{\infty,m}(M', M)\). Sufficient for this is 1. \(f\) is a diffeomorphism, 2. \(f \in C^{\infty,m}(M, M')\), 3. \(\inf_x |\lambda|_{\text{min}}(df)_x > 0\).

Let \(\delta > 0\) and set

\[
V_{\delta} = \{(M_1^n, g_1), (M_2^n, g_2) \in \mathcal{M}^n(mf)^2 : \text{There exists a diffeomorphism} \ f : M_1 \rightarrow M_2, \ f (m+1) \text{–bibounded} \ (1 + \delta + \delta \sqrt{2n(n-1)})^{-1} \cdot g_1 \leq f^* g_2 \leq (1 + \delta + \delta \sqrt{2n(n-1)}) \cdot g_1 \}
\]
Proposition 4.3 \( \mathcal{L} = \{ V_\delta \}_{\delta > 0} \) is a basis for a uniform structure \( b,m \mathcal{U}_{diff}(\mathcal{M}^n(mf)) \)

We refer to [8] for the long and technical proof. Denote \( \mathcal{M}^n(mf) \) endowed with the \( b,m \mathcal{U}_{diff} \)-topology by \( b,m \mathcal{M}^n(mf) \).

Proposition 4.4 \( b,m \mathcal{M}^n(mf) \) is locally arcwise connected.

Corollary 4.5 In \( b,m \mathcal{M}^n(mf) \) components coincide with arc components.

Theorem 4.6 a) \( b,m \mathcal{M}^n(mf) \) has a representation as topological sum,
\[
b,m \mathcal{M}^n(mf) = \sum_i b,m \text{comp}_{diff}(M_i, g_i).
\]

b)
\[
b,m \text{comp}_{diff}(M, g) = \{(M', g') \in \mathcal{M}^n(mf) \mid \text{There exists a diffeomorphism } f : M \to M' \in C^{\infty, m+1}(M, M') \text{ s. t. } \quad b,m |f^* g' - g|_g < \infty\}.
\]

We refer to [8] for the proof.

Remark. If \( f : (M_0, g_0) \to (M_1, g_1) \) is a diffeomorphism such that \( c_1 \cdot g_0 \leq f^* g_1 \leq c_2 \cdot g_0 \) then \( \text{dil}(f) \leq c_2 \) and \( \text{dil}((f^{-1}) \leq \frac{1}{c_1} \).

Corollary 4.7 If \( (M_1, g_1) \in b,m \text{comp}_{diff}(M_0, g_0) \) then
\[
d_{L, top}((M_0, g_0), (M_1, g_1)), d_L((M_0, g_0), (M_1, g_1)) < \infty.
\]

Remark. If we assume \( (I), (B_k), k \geq m \), then we can complete the \( (m + 1) \)-bibounded diffeomorphisms of \( C^{\infty, m+1}(M_0, M_1) \) to get \( b,m+1 \text{Diff}(M_0, M_1) \) and 4.3 – 4.7 remain valid with \( C^{m+1} \)-diffeomorphisms (bibounded) between manifolds of bounded geometry.

Now we define the uniform structures for the Riemannian case which are parallel to them defined at the end of section 2.

Consider pairs \( (M^n_1, g_1), (M^n_2, g_2) \in \mathcal{M}^n(mf) \) with the following property.

There exist compact submanifolds \( K^n_1 \subset M^n_1, K^n_2 \subset M^n_2 \) and an isometry \( \Phi : M_1 \setminus K_1 \to M_2 \setminus K_2 \).

For such pairs define
\[
b,d_{L, iso, rel}((M_1, g_1), (M_2, g_2)) := \inf\{ \max\{0, \log^b|df|\} + \max\{0, \log^b|dh|\} \}
+ \sup_{x \in M_1} \text{dist}(x, hf \cdot x) + \sup_{y \in M_2} \text{dist}(y, fh \cdot y) \mid f \in C^{\infty}(M_1, M_2), g \in C^{\infty}(M_2, M_1) \text{ and for some } K_1 \subset K \text{ holds } f|_{M_1 \setminus K_1} \text{ is an isometry and } g|_{f(M_1 \setminus K)} = f^{-1}.\]

15
If \((M_1, g_1), (M_2, g_2)\) satisfy (4.1) then \(\ldots\) \(\neq \emptyset\) and \(b^d_{L,iso,rel}(M_1, M_2) = \inf\{\ldots\} < \infty\). If \((M_1, g_1), (M_2, g_2)\) do not satisfy (4.1) then we define \(b^d_{L,iso,rel}((M_1, g_1), (M_2, g_2)) = \infty\).

Proposition 4.8 \(L = \{V_\delta\}_{\delta > 0}\) is a basis for a metrizable uniform structure \(b^U_{L,iso,rel}\).

\[
V_\delta = \{(M_1, (M_2, g_2)) \in (\mathcal{M}^p_{L,iso,rel}(m)f)^2 \mid b^d_{L,iso,rel}((M_1, g_1), (M_2, g_2)) < \delta\}.
\]

Denote by \(b^\mathcal{M}^n_{L,iso,rel}(m)f\) the corresponding uniform space.

Corollary 4.10 If we restrict to open manifolds with injectivity radius \(\geq r\) then manifolds \((M_1, g_1), (M_2, g_2)\) with \(b^d_{L,iso,rel}\)-distance \(< r\) are automatically (uniformly proper) \(\text{bi-Lipschitz homotopy equivalent}\).

Remark. If \((M_1, g_1)\) satisfies (I) or (I) and \((B_k)\) and \(b^d_{L,iso,rel}(M_1, g_1), (M_2, g_2)\) \(< \infty\) then \((M_2, g_2)\) also satisfies (I) or (I) and \((B_k)\).

Corollary 4.11 If we restrict \(b^U_{L,iso,rel}\) to open manifolds with injectivity radius \(\geq r > 0\) then the manifolds in each arc component of this subspace are \(\text{bi-Lipschitz homotopy equivalent}\).
Theorem 4.12  Any component \( M \) only at most countably many types of such pairs (after fixing \( M \) compact submanifolds and consider \((M, g_1), (M, g_2)\)).

\[ (M, g_2) \in \mathcal{M}(m) \] (4.2)

For this reason we denote the left hand side \{\ldots\} of (4.2) by \( \mathcal{M}(m) \).

Example. Let \((M, g_1) = (\mathbb{R}^n, g_{\text{standard}})\). Then \( \mathcal{M}(m, g_{\text{standard}}) \) is in 1–1–relation to \{\( (M^n, g) \mid M^n \) is a closed manifold, \( g \) is arbitrary but flat in an annulus contained in disc neighborhood of a point\}.

This can be generalized as follows.

Theorem 4.12  Any component \( \mathcal{M}(m, g) \) contains at most countably many diffeomorphism types.

Proof. Fix \((M, g) \in \mathcal{M}(m, g)\), an exhaustion \( K_1 \subset K_2 \subset \ldots \subset K_i = M \), by compact submanifolds and consider \((M', g') \in \mathcal{M}(m, g)\). Then there exist \( K' \subset M' \) and \( K_i \subset M \) such that \( M \setminus K_i \) and \( M' \setminus K' \) are isometric. The diffeomorphism type of \( M' \) is completely determined by diffeomorphism type of the pair \((K_1 \cup K', K_i)\) but there are only at most countably many types of such pairs (after fixing \( M \) and \( K_1 \subset K_2 \subset \ldots \)).

That is, after fixing \((M, g)\), the diffeomorphism classification of the elements in \( \mathcal{M}(m, g) \) seems to be reduced to a "handable" countable discrete problem. This is in fact the case in a sense which is parallel to the classification of compact manifolds. This will be carefully and detailed discussed in [8] – [10]. A key role for this plays the following

Lemma 4.13  Let \( \sigma_e(\Delta_q) \) be the essential spectrum of the Laplace operator acting on \( q \)-forms and assume \((M', g') \in \mathcal{M}(m, g)\). Then \( \sigma_e(\Delta_q)(M, g) = \sigma_e(\Delta_q)(M', g'), \) \( 0 \leq q \leq n \).

A further step in this classification approach will be the definition of characteristic numbers for pairs \((M, M')\) and of bordism which will be the content of section 5.

Instead of requiring isometry at infinity we can focus our attention to homotopy properties and define

\[ b^m d_{L,h}((M_1, g_1), (M_2, g_2)) = \inf \{ \max \{0, \log b|df|\} + \max \{0, \log b|dh|\} \}
+ \sup_{x \in M_1} \text{dist} (x, hfx) + \sup_{y \in M_2} \text{dist} (y, fhx) \]

for \( f \in C^{\infty, m}(M_1, M_2), h \in C^{\infty, m}(M_2, M_1), f \) and \( h \) are inverse to each other uniformly proper homotopy equivalences \}, (4.3)
if \( \{ \ldots \} \neq \emptyset \) and if \( \inf \{ \ldots \} < \infty \). In the other case define \( b.m d_{L,h}((M_1, g_1), (M_2, g_2)) = \infty \). Then \( d_{L,h} \geq 0 \), symmetric and \( = 0 \) if \( (M_1, g_1), (M_2, g_2) \) are isometric. Define \( \mathcal{M}_{L,h}^n(mf) = \mathcal{M}_L^n(mf)/\sim \) where \( \sim \) means \( b.m d_{L,h} \)-distance = 0.

Set
\[
V_\delta = \{((M_1, g_1), (M_2, g_2)) \in (\mathcal{M}_{L,h}^n(mf))^2 \mid b.m d_{L,h}((M_1, g_1), (M_2, g_2)) < \delta \}.
\]

**Proposition 4.14** \( \mathcal{L} = \{V_\delta\}_{\delta>0} \) is a basis for a metrizable uniform structure \( m\mathcal{U}_{L,h} \).

Denote by \( b.m \mathcal{M}_{L,h} \) the corresponding uniform space. Here again we cannot prove that \( b.m \mathcal{M}_{L,h}^n(mf) \) is locally arcwise connected. Nevertheless, \( b.m d_{L,h}((M_1, g_1), (M_2, g_2)) < \infty \) implies \( d_L((M_1, g_1), (M_2, g_2)) < \infty \) and hence \( (M_2, g_2) \in \text{comp}_L (M_1, g_1) \). \( \{(M_2, g_2) \in \mathcal{M}_{L,h}^n(mf) \mid b.m d_{L,h}((M_1, g_1), (M_2, g_2)) < \infty \} \subseteq \text{comp}_L (M_1, g_1) \), and we write \( b.m \text{comp}_{L,h} (M_1, g_1) \) for this set.

**Remark.** \( b.m d_{L,h}((M_1, g_1), (M_2, g_2)) = 0 \) implies \( d_{L,h}((M_1, g_1), (M_2, g_2)) = 0 \). The corresponding implication holds in all preceding cases.

In a quite analogous manner as in section 2, proposition 2.15, and as above, i.e. restricting to maps \( \in C^{\infty,m} \), we can define \( b.m d_{L,h,rel}, b.m \mathcal{M}_{L,h,rel}(mf) \) and \( b.m \text{comp}_{L,h,rel} (M, g) \), where \( b.m \text{comp}_{L,h,rel} (M, g) = \{(M', g') \mid b.m d_{L,h,rel}((M, g), (M', g')) < \infty \} \subseteq \text{comp}_{L,h,rel} (M, g) \).

All uniform structures defined until now for manifolds are based on the Banach \( b.m \) \( \| \cdot \| \)-theory. It is possible to construct an extensive theory of uniform structures of manifolds based on the \( \| \cdot \|_{p,r} \)-Sobolev approach. For spaces of metrics and manifolds of maps this has been done e.g. in [14], [15]. We cannot discuss here the Sobolev approach for reasons of space and refer to [8]. An important philosophical hint shall be given. The \( b.m \) \( \| \cdot \| \)-approach for manifolds is more related to the \( d_L \)-uniform structures (as we pointed out), part of the Sobolev approach for manifolds is more related to \( d_{GH} \)-uniform structures.

We conclude this section with the hint to [8] where most of the very long details are represented.

## 5 Bordism groups for open manifolds

We sketch very shortly our approach to bordism theory for open manifolds. Let \( (M^n, g), (M'^n, g') \) be open, oriented, complete. We say \( (M^n, g) \) is bordant to \( (M'^n, g') \) if there exists an oriented complete manifold \( (B^{n+1}, g_B) \) with boundary \( \partial B \) such that the following holds.

1) \( (\partial B, g_B|_{\partial B}) = (M, g) \cup (-M', g') \). Here \( = \) stands for isometry.

2) There exists a uniform Riemannian collar \( \Phi : \partial B \times [0, \delta[ \xrightarrow{\cong} \mathcal{U}_\delta(\partial B) \subset B \), \( \Phi^*(g_B|_{\mathcal{U}_\delta(\partial B)}) = g_B + dt^2 \).

3) There exists \( R > 0 \) such that \( B \subseteq \mathcal{U}_R (M) \), \( B \subseteq \mathcal{U}_R (M') \).

**Remark.** Condition 3) looks like \( d_H^B(M, M') \leq R \), \( d_{GH}(M, M') \leq R \). But this is not necessary the case since 1) and 2) do not imply that \( \partial B = M \cup M' \) is isometrically embedded as metric
length space into the metric length space $B$. $\partial B$ is isometrically embedded as Riemannian manifold but its inner length metric will not be the induced length metric from $B$, even not if $\partial B$ is totally geodesic as we assume by 2).

We denote $(M, g) \sim_b (M', g')$. $B^{n+1}$ is called a bordism.

**Lemma 5.1** $ \sim_b $ is an equivalence relation.

Denote the equivalence = bordism class of $(M, g)$ by $[M, g]$.

**Lemma 5.2** $[M \cup M', g \cup g'] = [M \# M', g \# g']$.

**Remark.** $(M \# M', g \# g')$ is metrically not uniquely defined but its bordism class is.

**Lemma 5.3** Set $[M, g] + [M', g'] = [M \cup M', g \cup g'] = [M \# M', g \# g']$. Then $+$ is well defined and the set of all $[M^n, g]$ becomes an abelian semigroup.

Denote by $\Omega^{nc}_n$ the corresponding Grothendieck group which is the bordism group of all oriented open complete Riemannian manifolds. Here 0 is generated by the diagonal $\Delta$ and $-[[M, g], [M', g']] = [[M', g'], [M, g]]$.

There is no reasonable approach for a calculation of $\Omega^{nc}_n$ known to us. $\Omega^{nc}_n$ is much too large.

The situation rapidly changes if we consider several refinements of the notion of bordism, combining this with a component in $M^n(mf)$ and having additional conditions in mind, e.g. geometric conditions as nonexpanding ends or spectral conditions. Moreover, we would be interested to have a geometric realization of 0 and $-[M, g]$.

First we consider bordism with compact support. Here we require as above 1), 2) and additionally

3) (cs). There exists a compact submanifold $C^{n+1} \subset B^{n+1}$ such that $B \setminus \text{int} C$ is a product bordism, i.e. $(B \setminus \text{int} C, gB|_{B \setminus \text{int} C}) = ((M \setminus \text{int} C) \times [0, 1], g|_{M \setminus \text{int} C} + dt^2)$. 3) (cs) implies 3. (after a compact change of the metric).

Write $\sim_{b,cs}$ for the corresponding bordism. The corresponding bordism group will be denoted by $\Omega^{nc}_n(cs)$. At the first glance, the calculation of $\Omega^{nc}_n(cs)$ or at last the characterization of the bordism classes seems to be very difficult. But this is not the case as we indicate now.

We connect $\Omega^{nc}_n(cs)$ with the components of $b\text{comp}_{L,iso,rel}(\cdot) \subset bM^n_{L,iso,rel}(mf)$.

**Remark.** If $(M_1, g_1), (M_2, g_2) \in b\text{comp}_{L,iso,rel}(M, g)$ then in general $(M_1, g_1) \# (M_2, g_2) \not\in b\text{comp}_{L,iso,rel}(M, g)$. 

Consider $b\text{comp}_{L,iso,rel}(M, g), [[M', g']_{cs}|(M', g') \in b\text{comp}_{L,iso,rel}(M, g)]$ and the subgroup $\Omega^{nc}_n(cs, b\text{comp}_{L,iso,rel}(M, g)) \subset \Omega^{nc}_n(cs)$ generated by $[[M', g']_{cs}|(M', g') \in b\text{comp}_{L,iso,rel}(M, g)]$. 

We know $\Omega_{nc}^n(cs)$ completely if we know all $\Omega_{nc}^n(cs, b_{\text{compL,iso,rel}}(M, g))$ and we know $\Omega_{nc}^n(cs, b_{\text{compL,iso,rel}}(M, g))$ completely if we know $\{[M', g']_c ([M', g'] \in b_{\text{compL,iso,rel}}(M, g))$. But the elements of $\{[M', g']_c ([M', g'] \in b_{\text{compL,iso,rel}}(M, g))$ can be completely characterized by characteristic numbers which we define now.

Fix $(M, g) \in b_{\text{compL,iso,rel}}(M, g)$, $M$ oriented. Let $(M_1, g_1) \in b_{\text{compL,iso,rel}}(M, g)$ and $\Phi : M \setminus K \rightarrow M_1 \setminus K_1$ be an orientation preserving isometry. Define Stiefel Whitney numbers of the pair $(M_1, M)$ by

$$w_1 \ldots w_n(M_1, M) := \langle w_1 \ldots w_n, [K_1] \rangle + \langle w_1 \ldots w_n, [K] \rangle.$$

Similarly we define for $(M_1, M)$ and $n = 4k$ Pontrjagin numbers

$$p_1^1 \ldots p_k^k(M_1, M) := \int_{K_1} p_1^1 \ldots p_k^k(M_1) - \int_{K} p_1^1 \ldots p_k^k(M_1)$$

and the signature

$$\sigma(M_1, M) := \sigma(K_1) + \sigma(-K).$$

**Lemma 5.4** $w_1^1 \ldots w_n^r(M_1, M)$, $p_1^1 \ldots p_k^k(M_1, M)$ and $\sigma(M_1, M)$ are well defined and

$$w_1^1 \ldots w_n^r(M_1, M) = \langle w_1^1 \ldots w_n^r(K_1 \cup K), [K_1 \cup K] \rangle,$$

$$p_1^1 \ldots p_k^k(M_1, M) = \langle p_1^1 \ldots p_k^k(K_1 \cup -K), [K_1 \cup -K] \rangle,$$

$$\sigma(M_1, M) = \sigma(K_1 \cup -K).$$

Here $K_1 \cup -K$ means $K_1 \cup \Phi|_{\partial K}$.

We refer to [9] for the very simple proof.

A complete characterization of bordism classes is now given by

**Theorem 5.5** Fix $(M_1, g_1), (M_2, g_2) \in b_{\text{compL,iso,rel}}(M, g)$. Then $(M_1, g_1) \sim_{b, cs} (M_2, g_2)$ if and only if all characteristic numbers of $(M_1, M)$ coincide with the corresponding characteristic numbers of $(M_2, M)$.

We refer to [9] for the proof.

**Corollary 5.6** The characterization of all elements of $\Omega_{nc}^n(cs)$ reduces to "counting" the (generalized) components of $b_{\text{M,L,iso,rel}(\text{mf})}$.

**Remark.** If we restrict to closed oriented $n$–manifolds then $b_{\text{compL,iso,rel}}(S^n)$ contains all closed oriented $n$–manifolds, independent of any choice of the Riemannian metric, and characteristic numbers defined above of $(M^n, S^n)$ coincide with the characteristic numbers of $M^n$. This follows
from the definition above and the fact that they vanish for $S^n$ or by cutting isometric collared small discs from $M^n$, $S^n$ and gluing.

**Examples.**

1) Consider $M' = (P^{2k} \setminus \text{int (small disc)}) \cup \text{metric cylinder } S^{2k-1} \times [0, \infty]$, corresponding metric) and $M = (2k-\text{disc} \cup \text{metric cylinder } S^{2k-1} \times [0, \infty])$, corresponding metric). Then $(M', g') \in \comp_{L, \text{iso,rel}} (M, g)$ but $(M', g')$ is not $\text{cs}$–bordant to $(M, g)$ since $\sigma(M', M) = 1$, $\sigma(M', M') = 0$.

2) For any $(M, g)$ there is a map $\Phi_n : \Omega_n \to \{([M', g'], \text{cs})(M', g') \in \comp_{L, \text{iso,rel}} (M, g)\}$ given by $[N] \to [M \# N, g']$ independent of the metric on $N$.

There are many other types of bordism which are discussed in [9]. We present still a type of bordism where 0 and $-\mathcal{B}_M$ are geometrically realized. For this sake, we restrict to metrics and bordisms of bounded geometry.

Let $(M^n, g)$, $(M'^n, g')$ be open, oriented, satisfying (I) and $(B_k)$. We say $(M^n, g)$ is (I), $(B_k)$–bordant to $(M'^n, g')$ if there exists an oriented manifold $(B^{n+1}, g_B)$ with boundary $\partial B$ such that the following holds:

1) $(\partial B, g_B|_{\partial B}) = (M, g) \cup (M', g')$.

2) There exists $\delta > 0$ such that $\exp : U_0(0, r) \to U_0(\partial B)$ is a $(k + 2)$–bibounded diffeomorphism, i. e. there exists a "uniform collar" of $\partial B$. Here $0_r$ denotes the zero section of the inner normal bundle $\nu = \nu(\partial B)$ of $\partial B$ in $B$.

3) $g_B$ satisfies $(B_k)$ on $B$ and (I) on $B \setminus U_2(\partial B)$.

4) There exists $R > 0$ such that $B \subseteq U_R(M)$ and $B \subseteq U_R(M')$. We write then $(M, g) \sim_{b,bg} (M', g')$.

**Lemma 5.7** Assume $(M, g) \sim_{b,bg} (M', g')$ via $(B, g_B)$. Then there exist $\delta_1 > 0$ and $\tilde{g}_B$ s. t. $\sim_{b,bg} (M, g)$ via $(B, \tilde{g}), \tilde{g}_B|_{\nu_{\delta_1}(\partial B)} \simeq g_0B + dt^2$.

We refer to [9] for the proof.

**Corollary 5.8** Without loss of generality we can always assume that the collar of $\partial B$ is a metric collar.

**Corollary 5.9** $\sim_{b,bg}$ is an equivalence relation.

Denote by $[M, g]_{bg}$ the equivalence $\equiv$ bordism class of $(M, g)$.

**Lemma 5.10** $[M \cup M', g \cup g']_{bg} = [M \# M', g \# g']_{bg}$. Set $[M, g]_{bg} + [M', g']_{bg} := [M \cup M', g \cup g']_{bg}$. Then $+$ is well defined and $\{([M, g]_{bg}(M, g) \text{ open, oriented with } (I)\text{ and } (B_k))\}$ becomes an abelian semigroup.
Lemma 5.11 Let \((M^n, g)\) be an open manifold satisfying \((I)\) and let \(\varepsilon\) be an end of \(M\). Then there exists a geodesic ray \(c\) tending to \(\infty\) in \(\varepsilon\) with a uniformly thick tubular neighborhood. \(\square\)

We define an end \(\varepsilon\) is nonexpanding (\(\varepsilon\) is a n.e. end), if there exists an \(R > 0\) and a ray \(c\) in \(\varepsilon\) so that \(\varepsilon \subseteq U_R(|c|)\), which means that all elements of a neighborhood basis of \(\varepsilon\) are contained in \(U_R(|c|)\).

We now restrict to manifolds with finitely many n.e. ends only. Define \(\text{chc}(r) := (D^n \cup S^{n-1}_r \times [0, \infty[, g_{\text{standard}})\), where \(g_{\text{standard}}|_{S^{n-1}_r \times [a, \infty[} = g_{S^{n-1}_r} + dt^2\) and the standard metrics near \(\partial D^n\) are smoothed out. Then \(\text{chc}(r)\) has one end, nonexpanding, and satisfies \((I)\) and \((B_\infty)\).

Lemma 5.12 \(\text{chc}(r_1) \sim_{b,bg} \bigcup_{\sigma=1}^s \text{chc}(r_\sigma) \sim_{b,bg} \text{chc}(r)\). \(\square\)

Define now
\[-[M, g] := [-M, g],
0 := [\text{chc}(1)]\]
and set \(\Omega^{nc,fe,ne}_n(I, B_k) :=\) all \([M^n, g]_{bg}\) with finitely many ends \((fe)\), all of them nonexpanding n.e..

Theorem 5.13 \((\Omega^{nc,fe,ne}_n(I, B_k), +, -, 0)\) is an abelian group.

We refer to [9] for the proof, which contains throughout some delicate geometric constructions. \(\square\)

Examples of manifolds of type f.e., n.e., \((I)\), \((B_k)\) are given by warped product metrics at infinity with \(C^{k+2}\)–bounded warping function and e.g. by ends which are an infinite connected sum of a finite number of closed Riemannian manifolds.

We finish with these two (very handable) examples \(\Omega^{nc}(cs), \Omega^{nc,fe,ne}_n(I, B_k)\) our short review of bordism theory for open manifolds and refer to [9] for an extensive representation.

6 Invariants of open manifolds

Consider \((M^n, g)\) with \((I)\) and \((B_k)\), usually \(k \geq \frac{n}{2} + 1\). \((M^n, g)\) is a proper metric (length) space and we have sequences of inclusions

\[
\text{coarse type}(M, g) \supset \text{comp}_{GH}(M, g) \quad (6.1)
\]
\[
\text{coarse type}(M, g) \supset \text{comp}_L(M, g) \supset \text{comp}_{L,h}(M, g) \supset \text{comp}_{L,top}(M, g) \quad (6.2)
\]
\[
\text{comp}_L(M, g) \supset^{b,m} \text{comp}_L(M, g) \supset^{b,m} \text{comp}_{diff}(M, g) \quad (6.3)
\]
\[
b^{b,m} \text{comp}_L(M, g) \supset^{b,m} \text{comp}_{L,h}(M, g) \supset^{b,m} \text{comp}_{diff}(M, g) \quad (6.4)
\]
\[
b^{b,m} \text{comp}_{L,h,rel}(M, g) \supset b \text{ comp}_{L,iso,rel}(M, g) \quad (6.5)
\]
and others. The arising task is to define for any sequence of inclusions invariants depending only on the component and becoming sharper and sharper if we move from left to right. We cannot present here all by us and others defined invariants but present a certain choice. Start with the coarse type. Denote by \( C^*(M, g) \) the \( C^* \)-algebra obtained as the closure in \( B \) of \( L^2 M \) of all locally compact, finite propagation operators and by \( HX^*(M, g) \) the coarse cohomology. Then we have from [22], [23]

**Theorem 6.1** \( HX^*(M, g) \) and the \( K \)-theory \( K_\ast(C^*(M, g)) \) are invariants of the coarse type, hence invariants of all components right from the coarse type.

**Remarks.**

1) We tried to describe the coarse type as the component of some uniform structure but there is still some gap in this approach.

2) Recall that a rough map is a coarse map which is uniformly proper. The rough type is defined like the coarse type, replacing only coarse maps by rough maps.

Block and Weinberger defined in [3] an homology \( H^U_{\ast f}(M, g) \) which we here call rough homology (since it is functional under rough maps). We prove in [8] that the rough and coarse type coincide.

**Theorem 6.2** The rough homology \( H^U_{\ast f}(M, g) \) is an invariant of the coarse type.

Define the (singular) uniformly locally finite homology \( H^U_{Uff}(M, g) \) as follows. It is the homology of the complex \( C^U_{Uff}(M, g) \). \( c = \sum a_\sigma \sigma \) is a chain of \( C^U_{Uff} \) if there exists \( K > 0 \) depending on \( c \) so that \( |a_\sigma| \leq K \) and the number of simplices \( \sigma \) lying in a ball of given size is uniformly bounded. The boundary is defined to be the linear extension of the singular boundary. Similarly is the uniformly locally finite cohomology \( H_{Uff}^U(M, g) \) defined (cf. [1]).

**Theorem 6.3** \( H^U_{Uff}(M, g) \) and \( H^U_{Uff}(M, g) \) are invariants of \( \text{comp}_{L,h}(M, g) \)

Consider the bounded de Rham complex of \((M, g)\),

\[
\cdots \to b_{1}^{1} \Omega^{q} \overset{d}{\to} b_{1}^{1} \Omega^{q+1} \to \cdots
\]

Its cohomology is called the bounded cohomology of \( ^b H^\ast(M, g) \).

**Theorem 6.4** \( ^b H^\ast(M, g) \) is an invariant of \( ^{b2}\text{comp}_{L,h}(M, g) \).
Remark. We remember that we required in 5.4 the boundedness of the maps and the homotopies. This is essential.

The $b$-case is the smooth $L_\infty$-case and it is quite natural to consider the $L_p$-case, in particular the $L_2$-case. But here the point is that an arbitrary bounded map $f : (M, g) \to (M', g')$ does not induce an $L_2$-bounded map of analytic $L_2$-cohomology. Hence it is far from being clear whether analytic $L_2$-cohomology is an invariant of $b, k + 1 = \text{comp}_{L, h}(M, g)$. This question can be attacked by simplicial $L_2$-cohomology and $L_2$-Hodge–de Rham theory.

We will discuss this shortly and recall some simple definitions and facts.

Let $K$ be a locally oriented simplicial complex and $\sigma^q \in K$. We denote $I(\sigma^q) = \# \{ \tau^{q+1} \in K | \sigma < \tau^{q+1} \}$. $I_q(K) := \sup I(\sigma^q)$. The complex $K$ is called uniformly locally finite (u. l. f.) in dimension $q$ if $I_q(K) < \infty$. If this holds for all $q$ then we call $K$ (in any dimension) u. l. f.. The latter is equivalent to $I_0(K) < \infty$. We assume in the sequel $K$ u. l. f.. Let for $1 \leq p < \infty$ be $C^{q,p}(K) = \{ c = \sum_{\sigma^q \in K} c_\sigma \cdot |c_\sigma| \in \mathbb{R}, \sum_{\sigma^q} |c_\sigma|^p < \infty \}$ the Banach space of all real $p$-summable $q$-cochains. Then the linear extension of, $d\sigma^q = \sum_{\tau^{q+1} : \sigma^q} [\tau^{q+1} : \sigma^q] \tau^{q+1}$ is a bounded linear operator $d : C^{q,p} \to C^{q+1,p}$, $d(\sum c_\sigma \sigma) = \sum_{\tau^{q+1} : \sigma^q} \left( \sum_{\tau^{q+1} \text{ } : \sigma^q} [\tau : \sigma] \right) \tau^{q+1}$, and we obtain a Banach cochain complex $(C^{q,p}, d)$. Its cohomology $H^{q,p}(K)$ is called simplicial $L_p$-cohomology, $H^{q,p}(K) = Z^{q,p}/B^{q,p} = \ker(d : C^{q,p} \to C^{q+1,p})/\text{im}(d : C^{q-1,p} \to C^{q,p})$. $\overline{H}^{q,p}(K) = Z^{q,p}/B^{q,p}$ is called reduced simplicial $L_p$-cohomology. For $p = 2$, $C^{q,2}(K)$ is a Hilbert space via $\langle c, c' \rangle = \sum_{\sigma^q} c_{\sigma} \cdot c'_{\sigma}$, and we obtain a Hilbert complex $C^{*, 2}(K)$. We refer to [17] and [2] for many simple proofs and interesting geometric examples.

Let $(C^{*, p}, \partial)$, $\partial \sigma^q = \sum_{\tau^{q-1} : \sigma^q} [\tau^{q-1} : \sigma^q] \tau^{q-1}$, $\partial(\sum c_\sigma \sigma) = \sum_{\tau^{q-1} : \sigma^ q} (\sum_{\tau^{q-1} \text{ } : \sigma^q} [\tau : \sigma] c_\sigma) \tau^{q-1}$, be the Banach complex of $p$-summable real chains and $H_{*, p}(K)$ or $\overline{H}_{*, p}(K)$ the corresponding $L_p$–homology or reduced $L_p$–homology, respectively.

Lemma 6.5 If $H^{q,p}(K) \neq \overline{H}^{q,p}(K)$ then there exists an infinite number of independent cohomology classes in $H^{q,p}$ whose image in $\overline{H}^{q,p}$ equals to zero, i. e. dim $\ker H^{q,p} \to \overline{H}^{q,p} = \infty$. The same holds for $L_p$–homology.

Corollary 6.6 If dim $H^{q,p}(K) < \infty$ then $H^{q,p}(K) = \overline{H}^{q,p}(K)$. The same holds for homology.

Remark. $H^{q,p}(K)$ is endowed with a canonical topology, the quotient topology. But if $B^{q,p}$ is not closed then points in $H^{q,p}(K)$ are not closed. In particular, any point $0 \neq \overline{b} + B^{q,p} \in H^{q,p}$, $\overline{b} \in \overline{B}^{q,p} \setminus B^{q,p}$, belongs to the closure $\overline{0} \subset H^{q,p}$.

For $p = 2$ $\partial_{q-1} : C^{q,2} \to C^{q-1,2}$ is the $(\cdot)$–adjoint of $d_{q-1} : C^{q-1,2} \to C^{q,2}$. Then $\Delta_q(K) := d_{q-1} \partial_{q-1} + \partial_q d_q$ is a well defined bounded operator $\Delta_q : C^{q,2}(K) \to C^{q,2}(K)$ and $H^q(K) \cong H^{q,2}(K) := \ker \Delta_q(K)$ is the Hilbert subspace of harmonic $L_2$–cochains = harmonic $L_2$–chains.
Lemma 6.7  a) \( c \in \mathcal{H}^{q,2}(K) \) if and only if \( dc = \partial c = 0 \)

b) There exists an orthogonal decomposition

\[
C^{q,2} = \mathcal{H}^q(K) \oplus dC^{q-1,2} \oplus \partial C^{q+1,2}
\]

c) There are canonical topological isomorphisms

\[
\mathcal{H}^q \cong \overline{H}^{q,2}(K) \cong \overline{H}_{q,2}(K).
\]

Denote by \( \sigma(\Delta_q(K)) \) the spectrum, by \( \sigma_e \) the essential spectrum.

Lemma 6.8  The following conditions are equivalent.

a) \( \text{im} \partial_q \) and \( \text{im} \partial_{q-1} \) are closed.

b) \( \text{im} d_q \) and \( \text{im} d_{q-1} \) are closed.

c) \( \text{im} \Delta_q(K) \) is closed.

d) \( 0 \notin \sigma_e(\Delta_q(K)|_{\ker \Delta_q}) \).

e) \( H^{q,2}(K) = \overline{H}^{q,2}(K) \) and \( H^{q+1,2}(K) = \overline{H}^{q+1,2}(K) \).

f) \( H_{q,2}(K) = \overline{H}_{q,2}(K) \) and \( H_{q-1,2}(K) = \overline{H}_{q-1,2}(K) \).

Example. Let \( K = S^1 \times \mathbb{R} \) with a translation invariant u. l. f. triangulation. Then \( \overline{H}_{1,2}(K) = (0) \), \( \dim H_{1,2}(K) = \infty \), i.e. condition d) is not fulfilled.

For later applications the following simple lemma is quite useful.

Lemma 6.9  Let \( H \) be a Hilbert space and \( \Phi : H \rightarrow H^{q,2}(K) \) be a vector space isomorphism and homeomorphism. Then \( H^{q,2}(K) = \overline{H}^{q,2}(K) \). The same holds as homology version.

We discuss next the behaviour of functional cohomology under maps and subdivision.

We write \( x(y) = (x,y) \) for the value of a \( q \)-cochain \( x \) and a \( q \)-chain \( y \). If \( S \) is a set of oriented \( q \)-simplexes then \( S \) can be considered as a \( q \)-chain \( S \) defined by \( S = \sum_{\sigma \in S} \sigma \). Then \( S \) will be called a geometric \( q \)-chain. Let \( K \) and \( L \) be complexes and \( T : C^{*,p}(K) \rightarrow C^{*,p}(L) \) be a linear map. \( T \) is called vicinal if there exists an \( N \) such that for all \( \sigma \in K \)

\[
\#\{\tau \in L|\langle T\sigma, \tau \rangle \neq 0\} \leq N
\]

and for any \( \tau \in L \)

\[
\#\{\sigma \in K|\langle T\sigma, \tau \rangle \neq 0\} \leq N.
\]

Lemma 6.10  If \( T \) is vicinal and \( |\langle T\sigma, \tau \rangle| \leq M \) for all \( \sigma \in K, \tau \in L \) then \( T \) is bounded.
Let \( v \) be a vertex of \( K \),
\[
st(v) = \{ \sigma \in K | v \text{ is a vertex of } \sigma \},
\]
and for \( \sigma \in K \)
\[
N(\sigma) = \bigcup_{v \in \sigma} st(v),
\]
for \( L \subset K \)
\[
N(L) = \bigcup_{\sigma \in L} N(\sigma)
\]
\[
N^{(m)}(\cdot) := N(N(\ldots(N(\cdot))\ldots)).
\]

We recall some definitions from [2].

A linear map \( T : C^{*\cdot,p}(K_1) \to C^{*\cdot,p}(K_2) \) is local if it is vicinal and there exists a positive integer \( n \) such that whenever there is a simplicial bijection \( \eta : N^n(\sigma) \to N^n(\tau) \) with \( \eta(\sigma) = \tau \) then there exists a simplicial bijection \( \varepsilon : \text{Im}(N^n(\sigma)) \to \text{Im}(N^n(\tau)) \) such that \( T(\eta_\ast(\sigma)) = \varepsilon_\ast(T(\sigma)) \). Here \( \text{Im}(N^n(\sigma)) \) denotes the subcomplex supporting the chain \( T(N^n(\sigma)) \). In other words, a local map is characterized by the following three properties:

1) The image of a simplex \( \sigma \) is a chain whose support has less than \( N \) simplexes, \( N \) independent of \( \sigma \).

2) The number of simplexes whose image contains a simplex \( \tau \) is less than \( N \), \( N \) independent of \( \tau \).

3) The value of the map on a simplex \( \sigma \) depends only on the configuration around \( \sigma \).

These conditions are independent of \( p \) and purely combinatorial in nature.

**Example.** \( d, \partial \) and \( \Delta \) are local operators. \( \square \)

For many applications one can weaken the third condition replacing the existence of the map \( \varepsilon \) by the weaker condition that there exists a constant \( c \) such that
\[
|T(\eta_\ast(\sigma))|_p < c \cdot |T(\sigma)|_p.
\]
Such maps will be called nearly local.

**Lemma 6.11** If \( T \) is nearly local then it is bounded.

Now we want to prove the invariance of functional cohomology under subdivisions of finite degree and apply this for duality on open manifolds. For this we need more general complexes than simplicial ones. An absolute complex is a 3–couple \( K = (K, \prec, \text{dim}) \), \( \text{dim} : K \to \mathbb{Z}_+ \), such that \( \prec \) is a transitive relation, \( \text{dim} \) is monotone w. r. t. \( \prec \) and for every \( x \in K \) there are only finitely many \( y \in K \) with \( y \prec x \). If \( \text{dim} x = n \) then \( x \) is called an \( n \)-cell. \( \varepsilon : K \times K \to \mathbb{Z} \) is called a boundary function or incidence number if \( \varepsilon(x, y) \neq 0 \) implies \( x < y \) and \( \text{dim} y = 1 + \text{dim} x \) and for \( x, y \in K \), \( \text{dim} y = 2 + \text{dim} x \) holds \( \sum_{z \in K} \varepsilon(x, z)\varepsilon(z, y) = 0 \). We write \( K_\varepsilon = (K, \prec, \text{dim}, \varepsilon) \). Then the definition of u. l. f. \( K_\varepsilon \) is quite clear and then the spaces \( C^{\ast\cdot,p}(K_\varepsilon, d), H^{\ast\cdot,p}(K_\varepsilon), T^{\ast\cdot,p}(K_\varepsilon), C_{\ast\cdot,p}(K_\varepsilon), H_{\ast\cdot,p}(K_\varepsilon), T_{\ast\cdot,p}(K_\varepsilon) \) are well defined. Simplicial, cell
and CW–complexes produce their (after orientation) $K_\varepsilon$. It is very easy and natural to extend the notions local and nearly local to this general situation.

Let $K$ be an u. l. f. simplicial complex, $K'$ a subdivision. We say that $K'$ has bounded degree of subdivision if for any $q$ there exists a number $m_q$ s. t. any $\sigma^q \in K$ is subdivided into $\leq m_q q$–simplexes $\sigma'^q \in K'$. Then $K'$ is automatically u. l. f.. For $\sigma^q \in K$ let $B(\sigma^q) = \{ \sigma' \in K' ||\sigma'|| \leq |\sigma^q| \}$. Then $Z(K') = \{ B(\sigma) | \sigma \in K \}$ is a cell decomposition of $K'$ (cf. [21], pp. 528–533 for definitions). $B(\sigma)$ is a finite subcomplex and is called a block. There holds $$H_i(B(\sigma^q), B(\sigma^q); \mathbb{Z}) \cong \begin{cases} \mathbb{Z}, i = q \\ 0, \text{ in any other case.} \end{cases}$$

Choose for any $B(\sigma^q)$ an integer orientation $b$, i. e. a generator of $H_q(B, B; \mathbb{Z})$. Then we obtain oriented blocks $(B, b)$. $b$ has a representation $B = \sum_{i=0}^{\kappa} \gamma_i \sigma_i^q$, where $\sigma_i^q$ are the $q$–simplexes of $B(\sigma^q)$, $\gamma_i = \pm 1$, $\kappa \leq m_q$. Let $(B_1, b_1), \ldots, (B_{q+1}, b_{q+1})$ be the $(q-1)$–blocks of $B$. Then $\partial b$ has a representation $\partial b = \sum_{\nu=1}^{q+1} \varepsilon_{\nu} b_{\nu}$. $\varepsilon_{\nu} = \pm 1$. $[(B, b) : (B_\nu, b_\nu)'] := \varepsilon_n u$ defines incidence numbers and a boundary operator.

Then it is possible by standard procedures to define a cell complex $(Z(K'), [\cdot]')$ such that the following holds

**Lemma 6.12** After appropriate choice of orientation $b$, the map $\sigma^q \rightarrow B(\sigma^q)$ defines an isomorphism $$\zeta : (K, [\cdot]) \rightarrow (Z(K'), [\cdot]').$$

This holds even for arbitrary simplicial complexes and simplicial subdivisions.

In the sequel we abbreviate $Z(K') = (Z(K'), [\cdot]').$

**Corollary 6.13** The map $\zeta : \sigma^q \rightarrow B(\sigma^q)$ induces canonical topological isomorphisms $\zeta_{\#} : C_{*, p}(K) \rightarrow C_{*, p}(Z(K'))$ and $\zeta_* : H_{*, p}(K) \rightarrow H_{*, p}(Z(K'))$. The same holds for $C^*, p$ and $H^*, p$ and for the reduced case.

Let $(B(\sigma^q), b)$ be an elementary $q$–chain of of $C_{*, p}(Z(K'))$. Then we define $$\Theta q(B(\sigma^q), b) := b = \sum_{i=1}^{\kappa} \gamma_i \sigma_i^q \in C_{q, p}(K'), \kappa \leq m_q.$$ Here $\sigma'^q$ are the $q$–simplexes of $B(\sigma^q)$ and $\gamma_i = \pm 1$. We define for $c = \sum_{\sigma^q \in K} c_{B(\sigma^q)}(B(\sigma^q), b) \in C_{q, p}(Z(K'))$ the value $\Theta q c$ by linear extension, $\Theta q c = \sum_{\sigma^q \in K} c_{\sigma^q} \sigma'^q$, where $c_{\sigma^q} = \gamma_{\nu} \cdot c_{B(\sigma^q)}$, $\sigma'^q \in B(\sigma^q)$.

**Lemma 6.14** The map $\Theta = (\Theta q) : C_{*, p}(Z(K')) \rightarrow C_{*, p}(K')$ is an $L_p$–chain map. Any \( \Theta q : C_{q, p}(Z(K')) \rightarrow C_{q, p}(K') \) is a monomorphism.
Lemma 6.15 \( \Theta_q(C_{q,p}(Z(K'))) \) is closed in \( C_{q,p}(K') \).

\[ \square \]

Corollary 6.16 \( \Theta_q : C_{q,p}(Z(K')) \to \text{im}(\Theta_q) \) is a topological isomorphism.

\[ \square \]

Define \( \eta : K' \to K \) as follows. For a vertex \( v' \in K' \) denote by \( tr(e') \) the simplex of smallest dimension which contains \( v' \). Choose for \( v' \) a vertex \( v = \eta(v') \). \( \eta \) is called a vertex translation and defines by extension a simplicial map \( \eta : K' \to K \). Then the following lemma immediately follows from the corresponding lemma in classical homology theory (cf. [21], 49.15, p. 537). We identify \( C_{q,p}(K') \) and \( C_{q,p}(Z(K')) \) by means of \( \zeta \) according to 6.13.

Lemma 6.17 \( (\eta_q) \circ \Theta_q : C_{q,p}(K) \to C_{q,p}(K) \) equals \( id_{C_{q,p}(K)} \).

\[ \square \]

Now we can establish

Theorem 6.18 Let \( 1 \leq p < \infty \) and \( K \) be an u. l. f. simplicial complex and \( K' \) a simplicial subdivision which is of bounded degree of subdivision in any dimension. Then, after identification of \( K \) with \( Z(K') \) by means of \( \zeta \), \( \Theta : C_{*,p}(K) \to C_{*,p}(K') \) induces topological isomorphisms

\[ \Theta_* : H_{*,p}(K) \to H_{*,p}(K') \]

and

\[ \Theta_* : \Phi_{*,p}(K) \to \Phi_{*,p}(K') \].

\[ \square \]

A first approach to homotopy invariance is given by

Theorem 6.19 Let \( K, L \) be u. l. f. simplicial complexes, \( 1 \leq p < \infty \) and \( \varphi_{\#} : C_{*,p}(K) \to C_{*,p}(L) \), \( \psi_{\#} : C_{*,p}(L) \to C_{*,p}(K) \) chain maps satisfying the following conditions.

\[ (C1) \quad \varphi_{\#}, \psi_{\#} \text{ are local.} \]

\[ (C2) \quad \text{There are bounded chain homotopies} \]

\[ \psi_{\#}\varphi_{\#} \sim_1 id_{C_{*,p}(K)}, \quad \varphi_{\#}\psi_{\#} \sim_2 id_{C_{*,p}(L)}. \]

Then \( \varphi_{\#} \) and \( \psi_{\#} \) induce topological isomorphisms

\[ H_{*,p}(K) \xrightarrow{\psi_*} H_{*,p}(L) \]

\[ \Phi_{*,p}(K) \xrightarrow{\psi_*} \Phi_{*,p}(L) \]
Now we apply this to open manifolds \((M^n, g)\) satisfying \((I), (B_k), k > \frac{n}{p} + 1\). Then it is a well known fact that such an \(M\) admits a so called uniform triangulation, i.e. a triangulation \(t: |K| \rightarrow M\) with the following properties.

Let \(\sigma^n\) be a curved \(n\)-simplex in \(M^n\). We define the fullness \(\Theta(\sigma)\) by \(\Theta(\sigma) = \frac{\text{vol} (\sigma)}{\text{diam} (\sigma)^n}\).

\[\text{a)}\] There exists a \(\Theta_0 > 0\) such that for any curved simplex \(\sigma^n\) the fullness satisfies the inequality \(\Theta(\sigma) > \Theta_0\).

\[\text{b)}\] There exist constants \(c_2 > c_1 > 0\) such that for every \(\sigma^n\) we have \(c_2 \leq \text{vol} (\sigma) \leq c_1\).

\[\text{c)}\] There exists a constant \(c > 0\) such that for every vertex \(v \in K\) the barycentric coordinate function \(\varphi_v : M \rightarrow \mathbb{R}\) satisfies the condition \(|\nabla \varphi_v| \leq c\).

If one assumes \(\text{a)}\) then \(\text{b)}\) is equivalent to the existence of bounds \(d_1 > d_2 > 0\) with \(d_2 \leq \text{diam} (\sigma) \leq d_1\) for all \(\sigma \in K\). \(\text{a)}\) and \(\text{b)}\) are equivalent to the boundedness of the volumes from below and the diameters from above.

We call triangulations which satisfy the condition \(\text{a)}\) – \(\text{c)}\) uniform. Uniform triangulations are u.l.f.. A connection between combinatorial and analytical theory is given by the following fundamental theorem of Goldstein / Kuzminov / Shvedov (cf. [18]).

**Theorem 6.20** Let \(t: |K| \rightarrow M\) be a uniform triangulation and \(1 \leq p < \infty\). Then there exists a canonical topological isomorphism \(w_\ast\) (essentially induced by the Whitney transformation),

\[
w_\ast : H^{p,\ast}(K) \rightarrow H^{p,\ast}(M, g), \quad w_\ast : \overline{H}^{p,\ast}(K) \rightarrow \overline{H}^{p,\ast}(M, g).
\]

**Remark.** The \(p = 2\) version for the reduced case has been established by Dodziuk (cf. [4]).

Consider now \((M_1^n, g_1), (M_2^n, g_2)\) with \((I)\) and \((B_k)\) and a uniformly proper map \(f \in C^{\infty, k+1}(M_1, M_2)\).

**Proposition 6.21** Let \(t_i : |K_i| \rightarrow M_i, i = 1, 2\), be uniform triangulations. Then there exists a uniform triangulation \(K'_1\) which has bounded degree of subdivision and a simplicial approximation \(f' : K^1 \rightarrow K_2\) of \(f\) which is at \(L_2\)-chain level local.

**Theorem 6.22** Let \(K^n\) be an oriented u.l.f. combinatorial homology \(n\)-manifold. Then there exist isomorphisms

\[
D : H^{*,2}(K^n) \rightarrow H_{n-*2}(K^n) \quad \overline{D} : \overline{H}^{*,2}(K^n) \rightarrow \overline{H}_{n-*2}(K^n).
\]

Combining now 6.19 – 6.22, we obtain...
**Theorem 6.23** Assume \((M^n_i, g_i)\) with \((I)\) and \((B_k)\), \(k > \frac{n}{2} + 1\). Let \(f \in C^{\infty,k+1}(M_1, M_2)\), \(g \in C^{\infty,k+1}(M_2, M_1)\) uniformly proper homotopy equivalences, inverse to each other. Then \(f\) and \(g\) induce topological isomorphisms

\[
\begin{align*}
H^2_*(M_1, g_1) & \xrightarrow{\Phi} H^2_*(M_2, g_2) \\
\overline{H}^2_*(M_1, g_1) & \xrightarrow{\Phi} \overline{H}^2_*(M_2, g_2)
\end{align*}
\]

where \(\Phi, \Psi\) are induced by simplicial approximations of \(f, g, \Theta, \eta\) and \(w\).

\[\blacksquare\]

**Corollary 6.24**

Assume \((M^n_i, g_i)\), \(f, g\) as above, \(0 \leq q < n\). Then \(\inf \sigma_e(\Delta_q(M_1)|_{(\ker \Delta_q(M_1)^\perp)} > 0\) if and only if \(\inf \sigma_e(\Delta_q(M_2)|_{(\ker \Delta_q(M_2)^\perp)} > 0\).

**Proof.** Apply the analytical version of 5.8. Then the spectral gap exists for \(\Delta_q(M_1)\) if and only if \(H^{2,q}(M_1, g_1) = \overline{H}^{2,q}(M_1, g_1), H^{2,q+1}(M_1, g_1) = \overline{H}^{2,q+1}(M_1, g_1)\). But this holds if and only if it holds for \((M_2, g_2)\). \(\blacksquare\)

We will not discuss here the general theory of characteristic numbers for open manifolds, \(L^2\)-intersection theory and general duality. We only mention that for manifolds of bounded geometry duality holds from \(H^*_\text{uff}\) to \(H^*_\text{uff}\) and \(L^2\)-bounded duality in the \(L^2\)-case. This yields obstructions for the corresponding components to contain a manifold of bounded geometry.

We also defined homologies for the rel–components but refer to [8], [9], [10].
