Late-stage and strain-accelerated oxidation enabled synthesis of haouamine A†

Kun Ho (Kenny) Park, Antonio Rizzo and David Y.-K. Chen *

Herein we report a new synthetic entry to the strained cyclophane alkaloid natural product, haouamine A. The successful strategy featured a rhodium-catalyzed diazo-insertion reaction to install the all-carbon quaternary center and a rhodium-catalyzed intramolecular aziridination reaction to establish the nitrogen-bearing stereocenter, of the target molecule. Most notably, a late-stage, site-selective and strain-accelerated oxidation of a “deoxygenated” macrocyclic intermediate was successfully implemented, and in doing so provided a novel solution to the infamous biphenol cyclophane system of haouamine A.

Introduction

Strained cyclophanes are intriguing structural motifs with unusual physical properties, chemical reactivities, and methods for their preparation. Due to the strain imposed by the macrocyclic framework, the constituent aryl ring(s) within the cyclophane often experiences stress that leads to a distortion from planarity. Consequently, one of the most common tactics for the construction of strained cyclophanes exploits a conformational flexible “masked” aryl precursor bearing sp3 hybridized carbon center(s) for the macrocyclization event, followed by an aromatization-driven generation of the aryl ring(s) to render the targeted strained cyclophane system. In two instructive examples, Baran and co-workers disclosed contrasting approaches in their first syntheses of the indeno-tetrahydropyridine natural product, haouamine A (1, Scheme 1). In their first-generation synthesis, an intramolecular [4 + 2] cycloaddition followed by an enthalpic and entropic driven retro-[4 + 2]aromatization event successfully delivered the strained cyclophane system of haouamine A for the first time. A second-generation synthesis followed shortly where an intramolecular N-alkylation of a cyclohexenone precursor bearing sp3 hybridized carbon centers, followed by oxidative aromatization, rendered a more practical solution. In view of this state of affairs, we hypothesized a “late-stage” oxidation of a “deoxygenated” macrocyclic precursor (2) may provide an alternative solution to the biphenol cyclophane system of haouamine A (Scheme 2a). While this strategic maneuver benefits from greatly simplified synthetic precursors and broadens the selection of synthetic transformations for their preparation, site-selectivity of this unprecedented late-stage oxidation/oxygenation is expected to pose a serious challenge. Furthermore, we also envisaged the application of two rhodium-catalyzed processes ((a) diazo-insertion* and (b) intramolecular aziridination; Scheme 2b) starting from two readily accessible building blocks 4 and 5 to provide a novel
Scheme 2 (a) Desired and undesired oxidation of “Deoxygenated” macrocycle 2; (b) proposed synthesis of haouamine A (1) in this work from building blocks 4, 5, and 8.

and practical synthetic entry to the indeno-tetrahydropyridine core of haouamine A via amino-alcohol 7.†AA

Results and discussion

As shown in Scheme 3a, the synthesis of haouamine A (1) commenced with the preparation of amino-alcohol 7. Inspired by the protocol originally developed by Wang and co-workers, rhodium-catalyzed diazo-insertion reaction engaging benzocyclobutanol 4 (ref. 8) and diazoester 5 (ref. 9) proceeded smoothly to afford tertiary alcohol 6 in good yield. Notably, this reaction took place with significantly improved yield at room temperature instead of the elevated temperature (100 °C) initially reported by Wang, and was routinely performed on multi-gram scale with further reduced catalyst loading (2 mol% to 0.8 mol%). In preparation for the ensuing intramolecular aziridination (16 to 17), hydroxy methyl ester 6 was elaborated to alkynyl alcohol 15 via oxidative cleavage of diol 12, a two-step deoxygenation of keto ester 13 and reduction of alkynyl methyl ester 14. On treatment with chlorosulfonyl isocyanate, primary alcohol 15 was converted to sulfamate 16 in readiness for the intramolecular aziridination. Analogous to the reaction conditions originally developed by the Du Bois laboratory, rhodium-catalyzed intramolecular aziridination of 16 took place at a slightly elevated temperature (40 °C) to furnish aziridine 17 in high yield as the sole product (e.g. nitrene CH-insertion product(s) was not observed). Sequential reductive transformations on 17 that involved rupture of its aziridine (Pd/C, H2) and cleavage of the sulfamate (AlH3, EtNMe2) yielded amino-alcohol 7 with spectroscopic data in full accordance with literature reports, thereby validated our developed reaction sequence. Furthermore, practicality of the developed sequence has been demonstrated in generating multi-gram quantities (>7 grams. For details, see ESI) of amino-alcohol 7 for the ensuing synthetic investigations.

The synthesis of bicyclic carboxylic acid 8 is outlined in Scheme 3b. Inspired by the recent advances in CH-functionalization of phenylacetic acid derivatives, Pd(OAc)2-catalyzed cross-coupling between quinolinamide 21 (ref. 10) and cyclohexanone 19 (ref. 11) derived vinyl iodide 20 under the aerobic ortho-alkenylation conditions described by Chen and co-workers12 smoothly delivered bicycle 22 as the only detectable product. Hydrolytic amide-bond cleavage through the Boc derivative of quinolinamide 22 completed the synthesis of carboxylic acid 8 together with recovered 8-aminoquinoline directing group.13

Annulation of the tetrahydropyridine domain of haouamine A onto amino-alcohol 7 was realized through an adaptation of the reaction sequence described by Weinreb14 and Wipf groups, through the intermediary primary alcohol 23 and intramolecular aldo-condensation of aldehyde 24, to deliver lactam 25 uneventfully (Scheme 4).14 In preparation for the macrocyclization event and the completion of macrocycle 2/2a, TBS ether 25 was converted to its corresponding tosylate 27 followed by a Ru-catalyzed amide reduction15 to afford amine 9. Intramolecular N-alkylation of amino-tosylate 9 under high-dilution conditions16–18 (where the inclusion of NaI proved crucial) proceeded smoothly to deliver macrocycle 2/2a as a mixture of diastereoisomers (Scheme 4). Notably, diastereoisomeric amino-tosylates [9, d.r. 1 : 1] exhibited different rate of macrocyclization that resulted the formation of diastereoisomerically enriched macrocycle (2 : 2a ~ 2.8 : 1) together with unreacted and diastereoisomERICALLY enriched aminoiodide intermediate (which could be re-subjected to the macrocyclization condition to afford additional supply of macrocycle 2/2a) after 16 hours at 90 °C. On the other hand, inspired by the recently reported palladium-catalyzed intramolecular cross-coupling19 featured in the herquiline syntheses, macrocyclic Suzuki reaction of boronic ester-aryl bromide 29 was also attempted but failed to deliver macrocycle 2/2a (Scheme 5a). Notwithstanding the conformational and mechanistic differences between intramolecular N-alkylation and Suzuki cross-coupling, these results appear to substantiate the importance of site selection for a successful macrocyclization event. This finding is particularly noteworthy and path-pointing for future synthetic investigations in this field since it demonstrated for the first time that by simply replacing a constituent aromatic ring of the haouamine biphenol cyclophane system with a sp3 hybridized “masked” aryl precursor may not guarantee the desired ring closure to take place.

With macrocycle 2/2a in hand, the highly anticipated site-selective oxidation was pursued in earnest (Scheme 4). Having
conducted an exhaustive study of conventional oxidation protocols (osmium-catalyzed dihydroxylation, peracid-mediated epoxidation, hydroboration–oxidation, metal-catalyzed and SeO$_2$-mediated allylic oxidation. For details, see ESI†), and recognizing the possibility to directly access the previously reported enone intermediate $2a$ we opted the SeO$_2$-mediated allylic oxidation as the focal point of our investigations on macrocycle $2a$. After extensive experiments, we discovered that while prolonged treatment with SeO$_2$ at elevated temperature (100 °C) indeed generated analytically detectable amounts of enones $3$ and $3a$, this condition proved highly capricious and difficult to obtain chromatographically pure material. Alternatively, performing the reaction at 45 °C for 5 hours cleanly afforded the allylic alcohol intermediate ($2b$ and $28a$) that could be easily isolated, and subsequent oxidation with PCC smoothly delivered a readily separable mixture of enones $3$ and $3a$. It is worth-noting that allylic oxidation of model substrate $22a$ under the identical reaction condition only proceeded in ~25% conversion (Scheme 5b), suggesting the enhanced reactivity of olefin $2a$ may be a consequence of its strained macrocyclic system. This mechanism-based selection of oxidation/oxygenation protocol proved crucial to achieve the overall selectivity for this challenging late-stage transformation (Scheme 4a). Further conversion of allylic alcohols $28a$ to enones $3/3a$ was ineffective under Dess–Martin periodinane, Swern, and MnO$_2$ oxidation conditions. Enones $3$ and $3a$ exhibited spectroscopic data in complete accordance to those previously reported in the literature, and their conversion to haouamine A and atrop-haouamine A, respectively, have been reported. Finally, optically active alkenyl alcohol $15$ could be conveniently obtained through a resolution process to provide an asymmetric entry to haouamine A (Scheme 5c).

Conclusions

In conclusion, a new synthetic entry to the cyclophane alkaloid natural product haouamine A (1) has been realized. Most notably, a late-stage, site-selective, and strain-accelerated oxidation/oxygenation of macrocycle 2 was successfully implemented to render a novel solution to the biphenoil cyclophane domain of haouamine A. In doing so, a simplified precursor has been identified for the first time to facilitate future chemical investigations of the haouamines by the synthetic community. The construction of the indenotetrahydropyrindine core of haouamine A (1) developed herein also showcased two highly efficient and practical rhodium-
catalyzed carbon–carbon and carbon–nitrogen bond forming processes, namely a diazo-ester (5) insertion to benzocyclobutanol 4 and an intramolecular aziridination of sulfamate 16, respectively. Collectively, the modular synthetic approach developed herein and ample supply of amino-alcohol 7 should enable a ready access to other members of the haouamine family and designed analogues, which is currently under investigation in our laboratory.

Scheme 4 Late-stage oxidation enabled synthesis of haouamine A (1): (a) 3-dimensional rendering and hypothetical transition-state structure to rationalize the highly effective late-stage oxidation/oxygenation of macrocycle 2. Reagents and conditions: (a) EDC·HCl (1.1 equiv.), iPr₂NEt (2.2 equiv.), 8 (1.05 equiv.), CH₂Cl₂, 25 °C, 14 h, 54% for 2 steps from 18; (b) DMP (1.4 equiv.), CH₂Cl₂, 0 to 25 °C, 4 h, 93%; (c) Cs₂CO₃ (4.0 equiv.), CH₃CN/MeOH (10:1), 60 °C, 8 h, 63%; (d) TBAF (1.0 M in THF, 2.0 equiv.), THF, 0 to 25 °C, 14 h, 83%; (e) TsCl (2.0 equiv.), DMAP (0.2 equiv.), Et₃N (5.0 equiv.), CH₂Cl₂, 25 °C, 4 h, 88%; (f) Ru₃(CO)₁₂ (0.1 equiv.), TMDSO (10.0 equiv.), toluene, 60 °C, 5 h, 69%; (g) NaI (10 equiv.), iPr₂NEt (10 equiv.), CH₃CN, 90 °C, 16 h + 16 h, 59% + 27% with one recycling; (h) SeO₂ (1.8 equiv.), NaHCO₃ (5.0 equiv.), 1,4-dioxane, 45 °C, 5 h, 69%; (i) PCC (2.0 equiv.), Celite®, CH₂Cl₂, 25 °C, 4 h, 3a: 58%, 3a: 28%. DMP = Dess–Martin Periodinane; EDC = N-(3-dimethylaminopropyl)-N₀-ethylcarbodiimide; EtOAc = ethyl acetate; PCC = pyridinium chlorochromate; TBAF = tetra-n-butylammonium fluoride; TMDSO = 1,1,3,3-tetramethyldisiloxane.

13 In comparison, Suzuki cross-coupling based synthesis of bicyclic carboxylic acid 8 involved more costly reagents and stringent experimental conditions, particularly in the triflation of ketone 19 and subsequent boronic ester formation. The simplicity of building block 20 and the implementation of aerobic CH-activation based cross-coupling both represented significant improvements compared to the reported total syntheses of haouamines (ref. 3 and 4a–c).

14 Notably, intramolecular aldol condensation of aldehyde 24 under the conditions described by Weinreb and Wipf groups (K2CO3, MeOH, 60 °C, ref. 4d and k) afforded lactam 25 in significantly lower yield.
