Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Dear Editor,

Since end of December 2019, a cluster of patients with pneumonia of unknown origin was reported from Wuhan, Hubei province, China. They shared a connection with the Huanan South China Seafood Market in Wuhan, and now it has been confirmed that the disease is caused by a novel coronavirus (provisionally named 2019-nCoV). As of today (February 14, 2020), 63935 cases have been confirmed in China. Currently, clinicians have found some atypical cases with positive chest CT findings may present with negative results of RT-PCR for 2019-nCoV. The timely diagnosis, isolation and treatment of these patients will help control the further spread of 2019-nCoV.

We report a 58-year-old male who was admitted to the hospital with a 1-day history of fever, sore throat and fatigue 5 days after visiting Wuhan, China (the epicenter of the 2019 Novel Coronavirus Pneumonia outbreak) [1]. Physical examination of the lungs at admission was normal. Laboratory studies demonstrated the white blood cell count (4.3×10⁹/L) and blood procalcitonin level were also normal. The erythrocyte sedimentation rate was slightly increased at 23 mm/h (normal range, 0~20 mm/h). A swab test and chest CT scanning were performed. Chest CT images illustrated multiple patchy, cloud-like high-density shadows in the dorsal segment of the right lower lobe (Figure a & c). Three real-time fluorescence polymerase chain reaction (RT-PCR) assay of the oropharyngeal swab specimens were negative for the 2019-nCoV nucleic acid.

A repeat chest CT performed 4 days after admission displayed that the range of patchy turbidity high-density shadows in the lower lobe of the right lung was significantly enlarged, and turbidity high-density shadows also appeared in the outer zone of the left lower lobe (Figure b & d ). Finally, the fourth RT-PCR 2019-nCoV nucleic acid assay was positive.
Currently, clinicians have found some cases with positive chest CT findings may present with negative results of RT-PCR for 2019-nCoV. Although this patient's multiple specimen tests were negative, repeat chest CT showed a great progression of cloud-like high-density shadows in both lungs compared to the previous chest CT. The imaging characteristics of 2019-nCoV pneumonia may be bifocal extra-zonal distribution, bilateral, multifocal [2-3]. With typical clinical presentation and a clear epidemiological history, 2019-nCoV infection may be strongly suspected when chest CT has the characteristics of viral pneumonia despite negative RT-PCR results. In these cases, repeat oropharyngeal swab testing and patient isolation should be carefully considered.

Contributors W-DH obtained and analysed the clinical data and made the figure. We all contributed to editing the figure, and writing and editing the manuscript. Written consent for publication was obtained from the patient.

Competing interests None declared.
