The Journal of Antibiotics (2016) 69, 567–570; doi:10.1038/ja.2016.66; published online 15 June 2016

INTRODUCTION

Trans-acyltransferase polyketide synthases (trans-AT PKSs) construct biologically active polyketides, such as the antibiotic mupirocin, in an assembly line process catalyzed by collections of enzymatic domains termed modules. Each module of a trans-AT possesses an acyl carrier protein (ACP) and ketosynthase (KS) that, along with a separately-encoded acyltransferase (AT) domain, constitute the minimal trio of domains required for the extension of a covalently-bound intermediate.1,2 Further modifications at the α- and β-carbons of the polyketide are introduced by processing enzymes such as the methyltransferase (MT), ketoreductase (KR), dehydratase (DH) and enoylreductase (ER), depending on their inclusion within a module. This optional incorporation can be primarily credited for the vast chemical and functional diversity observed within polyketides.1,2

Unlike the embedded AT domains of cis-AT PKS pathways that deliver malonyl-CoA or methylmalonyl-CoA extender units to a single module, the discrete ATs of trans-AT PKSs deliver extender units to several modules. Since these ATs are primarily selective for malonyl groups, trans-AT PKSs employ embedded S-adenosyl methionine (SAM)-dependent MT domains to install methyl groups into polyketide backbones.1–3 Although SAM-dependent MTs constitute a well-studied superfamily of enzymes and are relatively common within trans-AT PKSs, a dearth of information exists for trans-AT MTs and PKS-embedded MTs in general. Only a few studies of MTs from select cis-AT PKSs and fungal highly reducing PKSs (HR-PKSs) have been reported.4–9 Analysis of a fungal HR-PKS responsible for the production of lovastatin revealed the kinetic preference of an embedded AT towards its native acyl-S-N-acetylcysteamine (NAC) substrate analog.1,2,9,10,11

To explore the selectivity of trans-AT MTs, we examined the methylation activity of excised MT domains from three well-known trans-AT pathways, responsible for the production of the antimicrobial agents bacillaene, dificidan and mupirocin (Figure 1), toward the acyl-S-NAC substrates 3-oxobutanyl-S-NAC (1), 3-oxopentanoyl-S-NAC (2) and 3-oxohexanoyl-S-NAC (3).12–14 (Figure 2a). This is the first account of the substrate specificity and activity of excised MT domains from trans-AT PKSs.

MATERIALS AND METHODS

S-adenosyl-methionine (Ark Pharm, Inc, Libertyville, IL, USA) was dissolved in 300 mM sodium phosphate buffer (pH 7.8) to a final concentration of 150 mM.

The DNA encoding DifMT1, DifMT6, DifMT13, BaeMT9, BaeMT14, MupMT1 and MupMT3 was amplified from the dif-AT gene cluster of Bacillus amyloliquefaciens FZB42 and the mupirocin gene cluster of Pseudomonas fluorescens 13525 and inserted into pGAY28b, a ligation-independent cloning vector constructed from pET28b (Supplementary Table S1).15 Escherichia coli BL21(DE3) transformed with the expression plasmid was inoculated from E. coli ed from BL21(DE3) genomic DNA and cloned and

purified as above (Supplementary Table S1). Reactions were supplemented with Pfs due to the potent inhibition of MTs by SAH.5

Compounds 1–3, 2-methyl-3-oxobutanyl-S-NAC (4), and 3-oxo-hexanoyl-S-NAC (6) were prepared according to reported protocols,16 as was 2-methyl-3-oxopentanyloxy-S-NAC (5).17

To determine MT activity reactions with substrates 1–3 (10 mM) contained 150 mM Tris-HCl, 100 mM NaCl, 20 mM SAM, 10% (v/v) glycerol, 20 μM Pfs, and 10 μM MT in a total volume of 200 μl. Reactions were run in parallel at 25 °C for ~16 h. Standards of 4, 5, and 6 at concentrations from 250 μM to 50 mM were added directly to injection solvent and HPLC peak areas were collected to provide standard curves for observable product formation.

To determine the linear region of MT kinetic data, reactions with substrates 1–3 (10 mM) contained 150 mM Tris-HCl, 100 mM NaCl, 20 mM SAM, 10% (v/v) glycerol, 20 μM Pfs and 10 μM MT in a total volume of 200 μl and were run in parallel at 25 °C and quenched at 0, 1, 2, 3, 4, and 5 h.

Reactions with substrates 1–3 (100 μM, 500 μM, 1 μM, 2.5 mM, 5 mM, 10 mM or 50 mM) contained 150 mM Tris-HCl, 100 mM NaCl, 20 mM SAM, 10% (v/v) glycerol, 20 μM Pfs, and 10 μM MT in a total volume of 200 μl. Reactions were run in parallel at 25 °C over a period of 1–3 h (MupMT1+1, 1 h; MupMT1+2, 2 h; MupMT1+3, 3 h; BaeMT9+3, 2 h; DifMT1+2, 2 h; DifMT1+3, 2 h) (Figures 2b–g). After completion, reactions were extracted with 1 ml of ethyl acetate. The organic layer was dried in vacuo and resuspended in methanol for HPLC analysis. Standard curves were generated by HPLC analysis of 60 μM, 300 μM, 600 μM, 1 μM, 3 mM and 6 mM injections of 4 and 200 μM, 1 μM, 2 mM, 5 mM, 10 mM and 20 mM injections of 5 and 6. Reactions for each set of substrate concentrations were performed in triplicate.

Product formation was quantified by absorbance with reverse phase HPLC resolution of reaction mixtures stopped at a fixed time-point with 0.1–50 mM substrate as well as full progress curves at 10 mM substrate (Supplementary Figure S10). Global fitting of both data sets to a reaction model using Kintek Explorer allowed determination of kcat/KM values for each enzyme/substrate pair (Table 1 and Supplementary Figure S1).18–20.

Figure 1 (a) Canonical α-methylation catalyzed by trans-AT PKS MTs. (b) α-branched and cognate MT domains of bacillaene, difficilin, and mupirocin. AT, acyltransferase; MT, methyltransferase; PKS, polyketide synthase. A full color version of this figure is available at The Journal of Antibiotics journal online.

HPLC analysis was performed with a tandem Waters 2707 autosampler and Waters 1525 binary HPLC pump (Milford, MA, USA) connected to a Waters 2998 photodiode array detector using a Varian Microsorb-MV C18 column (250 x 4.6 mm, 5 μm particle size, 100 Å pore size) and mobile phases consisting of water with 0.1% TFA (solvent A) and acetonitrile with 0.1% TFA (solvent B) with a solvent gradient of 5–100% B over 30 min at a flow rate of 1 ml min⁻¹. High-resolution MS measurements of methylated products were obtained by chemical ionization (ESI) with a VG analytical ZAB2-E instrument (Milford, MA, USA). Peak integrations were automated with a signal-to-noise cutoff of 5% peak area.

RESULTS AND DISCUSSION

Of the seven domains cloned, all produced soluble protein with the exception of MupMT3. In addition to several previously identified sequence motifs that distinguish between cis- and trans-AT MT domains, a trans-AT MT sequence alignment revealed an additional notable difference between these two classes of MT domain regarding their position within the module.21 In contrast to their cis-AT counterparts, trans-AT MTs are not embedded within the KR structural subdomain but are instead usually situated immediately after the KR domain and immediately before the ACP domain.22

In vitro assays of the excised MTs BaeMT9, DifMT1, and MupMT1 showed each to be capable of catalyzing the methylation of substrates 1, 2, and 3 to afford 4, 5, and 6 (Figure 2 and Supplementary Figure S2, Table 1). These results show that, at least when separated from their assembly lines, MTs are not highly substrate-specific. Other excised PKS enzymes (KR, DH, ER and thioesterase (TE)) also demonstrate broad substrate specificities.20–23 The low reaction rates of BaeMT9, DifMT1, and MupMT1 are suggestive that local substrate concentrations within the intact assembly line are required for optimal catalytic rates. While the conversions of 1 to 4 catalyzed by BaeMT9 and DifMT1 as well as 2 to 5 catalyzed by BaeMT9 were observed overnight, the percent conversions within the linear region (1–3 h) were too low to accurately report kinetic parameters using HPLC analysis (Supplementary Figures S5). The observed reaction rates for MTs are lower than those of other excised processing domains.
(for example, KR, DH or TE) toward NAC-linked substrates. Although DifMT1 and BaeMT9 demonstrated substrate affinities for 2 and 3, respectively (Table 1), a significant kinetic preference for a specific substrate was not observed from any of the investigated MTs.

The N-terminal MTs DifMT6, DifMT13, and BaeMT14 did not catalyze a detectable amount of methylation of 1, 2 or 3. Unlike the completely embedded MTs, N-terminal MTs may require additional components for activity, such as inclusion in their native polypeptide or interaction with the upstream PKS polypeptide.

The presented work demonstrates that, similar to the other processing domains excised from PKSs, excised trans-AT PKS MTs are capable of operating on thioester-bound polyketide substrates in vitro. These data disclose the initial investigation of the here-tofore unexplored MTs found throughout the trans-AT PKS landscape and provide insight into the catalytic activity of the

Figure 2 Saturation curves for (a) Substrates and products of MT reactions in this study, (b) MupMT1 and 1 after 1 h, (c) MupMT1 and 2 after 2 h, (d) MupMT1 and 3 after 3 h, (e) BaeMT9 and 3 after 2 h, (f) DifMT1 and 2 after 2 h, (g) DifMT1 and 3 after 2 h. Experimental data from saturation curves was globally fit to a fixed concentration time-course for enzyme-substrate pairs (Supplementary Figure S1).
