Nocardia farcinica
Immunocompetent
Disseminated brain abscess

**ABSTRACT**

*Nocardia farcinica* is a gram-positive, partially acid-fast, methenamine silver-positive aerobic actinomycete that is infrequently associated with nocardiosis. The relative frequency of *Nocardia farcinica* isolates in nocardiosis is unknown but thought to be under diagnosis. It is increasingly being recognized in immunocompetent patients.

We report a case of disseminated *Nocardia farcinica* causing brain abscess in a 55-year-old immunocompetent man who was successfully treated with long-term antibiotics.

The present report illustrates that early detection and treatment of disseminated *Nocardia farcinica* can lead to a good outcome.

**Introduction**

Disseminated Nocardiosis is an opportunistic infection that is usually seen in immunocompromised hosts. *Nocardia farcinica* is a rare cause of nocardiosis but is increasingly being recognized as a potential lethal infection in immunocompetent patients (1–3). This report describes a patient with disseminated infection due to *Nocardia farcinica*.

**Case presentation**

A 55-year-old man presented to the emergency room with a three week history of throbbing and persistent right occipital headaches radiating to his frontal region. The headaches were not associated with any aura, photophobia, nausea or vomiting. The patient also had recurrent complaints of fevers and nocturnal diaphoresis. After presenting to a walk-in clinic and diagnosed with a presumptive viral infection. No antibiotic medication was prescribed.

His past medical history included smoking and gastro-esophageal reflux disease. There was no history of any prior headaches, tuberculosis or exposure, positive tuberculin skin tests, syphilis, gonorrhea, chlamydia, human immunodeficiency virus (HIV), malignancies, hepatitis, recent surgeries, workplace exposure or recent travel.

His physical examination showed a healthy appearing man, hemodynamically stable with a high grade fever of 39.5°C. His neurological exam, cardiac exam, respiratory exam and abdominal exam were all normal.

Investigations revealed white blood cell count of 13.1 × 10<sup>9</sup>/L (with 87% polymorphonuclear cells, 4% monocytes, and 9% lymphocytes), hemoglobin 136 g/L, platelet count 367 × 10<sup>9</sup>/L and a normal serum chemistry panel including transaminases. His absolute CD4 count was 449 × 10<sup>3</sup> /L and his HIV serology was non-reactive. Chest radiograph however revealed wedge-shaped nodular opacity measuring 3.1 × 3.25 cm in the left upper lobe adjacent to the pleura (Fig. 1). A lumbar puncture showed 3065 × 10<sup>6</sup>/L of white blood cells (normal 0–5 × 10<sup>6</sup>/L), 1.1 mmol/L of glucose (normal 2.2–3.9 mmol/L) and 190 g/L of total protein (normal 0.12–0.6 mmol/L). Preliminary CSF cultures did not grow any organism. The patient was then started on ceftriaxone, vancomycin and ampicillin.

A computed tomography (CT) of the chest and abdomen with intravenous contrast revealed a large spiculated 2.8 × 4.5 × 3.7 cm subpleural mass in the lateral aspect of the left upper lung lobe and a smaller spiculated and eccentrically cavitated 1.4 cm nodule in the posterior and subpleural aspect of the lower lobe (Fig. 2). There was no hilar or mediastinal lymphadenopathy. Initial computed tomography of the head was normal but a follow up Multisequence Multiplanar Unenhanced Magnetic Resonance Image (MRI) of the head with gadolinium showed a T2 hypointense lesion involving the left head of the caudate nucleus with perifocal edema suspicious for a fungal abscess (Fig. 3).

The patient’s headaches and fever continued to persist so a computed tomographic guided biopsy of the large spiculated...
subpleural mass of the left upper lobe was performed as well as repeat lumbar puncture. Both the lung tissue biopsy and the repeated CSF fluid cultures grew beaded branching gram positive bacill. Molecular studies using the Multi-Locus sequence analysis (MLSA) identified the species as *Nocarida farcinica*. Further susceptibility testing showed the organism was susceptible to amoxicillin/clavulanic acid, imipenem, linezolid, moxifloxacin and trimethoprim/sulfamethoxazole (TMP-SMX) but resistant to ceftriaxone (Fig. 4).

Ceftriaxone, vancomycin and ampicillin were discontinued and the patient was treated initially with imipenem for six weeks followed by TMP-SMX for one year.

**Discussion**

We present a rare case of disseminated *Nocarida farcinica* originating from the lungs and causing a brain abscess in an immunocompetent patient.

Nocardiosis is an opportunistic infection causing localized or disseminated disease and caused by the soil-dwelling, weakly gram-positive aerobic actinomycete *Nocardi*a. It predominately presents as an acute, subacute or chronic pulmonary disease in immunocompromised hosts that can disseminate to any organ, forming abscesses [1]. *Nocardia asteroides* and *Nocardia brasiliensis* are the two species most frequently involved in human disease [2]. *Nocardia farcinica* is a gram-positive, partially acid-fast, methenamine silver-positive aerobic actinomycete infrequently

associated with nocardiosis [3]. However it can cause clinically aggressive and potentially lethal disseminated infections in immunocompromised patients. It is also known to be resistant to multiple antimicrobial agents. It is rarely reported as a cause of nocardiosis in immunocompetent hosts [4]. The relative frequency of Nocardia farcinica isolates in nocardiosis is unknown but thought to be underdiagnosed and is increasingly being recognized in immunocompetent patients [2].

The diagnosis of Nocardia farcinica requires the isolation and identification of the organism from tissue, culture specimen or both [3]. Since nocardia is a slow growing organism it may be difficult to detect the organism on hematoxylin and eosin (H & E) stain and acid-fast stain [5]. Usually gram and methenamine silver (GMS) stain is positive. Cultures of nocardia species can take up to five days or more to grow and PCR identification of the 16S ribosomal RNA of the organisms is rapid but not always available in all laboratories [6].

Nocardia Farcinica has specific drug susceptibility patterns. Nocardia Farcinica is resistant to most beta-lactam antibiotics, aminoglycosides but susceptible to amikacin [7,8]. Nocardiosis is treated usually with combinations of TMP-SMX, imipenem-cilastatin, moxifloxacin, amikacin, linezolid, minocycline or ciprofloxacin for a duration of six to twelve months depending on central nervous system involvement. The most commonly used antibiotic reported is TMP-SMX [9,10].

A literature search revealed very few reported cases of disseminated Nocardia farcinica in immunocompetent host, their treatment with antibiotics and outcomes (Table 1). Other cases of Nocardia farcinica brain abscess in immunocompetent patients have been reported in the literature [10,13–16]. Table 2 shows their treatments and outcomes.

After a year of treatment, the patient had complete resolution of his symptoms of headache, fever and night sweats. A repeated MRI of his head showed almost complete resolution of the left caudate nucleus abscess and a repeat CT scan of his chest showed an interval improvement in the size of his left upper lobe mass.

**Conclusion**

Nocardia farcinica is infrequently associated with nocardiosis especially in immunocompetent patients. It is however associated with very aggressive and lethal disseminated infections in immunocompromised patients. Early detection and treatment can lead to a successful patient outcome.

**Consent section**

Written informed consent was obtained from the patient for publication of this case report and accompanying images. A copy of the written consent is available for review by the Editor-in-Chief of this journal on request.

**Conflict of interest**

Authors have no conflict of interest to report.
