The high background value of cadmium (Cd) in the *Panax notoginseng* planting soil is the main reason for the Cd content in *P. notoginseng* exceeding the limit standards. The main goal of this study was to reveal the mechanism by which potassium (K) reduces Cd accumulation in *P. notoginseng* from the perspective of the influences of soil microbial communities on soil pH, total organic matter (TOM) and cation exchange capacity (CEC). Pot experiments were conducted to study the effects of different types and amounts of applied K on the Cd content in *P. notoginseng*, and on the soil pH, TOM, CEC, and bioavailable Cd (bio-Cd) content in soil. Field experiments were conducted to study the effects of K$_2$SO$_4$ fertilizer on the microbial community, and its correlations with the soil pH, TOM and CEC were analyzed. A moderate application of K$_2$SO$_4$ (0.6 g·kg$^{-1}$) was found to be the most optimal treatment for the reduction of Cd in the pot experiments. The field experiments proved that K fertilizer (K$_2$SO$_4$) alleviated the decreases in pH, TOM and CEC, and reduced the content of bio-Cd in the soil. The application of K fertilizer inhibited the growth of Acidobacteria, but the abundances of Mortierellomycota, Proteobacteria and Bacteroidetes were promoted. The relative abundances of Acidobacteria and Proteobacteria in the soil bacteria exhibited significant negative and positive correlations with pH and CEC, respectively. In contrast, the relative abundance of Mortierellomycota was found to be positively correlated with the pH, TOM and CEC. The bio-Cd content was also found to be positively correlated with the relative abundance of Acidobacteria but negatively correlated with the relative abundances of Proteobacteria and Mortierellomycota. The application of K fertilizer inhibited the abundance of Acidobacteria, which alleviated the acidification of the soil pH and CEC, and promoted increase in the abundances of Mortierellomycota, Proteobacteria and...

HIGHLIGHTS

- K fertilizers can change the composition and abundance of microbial community in soil.
- Soil microorganisms were found to mitigated decreases in the soil pH, TOM, and CEC.
- The bio-Cd content can be reduced by improving the soil pH, TOM, and CEC.

INTRODUCTION

The genuine producing area of *Panax notoginseng* (Burk.) F. H. is Yunnan Province, China (Yang et al., 2018), which generates approximately 98% of the *P. notoginseng* medicinal materials on the Chinese market (Liu, 2019). However, Yunnan Province accounts for 46% of China’s Cd production (Liu et al., 2016). Its resulted in exceeding the standard rate by 35% and 23% of *P. notoginseng* planting soils and medicinal material, respectively (Ou et al., 2016; Shi et al., 2019). The ability to protect *P. notoginseng* from Cd has drawn considerable attention from consumers and regulatory departments (Lin et al., 2014). Thus, there is a need to develop a low-cost and high-efficiency Cd-blocking technology for *P. notoginseng* as well as to elucidate the underlying mechanisms by which Cd can be blocked.

Lowering the bioavailable Cd (bio-Cd) content in the soil is currently the main method for the reduction of the amount of Cd absorbed by plants (Guwei et al., 2010). The soil pH, organic matter, cation exchange capacity (CEC) and other soil physical and chemical properties strongly influence on the bioavailability of heavy metals in the soil (Yuan, 2014) and thus affecting the migration of heavy metals from soil to crops (Huang et al., 2012). An increase in pH leads to a corresponding rise in OH⁻ levels and improves the ability of oxide colloids to adsorb and bind heavy metals. As a result, the soil adsorptive capacity for Cd²⁺ increases, thereby increasing the amount of Cd precipitation in the soil (Ardestani and Van Gestel, 2013; Hong et al., 2014). As the soil CEC increases, the soil's adsorption and retention of heavy metal cations increases, and its specific adsorption of anions weakens, resulting in a decrease in the bioavailability of heavy metals (e.g., Cd, Pb, Hg) in the soil (Chen et al., 2018). An increase in total organic matter (TOM) can increase pH in the soil and the solid organic matter adsorption of heavy metals (Belay et al., 2002). These changes can also decrease the exchangeable heavy metal content (Zeng et al., 2011).

Soil microorganisms can decompose organic matter and alter the TOM content (Neumann et al., 2014). Yang et al. (2011) found that bacterial biomass in orchard soil exhibited a significant positive correlation with soil organic matter. Soil microorganisms also significantly interacted with pH. Sait et al. (2006) found a significant negative correlation between colonial development in Acidobacteria and the soil pH. The number of soil fungi interacted with the soil CEC, pH, and available K content, and was significantly positively correlated with the available K content and CEC (Zhang et al., 2011). Therefore, soil microorganisms are an important index for the evaluation of the evaluating soil pH, TOM, and CEC (Sanusi, 2015).

Potassium is often considered as a quality element (Radulov et al., 2014). Simultaneously, the application of K as a fertilizer can reduce the exchangeable lead content in wheat planting soil, thus reducing the inhibition of the increase of the dry weight (Chen et al., 2007a,b). Zhao et al. (2004) found that K₂SO₄ fertilizer could decrease the carbonates fraction of Cd [F(Carb)] and the exchangeable fraction of Cd [F(EXC)] in wheat planting soil, resulting in the reduction of the Cd content in wheat. Wang et al. (2017) indicated that KHCO₃ fertilizer could reduce the Cd content in tobacco and alleviate Cd toxicity during growth. Thus, it is evident that K plays an important role in the reduction of the bio-Cd content in the soil, thereby reducing its accumulation in plants.

Duan et al. (2015) demonstrated that applying an appropriate amount of K fertilizer could also improve the diversity of fungal species in soil by restricting the growth of certain fungi and effectively preventing the over propagation of pathogenic fungi. Jia et al. (2004) proved that K fertilizers promoted the growth of soil microorganisms and contributed to the mineralization of the soil organic matter in buckwheat planting soil. In the present research, it was hypothesized that K fertilization can indirectly improve soil physical and chemical properties indirectly by influencing the soil microorganisms. Consequently, the bio-Cd content was found to be reduced in the soil. This process is a key mechanism for the reduction of the accumulation of Cd in *P. notoginseng* under the application of K fertilization. However, there currently exists no direct evidence to support this hypothesis.

Accordingly, pot experiments and 2-year field experiments were performed to explore the effects of different K fertilizers and application amounts on the soil on pH, CEC, TOM, soil microorganisms, and Cd content in *P. notoginseng*. The amount of K fertilizer applied in the cultivation of *P. notoginseng* was optimized, and soil improvement and utilization were combined to promote the reduction of Cd in *P. notoginseng.*

MATERIALS AND METHODS

Pot Experiments

Pot experiments were conducted from May 5 to September 5 in 2017, and the experimental site was located in faculty of life science and technology of Kunming university of science and technology (E 102.51, N 24.50, altitude 1982 m). Main environment of the greenhouse was as follows: soil moisture, 33–48%; air humidity, 35–82%; daytime temperature, 12–29°C; night temperature, 8–18°C; sunshine duration, 9–11 h.

Two-year-old P. notoginseng was planted in the plastic pot (70 × 40 × 28 cm) with 18 kg soil. The soil was the same as that of the greenhouse of tillage layers (0–20 cm). The soil was dried and crushed, separated from weeds, rocks and other debris, and then sifted and reserved. According to the conclusion of Li et al. (2015), 10 mg·kg⁻¹ Cd treatment was set up. Under the same K treatment level, the amount of K input by different types of K fertilizer was consistent. Simultaneously, KCl and K₂SO₄ were adopted, respectively. Three K (K₂O) levels were used as follows, low application amount: 0.171 g·kg⁻¹ (KCl1), 0.2 g·kg⁻¹ (K₂SO₄1); medium application amount: 0.513 g·kg⁻¹ (KCl2), 0.6 g·kg⁻¹ (K₂SO₄2); high application amount: 1.026 g·kg⁻¹ (KCl3), 1.2 g·kg⁻¹ (K₂SO₄3), respectively. The treatments were as follows: CK (control), Cd, Cd + KCl1, Cd + K₂SO₄1, Cd + KCl2, Cd + K₂SO₄2, Cd + KCl3, Cd + K₂SO₄3.

Eight treatments were conducted, every treatment was repeated three times (three pots), every pot planted eight seedlings. Nitrogen (carbamide) and phosphate (P₂O₅) fertilizers were used at 0.30 and 0.10 g·kg⁻¹, respectively. All of fertilizers were applied as basal fertilizer. Cd was soluted in distilled water, while basal fertilizers were mixed up with dry soil, and then added to the pots.

Field Experiments

In Qiubei County, Wenshan City, Yunnan Province, field experiments were performed from January to November of 2018. The basic soil physical and chemical properties of Malishu was as follows: pH, 5.76; TOM, 5.63 g·kg⁻¹; CEC, 7.33 c mol·kg⁻¹; total K 24.28 g·kg⁻¹; total P, 0.52 g·kg⁻¹; total N, 1.12 g·kg⁻¹; alkali-hydrolyzed N 54.00 mg·kg⁻¹; available P 1.15 mg·kg⁻¹; and available K 83.00 mg·kg⁻¹. The basic soil physical and chemical properties of Malishu was as follows: pH, 5.88; TOM, 5.58 g·kg⁻¹; CEC, 7.69 c mol·kg⁻¹; total K 24.71 g·kg⁻¹; total P, 0.35 g·kg⁻¹; total N, 1.04 g·kg⁻¹; alkali-hydrolyzed N 53.20 mg·kg⁻¹; available P 1.08 mg·kg⁻¹; and available K 87.00 mg·kg⁻¹. The planting soil of P. notoginseng was red soil.

According to the optimum application type and amount of K fertilizer in the pot experiments, the optimum application amount of K fertilizer (K₂SO₄, 300 kg·ha⁻¹ both in 2018 and 2019) in field experiment were performed according to the soil weight conversion of 20 cm deep plow layer. Simultaneously, the amount of K fertilizer (15 kg·ha⁻¹ both in 2018 and in 2019) was set as the control. The treatments were as follows: K₁₅, K₃₀₀. All groups were repeated three times. The 15 kg·ha⁻¹ (K₁₅) and 300 kg·ha⁻¹ (K₃₀₀) were used as the application amounts.

Determination of Cd Content

Determination of Cd Content in P. notoginseng

According to Shi et al. (2019), microwave digestion with HNO₃–H₂O₂ was used to digest the Cd content in P. notoginseng. Dried sample (0.20 g) was accurately weighed (accurate to 0.0001 g) and placed in the Teflon dissolving cup. Then, 10 ml 65% HNO₃ was added, and left overnight for pre-reaction and when 2 ml 30% H₂O₂ was added. Until the reaction was stable, the sample cup was covered, placed it in a high-pressure tank, and then putting into a microwave sample dissolving device. The step temperature increased to 180°C for 25 min (the power of the single tank was 600 w). While the sample was dissolved, the temperature was reduced to room temperature. The sample was transferred to a 10 ml volumetric flask, water was used to scale, and the sample was shaken well. And a blank control was made at the same time. The Cd content was determined by inductively coupled plasma atomic emission spectrometry (ICP-AES).

Speciation of Cd in the Soil and Determination of Cd Content

The soil Cd classification adopted the improved Tessier A five-step extraction method (Tessier et al., 1979). Soil was divided into the following five components:

F(Exc): The sediment was continuously extracted for 1 h with 8 ml 1 M MgCl₂ solution (pH = 7.00), then, centrifuged at 4000 r min⁻¹ for 10 min and filled to constant volume to be measured.

F(Carb): The residue from previous was continuously extracted for 5 h with 8 ml 1 M NaAc solution (pH = 5.00), then 4000 r min⁻¹ for 10 min centrifuged and made it constant volume to be measured.

F(Fe-MnOX): The residue from previous was continuously extracted for 6 h with 25% HAC solution of 20 ml 0.04 M NH₄OH·HCl at 96 ± 3°C; then, centrifuged at 4000 r min⁻¹ for 10 min and filled to constant volume to be measured.

F(OM): The residue from previous was continuously extracted for 2 h with 3 ml 0.02 M HNO₃ and 5 ml 30% H₂O₂ solution (pH = 2.00) at 85 ± 3°C, continuously extracted for 3 h with 3 ml 30% H₂O₂, and cooled to room temperature; then, continuously extracted for 30 min with 5 ml 20% HNO₃ of 3.20 M NH₄AC; then, centrifuged at 4000 r min⁻¹ for 10 min and filled to constant volume to be measured.
F(RES): The residue from previous was digested with HF-HClO₄.

Cd was analyzed using inductively coupled plasma mass spectroscopy (ICP-MS, X Series 2, Thermo Fisher Scientific, United States).

**Determination of Soil pH, TOM, and CEC**
Soil pH determination method refers to ISO 10390:2005 standard, which determined with a pH meter (FE20, Mettler, China) after mixing soil and water at a 1–2.5 ratio.

TOM determination method refers to ISO 23470–2011 standard, 0.10–0.50 g (0.001 g) soil sample was weighed, then mixed with 0.10 g AgSO₄, 5 ml 0.80 M K₂Cr₂O₇ solution and 5 ml H₂SO₄, then heated to 180°C for 5 min, and titrated with 0.20 M (NH₄)₂ Fe (SO₄)₂ standard solution.

CEC determination method refers to ISO 14235–2009 standard, 2.00 g soil sample was weighed, mixed with 60 ml 1 M ammonium acetate solution, centrifuged at 3000 r min⁻¹ for 5 min, centrifugation was repeated until supernatant had no calcium ions. Then, 60 ml 95% ethanol was added and centrifuged, the above steps were repeated until supernatant had no ammonium ions. The solution was distilled by Kjeldahl apparatus and titrated with HCl standard solution.

**Statistical Analysis**
Data were processed with Microsoft Excel software 2018, Graphpad Prism 7.0 SPSS 24.0 were applied to fit the curves and analyze statistics, respectively. Duncan’s multiple range tests of one-way ANOVA were used to analyze data for separating means. When P < 0.05, differences were considered significant. The Spearman correlation analysis was used to assess the association of the relative abundance of microbial community with pH, TOM, CEC, and bio-Cd.

**RESULTS**
**Effect of K Fertilizer on Cd Content in P. notoginseng in the Pot Experiments**
The results of the pot experiment demonstrated that the Cd accumulation in *P. notoginseng* roots decreased under different types of K fertilizer treatments (Figure 1). Relative to that of Cd the treatment, the Cd content in the main root under the KCl2 and K₂SO₄₂ treatments decreased by 28 and 44%, respectively; the Cd content in the rhizome decreased by 40 and 47%, respectively; and the Cd content in the rootlets decreased by 41 and 51%, respectively. The K₂SO₄ treatment resulted in the largest reduction in Cd accumulation and was thus adopted in the subsequent experimental treatments.

Relative to that under the Cd treatment, the Cd content in the main root under the K₂SO₄₁, K₂SO₄₂, and K₂SO₄₃ treatments decreased by 46, 44, and 44%, respectively; that in the rhizome decreased by 47, 47, and 50%, respectively; that in the rootlets decreased by 47, 51, and 52%, respectively (Figure 1). The reduction in the accumulation of Cd in *P. notoginseng* under the moderate K fertilizer treatment was similar to that under the high K fertilizer treatment. Therefore, 0.6 g kg⁻¹ K₂SO₄ was converted into an application of 300 kg ha⁻¹ for the subsequent field verification experiment.

**Effect of K Fertilizer on the pH, TOM, and CEC of P. notoginseng Planting Soil in the Pot Experiments**
In the pot experiments, low K fertilizer treatments significantly improved the soil pH and TOM, but different types of K fertilizer treatments did not significantly affect the soil pH (Figures 2A,D,G). A moderate amount of K fertilizer was found to significantly promote the increase of the soil pH, TOM, and CEC. The pH levels of the soil under the KCl2 and K₂SO₄₂ treatments increased by 5 and 6%, respectively; the TOM increased by 18 and 27%, respectively; and the CEC increased by 5 and 7%, respectively (Figures 2C,E,H).
Effect of K Fertilizer on the Bio-Cd Content in *P. notoginseng* Planting Soil in the Pot Experiments

Compared with the Cd treatment, all K fertilizer treatments reduced the soil bio-Cd content in the soil (Figure 3). When a moderate amount of K fertilizer was applied, the bio-Cd contents under the KCl2 and K2SO42 treatments decreased by 16 and 23%, respectively.

Effect of K2SO4 on Cd Accumulation in *P. notoginseng* in the Field Experiments

Relative to that under the K15 treatment, the Cd content in the main root under the K300 treatment decreased by 47%, that in the rhizome decreased by 41%, and that in the rootlets decreased by 23% in 2018; additionally, the Cd content in the main root decreased by 52% in 2019 (Figure 4). Regarding the K300 treatments in 2018 and 2019, the Cd content in the main root and rhizome were 0.20 (2018), 0.15 (2019) and 0.25 (2018), 0.25 (2019) mg·kg⁻¹, respectively, both of which were within the WM-T2-2004 standard (WM-T2-2004, 2004) (0.3 g·kg⁻¹).

Effect of K2SO4 on the pH, TOM, and CEC of *P. notoginseng* Planting Soil in the Field Experiments

Relative to those under the K15 treatment, the pH, TOM, and CEC of the soil under K300 treatment were increased by 14, 8, and 21%, respectively, in 2018; in 2019, the values of these increments were 13, 8, and 26%, respectively (Figure 5).

Effect of K2SO4 on Microbial Community Composition in *P. notoginseng* Planting Soil in the Field Experiments

The sequences were submitted to the SRA (Sequence Read Archive) at the National Center for Biotechnology Information (NCBI) under the accession number PRJNA626539 for 16S sequences (B1–B12) and ITS sequences (F1–F12). At the phylum level, 25 bacterial phyla and 10 fungal phyla were detected in eight samples under the two treatments. The bacterial communities in all treated samples primarily consisted of Proteobacteria, Acidobacteria, Gemmatimonadetes, Actinobacteria, Bacteroidetes, and other dominant phylum-level species with relative abundances of more than 5%. The fungal communities were primarily composed of Ascomycota, Mortierellomycota, and other dominant phylum-level species. The relative abundances of Proteobacteria and Verrucomicrobia increased under the K2SO4 treatment. The relative abundances of Proteobacteria significantly increased by 12% (2018) and 7% (2019), those of Acidobacteria significantly decreased by 13% (2018) and 6% (2019); and those of Chloroflexi significantly decreased by 17% (2018) and 21% (2019) (Figures 6A, 7A). The relative abundances of Mortierellomycota significantly increased by 208% (2018) and 513% (2019), whereas those of Ascomycota significantly decreased by 22% (2018) and 21% (2019) (Figures 6D, 7D).

Moreover, 65 bacterial classes and 23 fungal classes were detected in this study. The relative abundances of Acidobacteria decreased by 45% (2018) and 30% (2019) with the application of K2SO4 (Figures 6B, 7B). The relative abundances of Mortierellomycetes increased by 208% (2018) and 513% (2019), whereas those of Sordariomycetes significantly decreased by 22% (2018) and 23% (2019) (Figures 6E, 7E). A total of 348 bacterial genera (Figures 6C, 7C) and 118 fungal genera (Figures 6F, 7F) were detected in this study.

Correlation Analysis of Microbial Community Composition, pH, TOM, and CEC of *P. notoginseng* Planting Soil Under Different K2SO4 Treatments in the Field Experiments

At the phylum level, the relative abundances of Proteobacteria and Planctomycetes in the soil bacteria showed significant positive correlations with the pH and CEC, whereas the relative...
FIGURE 2 | Effect of different types and application amounts of K on pH, TOM, and CEC. (A,D,G) Denoted low application amount, KCl1:0.171, K$_2$SO$_4$1:0.2 g·kg$^{-1}$; (B,E,H) denoted medium application amount, KCl2:0.513, K$_2$SO$_4$2:0.6 g·kg$^{-1}$; (C,F,I) denoted high application amount, KCl3:1.026, K$_2$SO$_4$3:1.2 g·kg$^{-1}$. Different lowercase letters indicate the means are significantly different at P < 0.05.

FIGURE 3 | Effect of different types and application amounts of K on Bio-Cd content in P. notoginseng planting soil. (A) denoted low application amount, KCl1:0.171, K$_2$SO$_4$1:0.2 g·kg$^{-1}$; (B) denoted medium application amount, KCl2:0.513, K$_2$SO$_4$2:0.6 g·kg$^{-1}$; (C) denoted high application amount, KCl3:1.026, K$_2$SO$_4$3:1.2 g·kg$^{-1}$. Bio-Cd content is the sum of F(EXC) and F(Carb) Cd.
abundances of Chloroflexi exhibited a negative correlation with pH and CEC in both 2018 and 2019 (Table 1). The relative abundance of Mortierellomyctota was found to exhibit significant positive correlations with the pH and CEC in the soil, whereas the relative abundance of Ascomycota exhibited a negative correlations with the pH, TOM, and CEC in the soil in 2018 and 2019.

At the class level, the relative abundance of Acidobacteria in the soil bacteria was negatively correlated with the pH and CEC in 2018 and 2019. Moreover, the relative abundances of Verrucomicrobia (2018) and Alphaproteobacteria (2018, 2019) respectively exhibited significant positive correlations with the pH and CEC, respectively. The relative abundance of Mortierellomycetes was positively correlated with the TOM, whereas the relative abundances of Sordariomycetes (2018, 2019) were negatively correlated with the pH and CEC of the soil (Table 2).

Redundancy analysis of dominant genus-level species of bacteria and the pH, TOM and CEC in *P. notoginseng* planting soil was conducted (Figure 8). The first ordination axis in Figures 8A,C explained 34% (2018) and 59% (2019) of the dominant genus-level species of soil bacteria, whereas the second ordination axis explained 19% (2018) and 22% (2019) of the same. This indicates that the amount of K$_2$SO$_4$ fertilizer was positively correlated with the pH, TOM, and CEC. The correlation P-values of the correlations between Holophaga (2018, 2019), Candidatus_Solibacter (2018), Bradyrhizobium (2018), Pseudolabrys (2019), and TOM were all less than 0.05 (Figure 8), indicating that the relative abundances of the aforementioned communities significantly affected the TOM content of the soil.

The first ordination axis in Figures 8B,D explained 22% (2018) and 57% (2019) of the variation in the dominant genus-level species of soil fungi, and the second ordination axis explained 16% (2018) and 25% (2019). The correlation P-values of the correlations between Mortierella (2018, 2019), Humicola (2018), Lecanicillium (2018), and Plectosphaerella (2019), and the pH and CEC were all less than 0.05 (Figure 8), indicating that the relative abundances of these communities significantly affected the pH and CEC of the soil.
FIGURE 6 | Effect of different amounts of K$_2$SO$_4$ on the community composition and relative abundance of Bacteria (A, Phylum; B, Class; C, Genus), Fungi (D, Phylum; E, Class; F, Genus) in *P. notoginseng* planting soil in 2018 (K$_{15}$, 15 kg·ha$^{-1}$; K$_{300}$, 300 kg·ha$^{-1}$).

FIGURE 7 | Effect of different amounts of K$_2$SO$_4$ on the community composition and relative abundance of Bacteria (A, Phylum; B, Class; C, Genus), Fungi (D, Phylum; E, Class; F, Genus) in *P. notoginseng* planting soil in 2018 (K$_{15}$, 15 kg·ha$^{-1}$; K$_{300}$, 300 kg·ha$^{-1}$).
by contrast, the bio-Cd content was found to be negatively correlated with pH, TOM and CEC in the soil fungi. (2018, 0.781**; 2019, 0.913*), but positively correlated with Ascomycota in 2018 (0.781*) and 2019 (0.913*).

At the phylum level, the bio-Cd content found to be positively correlated with Acidobacteria (2018, 0.927**; 2019, 0.945**), but negatively correlated with Verrucomicrobiae (2018, −0.781*) and Gammaproteobacteria (2019, −0.917** in the soil bacteria. Moreover, the bio-Cd content was found to positively correlated with the relative abundance of Sordariomycetes (2018, 0.781*; 2019, 0.920**), but negatively correlated with Mortierellomycetes (2018, −0.732*; 2019, −0.960*) in the soil fungi.

**DISCUSSION**

The bio-Cd content represents the portion of Cd in the soil that can be absorbed and utilized by plant. The pH, TOM, and CEC have been identified as the main factors that affect the
bioavailability of heavy metals in soil (Li and Song, 2003; Liang et al., 2013), and can be significantly regulated by fertilization. Agbede et al. (2010) found that the application of NPK mixture fertilizers can improve the pH and organic carbon content of yam (Dioscorea rotundata Poir) planting soil. K fertilizer can regulate the functional groups of acidic substances in tobacco planting soil and chelate heavy metal ions by adsorption and can thereby lowering the Cd activity and bio-Cd content in soil (Wu et al., 2012).

In the present study, pot experiments demonstrated that increases in the amount of applied K fertilizer significantly improved the pH, TOM, and CEC in P. notoginseng planting soil (Figure 2), resulting in a significant decrease in the bio-Cd content in the soil (Figure 3). The field experiments also verified the aforementioned results (Figures 5, 9). The results indicated that pH, TOM, and CEC reduction were ameliorated under the K fertilizer treatment, reducing the bio-Cd content in the planting soil and ultimately reducing the migration of Cd from the soil to P. notoginseng.

Fertilization can also affect the compositions, abundances and activities of soil microbial species. Jiang (2017) found that N fertilizer could change bacterial soil into fungal soil and decrease the biomass and abundance of soil microbial communities. Zhang and Xu (2014) demonstrated that K

**FIGURE 8** | RDA analysis of soil microbial community [A, bacteria (2018); B, fungi (2018); C, bacteria (2019); D, fungi (2019)] at the genus level and soil pH, TOM, and CEC in P. notoginseng planting soil under different K₂SO₄ treatments.
fertilizer (carbon enzyme K) could reduce the abundance and diversity of microbial communities in tomato planting soil. The application of K fertilizer can promote increases in soil nutrients and thereby lead to rapid increases in the abundances of microbial species that require large amounts of nutrients (Jia et al., 2004). Correspondingly, the application of K fertilizer can also reduce the abundances of microbial species that do not require large amounts of nutrients (Jia et al., 2004).

Essel et al. (2019) found a significant negative correlation between the abundances of bacteria, such as Holophagae, and pH in a 2-year spring wheat–pea rotation soil annually. In this study, the relative abundance of the class Acidobacteria from the phylum Acidobacteria in P. notoginseng planting soil bacteria was found to be negatively correlated with the soil pH and CEC (Table 2). This pattern most likely resulted from the fact that most bacteria in Acidobacteria are acidophilic. However, increases in the application of K fertilizer inhibited the proliferation of the acidophilic population and thereby delayed decreases in the soil pH. Zhang et al. (2019) also indicated that the pH and TOM were significantly correlated with bacterial community abundance and that the pH was significantly correlated with fungal community composition, such as the abundance of Mortierellomycota.

The relative abundance of Mortierellomycota in P. notoginseng planting soil fungi was found to be positively correlated with the pH, TOM, and CEC (Table 1). This pattern can likely be attributed to the participation of Mortierellomycota in the mineralization of soil organic matter for the decomposition of crop residues into the soil and organic matter in organic fertilizers. Thus, the TOM content raised as the abundance of Mortierellomycota increased. Proeobacteria and Bacteroidetes belong to the richness groups, which can promote the mineralization of organic matter. Liu (2019) found that there are positive correlations of Proteobacteria and Bacteroidetes with the soil carbon availability. The present study found that the abundances of Proteobacteria and Bacteroidetes both increased as the amount of applied K fertilizer increased, which promoted the accumulation of the TOM (Table 1). This pattern shows that the abundances of Proteobacteria and Bacteroidetes in the soil were promoted by K treatment, which facilitated the increases in the TOM.

Yao et al. (2019) determined that the bio-Cd content was significantly correlated with the diversity and abundance of microbial communities. In the present study, it was observed that the bio-Cd content was positively correlated with the soil pH and CEC (Table 3). This correlation was likely due to the fact that the bio-Cd content was positively correlated with the soil pH and CEC (Table 3).
relative abundance of the class Acidobacteria from the phylum Acidobacteria, but negatively correlated with the Proteobacteria and Mortierellomycota in the soil (Table 4). Therefore, as the amount of K fertilizer applied increased, the relative abundances of the dominant soil microbes in the community changed, thereby mitigating reductions in the pH, TOM, and CEC in the soil. As a result, the bio-Cd content in the soil and Cd content in P. notoginseng were reduced (Figures 1, 4). According to traditional theories, K can change the bio-Cd content by altering the soil physical and chemical properties. However, the present study suggests another possibility: namely, that the effects of K on the bio-Cd content may be mediated by its effect on soil microorganisms, which, in turn, alter pH, TOM, and CEC.

The reduction of the Cd content by K may be achieved by (i) decreasing the bio-Cd content in soil via absorption via crops and by (ii) reducing the capability of crops to uptake Cd. Non-selective cation channels play a substantial role in root Cd uptake. This process is driven by the electrochemical gradient for Cd$^{2+}$ on both sides of the plasma membrane. The membrane potential (between $-70$ and $-90$ mV) is often very close to the Nernst potential for K (available K, $-70$ mV); consequently, apoplast (soil) K$^+$ availability is increased, leading to membrane depolarization. Thus, reduced Cd accumulation in plants may also be caused by the weaker electrical gradient across the plasma membrane. However, these hypotheses require further verification.

CONCLUSION

A moderate K$_2$SO$_4$ treatment (pot experiment, 0.6 g kg$^{-1}$; field experiment, 300 kg ha$^{-1}$) provides the most optimal reduction of Cd accumulation in P. notoginseng. As the amount of applied K fertilizer increased, the relative abundances of Proteobacteria and Bacteroidetes increased, which promoted the accumulation of TOM; in addition, decreases in Acidobacteria alleviated the acidification of the soil. Such changes in these aforementioned soil microorganisms improved the pH, TOM, and CEC, which reduced the bio-Cd content in the soil and, in turn, the accumulation of Cd in the P. notoginseng roots was significantly reduced.
