Abstract. We study the averaging of fronts moving with positive oscillatory normal velocity, which is periodic in space and stationary ergodic in time. The problem can be formulated as the homogenization of coercive level set Hamilton-Jacobi equations with spatio-temporal oscillations. To overcome the difficulties due to the oscillations in time and the linear growth of the Hamiltonian, we first study the long time averaged behavior of the associated reachable sets using geometric arguments. The results are new for higher than one dimensions even in the space-time periodic setting.

1. Introduction. We investigate the averaging behavior of fronts moving with positive oscillatory normal velocity, which is periodic in space and stationary ergodic in time. The problem can be formulated, using the level-set method, as the homogenization of coercive level set Hamilton-Jacobi equations with spatio-temporal oscillations.

In particular, we study the homogenized (averaging) behavior of the solution $u^\varepsilon = u^\varepsilon(x,t,\omega)$ to the level-set Hamilton-Jacobi equation

$$u^\varepsilon_t + a \left( \frac{x}{\varepsilon}, t, \omega \right) |Du^\varepsilon| = 0 \text{ in } \mathbb{R}^n \times (0, \infty), \quad u^\varepsilon(\cdot,0) = u_0 \text{ on } \mathbb{R}^n,$$

where $u_0 \in UC(\mathbb{R}^n)$, the space of uniformly continuous functions, and, for each element $\omega$ of the underlying probability space $(\Omega, \mathcal{F}, \mathbb{P})$, the velocity $a$ is bounded from above and from below by positive numbers uniformly in $x, t$ and $\omega$, and is periodic in $x$ and stationary ergodic in $t$; more precise assumptions are given in

the next section. The Hamiltonian \( H(x,t,p,\omega) = a(x,t,\omega)|p| \) inherits the above properties in \( x,t \) and, in view of the bounds on \( a \), is coercive and has linear growth in \( p \) uniformly in \( \omega \).

In spite of its simple form and the coercivity of \( H \), the study of the averaging of (1) falls outside of the scope of the existing homogenization theory for Hamilton-Jacobi equations even in the spatio-temporal periodic setting. This is due to the fact that the linear growth and the time oscillations do not yield any uniform in \( \varepsilon \) and \( \omega \) modulus of continuity for the family of functions \( u^\varepsilon \)'s. Having such estimate is essential for the qualitative homogenization theory.

The main result of the paper is:

**Theorem 1.1.** Assume that \( a \) is periodic in \( x \), stationary ergodic in time, strictly positive and bounded. There exists a continuous convex Hamiltonian \( \Pi \) and a set \( \Omega_0 \) of full probability such that, as \( \varepsilon \to 0 \), for all \( \omega \in \Omega_0 \) and locally uniformly in \( \mathbb{R}^n \times [0,\infty) \), \( u^\varepsilon(\cdot,\cdot,\omega) \to \Pi \), the latter being the solution of the Hamilton-Jacobi equation (6).

To explain the obstructions as well as the method we employ to deal with the difficulty outlined earlier, we need to introduce a number of definitions and terminologies.

For \( t > 0 \) and \( \omega \in \Omega \), let \( \mathcal{A}_{0,t}(\omega) \) be the set of solutions (admissible paths) to the controlled system

\[
\begin{aligned}
\gamma'(r) &= f(\gamma(r), r, \xi(r), \omega) := a(\gamma(r), r, \omega)\xi(r, \omega) \text{ a.e. for } r \in (0,t), \\
|\xi(r, \omega)| &\leq 1 \text{ a.e. for } r \in (0,t),
\end{aligned}
\]  

that is

\[
\mathcal{A}_{0,t}(\omega) := \{ \gamma : [0,t] \to \mathbb{R}^n : |\gamma'(r)| \leq a(\gamma(r), r, \omega) \text{ for a.e. } r \in [0,t] \}.
\]

The reachable set \( \mathcal{R}_t(x)(\omega) \) at time \( t > 0 \) emanating from \( x \in \mathbb{R}^n \) at time 0 is

\[
\mathcal{R}_t(x,\omega) := \{ y \in \mathbb{R}^n : \text{there exists } \gamma \in \mathcal{A}_{0,t}(\omega) \text{ such that } \gamma(0) = x, \gamma(t) = y \}.
\]

We are interested in the long time-large space average of \( \mathcal{R}_t(x,\omega) \), that is the limit, as \( t \to \infty \), of

\[
t^{-1}\mathcal{R}_t(x,\omega).
\]

Note that, because the function \( a \) depend on time, the definition of reachable set \( \mathcal{R}_t \) can be made broader so that it depends also on a starting time \( s < t \) and becomes \( \mathcal{R}_t(x,s)(\omega) \). This latter definition is indeed necessary for the analysis and, hence, is done in (18) below. Nevertheless, the result of this paper shows that \( t^{-1}\mathcal{R}_t(x,s)(\omega) \) is independent of the starting time \( s \) and agrees with the limit of (4). Hence, in this introduction, we only consider \( \mathcal{R}_t(x,\omega) \) with starting time fixed at \( s = 0 \).

The study of the asymptotic ergodic behavior of the reachable sets for spatio-temporal periodic \( a \) and \( n = 1 \) goes back to Poincaré and Denjoy; we refer to the book of Arnol’d [9] for details. In this case, for each \( t \geq 0 \), \( \mathcal{R}_t(x) = [\gamma_L(t), \gamma_R(t)] \) with \( \gamma_L, \gamma_R \) prescribed by the dynamical systems

\[
\begin{aligned}
\gamma_R'(t) &= a(\gamma_R(t), t) \text{ for } t > 0 \text{ and } \gamma_R(0) = x, \\
\gamma_L'(t) &= -a(\gamma_L(t), t) \text{ for } t > 0 \text{ and } \gamma_L(0) = x.
\end{aligned}
\]

Then (4) is controlled by the limits, as \( t \to \infty \), of \( t^{-1}\gamma_R(t) \) and \( t^{-1}\gamma_L(t) \), which exist and are the so-called rotation numbers first defined by Poincaré. These results
were generalized, still for \( n = 1 \), for a periodic in \( x \) and stationary ergodic in \( t \) by Li and Lu [27].

To the best of our knowledge, the asymptotic behavior of (4) for \( n \geq 2 \) was unknown, even in the space-time periodic case. As far as we know Theorem 1.1 is the first result for spatial periodic and temporal stationary ergodic a and for all \( n \).

Next we recall the relationship between the reachable sets and the solution of (1) which is based on the control interpretation of (1) and is given by the well known Lax-Oleinik formula. Due to the linear growth of \( H \) with respect to \( |p| \), the Lagrangian \( L(x, t, q, \omega) \), which is the Legendre transform of the map \( p \mapsto H(x, t, p, \omega) \), has the form

\[
L(x, t, q, \omega) = \begin{cases} 0 & \text{if } |q| \leq a(x, t, \omega), \\ +\infty & \text{otherwise.} \end{cases} \tag{5}
\]

Hence the action along a path is finite if and only if this path is admissible, in which case the action is actually zero. As a result, the Lax-Oleinik formula for solutions to (1), for the unit scaling \( \varepsilon = 1 \), yields

\[
u(x, t, \omega) = \inf_{y \in \mathbb{R}^n} \{ u_0(y) : x \in \mathcal{R}_t(y, \omega) \},
\]

and, after a space-time scaling,

\[
u^\varepsilon(x, t, \omega) = \inf_{y \in \mathbb{R}^n} \{ u_0(y) : x / \varepsilon \in \mathcal{R}^\varepsilon_t(y / \varepsilon, \omega) \}.
\]

In this paper, we show that there exists a convex and compact set \( D \subset \mathbb{R}^n \), such that, for every \( t > 0 \), the almost sure long time average \( (\frac{1}{t}) \int_0^t \mathcal{R}^\varepsilon_t \left( \frac{y}{\varepsilon}, \omega \right) \), as \( \varepsilon \to 0 \), is given by \( t^{-1}y + D \). As a result, the set \( \{ y : \frac{x}{\varepsilon} \in \mathcal{R}^\varepsilon_t \left( \frac{y}{\varepsilon}, \omega \right) \} \) converges to the set \( \{ y : x \in y + tD \} \). It then follows that \( u^\varepsilon(x, t, \omega) \) converges almost surely to

\[
\pi(x, t) := \inf_{y \in \mathbb{R}^n} \{ u_0(y) : x \in y + tD \},
\]

which is the solution of the homogenized equation

\[
\pi_t + \mathcal{H}(D \pi) = 0 \text{ in } \mathbb{R}^n \times (0, \infty), \quad \pi(\cdot, 0) = u_0 \text{ on } \mathbb{R}^n \tag{6}
\]

and the effective Hamiltonian \( \mathcal{H} \) is defined through the set \( D \). See Theorem 2.5 and Section 4 below for the details.

The periodic homogenization of coercive Hamilton-Jacobi equations was first studied by Lions, Papanicolaou and Varadhan [28] and, later, Evans [18, 19] and Majda and Souganidis [30]. Ishii established in [24] homogenization in almost periodic settings. The stochastic homogenization of Hamilton-Jacobi equations with convex and coercive Hamiltonians was established independently by Souganidis [37] and Rezakhanlou and Tarver [32]. Lions and Souganidis introduced a general framework to study the homogenization of Hamilton-Jacobi and viscous degenerate Hamilton-Jacobi equations. Uniformly elliptic viscous Hamilton-Jacobi equations were also studied by Kosygina, Rezakhanlou and Varadhan [25], while results with space-time oscillations were obtained for uniformly elliptic viscous Hamilton-Jacobi by Kosygina and Varadhan [26] and superlinear Hamilton-Jacobi equations by Schwab [35]. In [29] Lions and Souganidis gave a simpler proof for homogenization in probability using weak convergence techniques. Their program was extended by Armstrong and Souganidis in [4, 5] who developed a unified approach using the so-called metric problem. The viscous case was later refined by Armstrong and Tran in [6]. All the previously mentioned results in the random setting require that the Hamiltonians are convex. The homogenization or non-homogenization of general
nonconvex Hamiltonians in random environments have attracted much attention recently. A first extension of the homogenization to level-set convex Hamiltonians was proven by Armstrong and Souganidis in [5]. Then, Armstrong, Tran and Yu [7, 8] established stochastic homogenization for separated Hamiltonians of the form \( H = h(p) - V(x, \omega) \) with random potential \( V(x, \omega) \) and general non-convex \( h \) in one dimension. Their methods also established homogenization of some special non-convex Hamiltonians in all dimensions. Gao [21] obtained results for more general non-separated Hamiltonians in one dimension. Armstrong and Cardaliaguet [3] studied the homogenization of positively homogeneous non convex Hamilton-Jacobi equations in strongly mixing environments. More recently, Feldman and Souganidis [20] established homogenization of strictly star-shaped Hamiltonians in similar environments. Ziliotto [39] constructed an example of a non-convex separated Hamiltonian in two dimensions that does not homogenize. Feldman and Souganidis [20] extended the construction to any separated \( H \) that has a strict saddle point. In addition, [20] also yields non-convex Hamiltonians with space-time random potentials for which the Hamilton-Jacobi equation does not homogenize.

Few results are available for non-coercive Hamiltonians and they all rely on some reduction property that compensates for the lack of coercivity; see, for example, Alvarez and Bardi [1], Barles [10] and Imbert and Monneau [23]. A different approach, based on nonresonance conditions, was initiated by Arisawa and Lions [2] and extended to periodic noncoercive-nonconvex Hamiltonians by Cardaliaguet in [12]. Of special interest is the study of noncoercive Hamilton-Jacobi equations associated to moving interfaces. The homogenization of time independent noncoercive level set equations in the periodic setting was established by Cardaliaguet, Lions and Souganidis [13] and recently by Ciomaga, Souganidis and Tran [17] in the random setting. The homogenization of the \( G \)-equation, which is used as models in combustion for front propagating with normal velocity and advection, in periodic environments was established by Cardaliaguet, Nolen and Souganidis [14] (a special case of space periodic incompressible flows was studied by Xin and Yu [38]) and by Cardaliaguet and Souganidis in [16] in random media (a special case was considered by Novikov and Nolen [31]).

We explain now in more detail the nontrivial difficulties encountered in the study of the homogenization of solutions to (1). When \( H \) is coercive, that is \( a \) is strictly positive, and has no time oscillations, then one can easily obtain uniform in \( \varepsilon \) and global in time Lipschitz bounds for \( u^\varepsilon \), which depend only on the Lipschitz constant of \( u_0 \) and the bounds on \( a \). The results of [37] then yield homogenization. If \( H \) grows superlinearly in \( p \) and oscillates in time, Cardaliaguet and Silvestre [15] obtained local uniform space-time \( C^{0,\alpha} \)-estimates, which only depend on the growth condition of the Hamiltonian but not on its smoothness. Then [37] and [35] yield homogenization. Unfortunately no such estimates are known for the problem we study here.

The difficulties associated with the setting we consider here, that is when the Hamiltonian has linear growth with respect to \( |p| \) and time oscillations, can also been seen from the behavior of the minimal time function, that is the smallest time it takes to go from one point to another through admissible paths. As can be seen in [5] and [13], the minimal time function is fundamental for the homogenization theory when the Hamiltonian does not depend on time.
We review next the role of the minimal time function in the study of the long time average of (4) and, hence, the homogenization of (1) in the absence of time oscillations. Throughout this discussion we omit the dependence on $\omega$.

When $a$ and, hence, $f$ in the aforementioned control system are independent of $t$, the reachable set $\mathcal{R}_t(x)$ defined in (3) still makes sense. In fact, in this setting, $\mathcal{R}_t(x)$ does not depend on the starting time $s$ as remarked below (3). Moreover, $\mathcal{R}_t(x)$ can be characterized in terms of the minimal time to reach a point $y \in \mathbb{R}^n$ from a point $x \in \mathbb{R}^n$, which is defined as

$$\theta(y, x) := \inf \{t \geq 0 : y \in \mathcal{R}_t(x)\}.$$  \hfill (7)

Indeed, it is immediate from (3) and (7), that, for all $t > 0$,

$$\mathcal{R}_t(x) = \{y \in \mathbb{R}^n : \theta(y, x) \leq t\}.$$  

A key and very natural property of the minimal time function is subadditivity, that is the fact that, for $x, y, z \in \mathbb{R}^n$,

$$\theta(y, x) \leq \theta(y, z) + \theta(z, x).$$

Moreover, the assume positive lower bound of $a$, yields a universal constant $C > 0$ such that, for all $x, y \in \mathbb{R}^n$,

$$\theta(y, x) \leq C|y - x|.$$  \hfill (8)

It is then possible to apply the subadditive ergodic theorem to obtain the large time average of $\theta$ along any direction. It follows that there exists a 1-positively homogeneous, Lipschitz continuous (with Lipschitz constant $C$ in (8)), convex $\overline{\theta} : \mathbb{R}^n \to \mathbb{R}$ such that, for any $y \in \mathbb{R}^n$ and almost surely in $\omega$,

$$\lim_{t \to \infty} \frac{1}{t} \theta(ty, 0) = \overline{\theta}(y).$$  \hfill (9)

Using the relation between minimal time functions and reachable sets, we deduce further that, for all $x \in \mathbb{R}^n$ and almost surely in $\omega$,

$$\lim_{t \to \infty} \frac{\mathcal{R}_t(x)}{t} = \{y \in \mathbb{R}^n : \overline{\theta}(y) \leq 1\},$$

and, this, eventually determines the homogenization limit of (1) in this setting.

We discuss now what happens when $a$ and, hence, the control system depend on $t$ and, in the same time, we outline the methodology of the paper. In this setting, it is necessary to take into account the starting time in the definition of minimal time function $\theta(x, y)$ in (7) since, for different starting times, the controls for admissible paths are different. We thus need to consider the minimal time function in space-time instead of just space variable. In this framework, the minimal time to reach a point $(y, t) \in \mathbb{R}^n \times [0, \infty)$ from $(x, 0) \in \mathbb{R}^n \times \{0\}$ can be defined as

$$\theta((y, t), (x, 0)) := \begin{cases} t & \text{if } y \in \mathcal{R}_t(x), \\ +\infty & \text{if } y \notin \mathcal{R}_t(x). \end{cases}$$  \hfill (10)

Let $\alpha > 0$ and $\beta > \alpha$ be respectively the lower and upper bounds of $a$. Then, for all $t > 0$,

$$\overline{B}(x, ta) \subset \mathcal{R}_t(x) \subset \overline{B}(x, t\beta),$$

and the space-time reachable set

$$W((x, 0)) := \{(y, t) \in \mathbb{R}^n \times [0, \infty) : \theta((y, t), (x, 0)) < \infty\}$$
emanating from \((x,0)\) satisfies
\[
\bigcup_{t \geq 0} \overline{B}(x,t\alpha) \times \{t\} \subset W((x,0)) \subset \bigcup_{t \geq 0} \overline{B}(x,t\beta) \times \{t\}. \tag{11}
\]

It follows that \(W((x,0))\) has a cone-like shape and is controlled by the two lower and upper cones with speed of propagation \(\alpha\) and \(\beta\) respectively. The problem, however, is that \(\theta(\cdot,(x,0)) = +\infty\) in \(\mathbb{R}^n \times [0,\infty) \setminus W((x,0))\). Hence, it does not seem possible to have any estimates like (8) or to extend the minimal time function to the whole \(\mathbb{R}^n \times [0,\infty)\) as in [17]. Because of this lack of control on the minimal time function, it became necessary to develop the approach described next.

In this paper, we look directly at the spatial reachable sets instead of the space-time minimal time function. As in the discussion above, the definition of reachable sets should depend on a starting time, although we fix it to be zero in the definition (3); see (18) also. Instead of using the joint space-time structure of \(a\), let us consider the enlarged set
\[
R_t(Y) := \bigcup_{x \in Y} R_t(x),
\]
with \(Y := [0,1]^n\); at this point we assume that \(a\) is 1-periodic in space for all \(t\) and \(\omega\). As we show later, this periodicity renders \(R_t(Y)\) to be subadditive, upon slight modification.

It is clear that \(R_t(Y)\) plays the role of a uniform “upper bound” of \(R_t(x)\) for \(x \in Y\), since the spatial periodicity of \(a\) yields, for all \(x \in \mathbb{R}^n\), 
\[
R_t(x) = [x] + R_t(\tilde{x})
\]
where \([x]\) is the integer part of \(x\) and \(\tilde{x} \in Y\).

As it should be expected, \(R_t(Y)\) satisfies some sort of subadditivity property. Indeed, if \(\tilde{Y} := -Y\) is the reflected unit cube, we show in Lemma 3.2 that, for all \(m, k \in \mathbb{N}\) with \(k \leq m\),
\[
R_m(Y) \subset R_k(Y) + R_{m-k}(Y) + \tilde{Y}. \tag{12}
\]

We use then a subadditive ergodic theorem for compact sets due to Schürger [34] and Hansen and Hulse [22], which, however, requires convexity; in fact it is explained in [34] that the claim is, in general, wrong for non convex sets. As a consequence this result can not be applied directly to \(R_t(Y)\)’s, which are not necessarily convex. Instead we we work with the convex hull \(\text{co} R_m(Y)\) of \(R_t(Y)\)’s, which are also subadditive in the sense of (12), and find a compact and convex set \(D \subset \mathbb{R}^n\) such that,
\[
\lim_{m \to \infty} \frac{\text{co} R_m(Y)}{m} = D. \tag{13}
\]

In view of the relation \(R_m(Y) \subset \text{co} R_m(Y)\), \(D\) is only an upper bound for the large time average of \(R_m(Y)\). We show that \(D\) is also a lower bound and, hence, the long time average of \(R_m(Y)\) itself. As mentioned earlier, this is wrong in general, if we do not have any additional properties of the reachable sets.

In turns out that we can use the structure of the the control problem to overcome this difficulty and this is the key observation in our analysis. In Theorem 3.4, we prove that, for any \(y \in D\), there exists a sequence \(\{y_m \in \frac{R_m(Y)}{m} : m \in \mathbb{N}\}\) that stays close to it. This is done by designing paths satisfying the controlled system up to any desired integer time \(m\); the spatial periodicity and temporal stationarity are
cruel in this design. It then follows that $D$ is also a lower bound of the large time average of $\mathcal{R}_t(Y)$ and, hence, it is possible to remove the convex hull in (13). In view of the monotonicity of $\mathcal{R}_t(Y)$ in $t$, $D$ is the large time average of $\mathcal{R}_t(Y)$ along continuous time. Finally, the spatial periodicity also allows us to control $\mathcal{R}_t(x)$ from above by $\mathcal{R}_t(Y)$ and from below by $\mathcal{R}_{t-\ell}(Y)$ for some universal finite constant $\ell$ defined in Lemma 3.3 below. We find then that $D$ is also the large time average of $\mathcal{R}_t(x)$ for all $x \in Y$. The details of these arguments are in the proofs of Theorem 3.4 and Theorem 2.4.

The rest of this paper is organized as follows. In the next section, we specify the general assumptions on the velocity $a(x,t,\omega)$ and state the main theorems of this paper. In Section 3 we establish the large time average $D$ of the enlarged reachable sets. We prove the main theorems of this paper in Section 4, showing that $D$ is also the large time average of the reachable set starting from any point in the unit cube uniformly, and we apply this result to homogenize (1). Finally in Section 5, we study the homogenization of moving fronts where there is an ambient drift in the velocity using the asymptotic behavior of the corresponding reachable set; we also investigate the homogenization of a non-coercive Hamilton-Jacobi equation.

Notations. We work in the $n$-dimensional Euclidean space $\mathbb{R}^n$ and we denote by $\mathbb{Z}^n$ the set of points with integer coordinates. $\mathbb{N}$ denotes the set of natural numbers including zero. Let $Y$ be the unit cell $[0,1]^n$ and and $\hat{Y} := -Y = [-1,0]^n$. For any $x \in \mathbb{R}^n$, we set $(x,\hat{x})$ to be the unique pair in $\mathbb{Z}^n \times [0,1)^n$ such that $x = |x| + \hat{x}$. The open ball in $\mathbb{R}^n$ centered at $x$ with radius $r > 0$ is denoted by $B_r(x)$, and this notation is further simplified to $B_r$ if the center is the origin. The cardinality of a set $K$ that has finite number of elements is denoted by $\text{Card}(K)$. The set of non-empty compact subsets of $\mathbb{R}^n$ is denoted by $\mathcal{C}$. For any $A, B \in \mathcal{C}$ and any $c \in \mathbb{R}$, we set $A + B := \{x + y : x \in A, y \in B\}$ and $c A := \{cx : x \in A\}$. The Hausdorff metric $\rho$ on $\mathcal{C}$ is defined as $\rho(A,B) := \max\{\sup_{x \in A} \inf_{y \in B} |x-y|, \sup_{y \in B} \inf_{x \in A} |x-y|\}$. For any $A \in \mathcal{C}$, $\|A\| := \max\{|x| : x \in A\}$ and $\text{co} A$ and $\mathcal{E}(A)$ are respectively the convex hull and set of extreme points of $A$. The set of non-empty compact and convex subsets of $\mathbb{R}^n$, which is a closed subset of $\mathcal{C}$, is denoted by $\text{co} \mathcal{C}$; $\mathcal{C}^{b,1}(\mathbb{R}^{n+1})$ is the set of bounded, Lipschitz continuous defined on $\mathbb{R}^n$, $\| \cdot \|_\infty$ is the $L^\infty$-norm of a bounded function, and $B(\Xi)$ is the Borel $\sigma$-algebra the metric space $\Xi$.

2. Assumptions, preliminaries and main results.

The setting and assumptions. We consider a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ endowed with an ergodic group of measure preserving transformations $(\tau_k)_{k \in \mathbb{Z}}$, that is, a family of maps $\tau_k : \Omega \to \Omega$ satisfying, for all $k, k' \in \mathbb{Z}$ and all $\mathcal{U} \in \mathcal{F}$,

$$
\tau_{k+k'} = \tau_k \circ \tau_{k'} \quad \text{and} \quad \mathbb{P}[\tau_k \mathcal{U}] = \mathbb{P}[\mathcal{U}]
$$

and

$$
\text{if } \tau_k(\mathcal{U}) = \mathcal{U} \text{ for every } k \in \mathbb{Z}, \text{ then either } \mathbb{P}[\mathcal{U}] = 1 \text{ or } \mathbb{P}[\mathcal{U}] = 0.
$$

As far as $a : \mathbb{R}^n \times \mathbb{R} \times \Omega \to \mathbb{R}$ is concerned, we assume that

(A0) $a$ is measurable with respect to $B(\mathbb{R}^{n+1}) \times \mathcal{F}$,

(A1) $a$ is $\mathbb{Z}^n$-periodic in $x$ and stationary in $t$ with respect to $(\tau_k)_{k \in \mathbb{Z}}$, that is, for every $(x,l) \in \mathbb{R}^n \times \mathbb{Z}^n$, $(t,k) \in \mathbb{R} \times \mathbb{Z}$, and $\omega \in \Omega$,

$$
a(x+l,t,\tau_k\omega) = a(x,t+k,\omega),
$$

2. LARGE TIME AVERAGE OF REACHABLE SETS 921
concerning the reachable sets. For \( t \in \mathbb{R} \), the admissible paths and reachable sets. We recall and define some notions (A2) \( a(\gamma, t, \omega) \) for each \( \omega \) and there exist \( \alpha, \beta > 0 \) such that, for all \( (x, t) \in \mathbb{R}^{n+1} \) and \( \omega \in \Omega \),

\[
\alpha \leq a(x, t, \omega) \leq \beta.
\]

For simplicity, we combine all the assumptions into (A) \( a = a(x, t, \omega) \) satisfies (A0), (A1) and (A2).

**The admissible paths and reachable sets.** We recall and define some notions concerning the reachable sets. For \( t \geq s \) and \( \omega \in \Omega \), the set \( A_{s,t}(\omega) \) of admissible paths is given by

\[
A_{s,t}(\omega) := \{ \gamma : [s, t] \to \mathbb{R}^n : |\gamma'(r)| \leq a(\gamma(r), r, \omega) \text{ for a.e. } r \in [s, t] \}. \tag{15}
\]

The space-time reachable set corresponding to \( (x, s, \omega) \in \mathbb{R}^n \times \mathbb{R} \times \Omega \) is defined by

\[
\Gamma(x, s)(\omega) = \{ (y, t) \in \mathbb{R}^n \times [s, \infty) : \text{there exists } \gamma \in A_{s,t}(\omega) \text{ such that } \gamma(s) = x, \gamma(t) = y \}. \tag{16}
\]

For \( t \geq s \), the (space-time) reachable set from \( (x, s) \) at time \( t \) is

\[
\Gamma_t(x, s)(\omega) := \Gamma(x, s)(\omega) \cap (\mathbb{R}^n \times [s, t]). \tag{17}
\]

The projection of \( \Gamma_t(x, s)(\omega) \) on \( \mathbb{R}^n \) is given by

\[
R_t(x, s)(\omega) := \{ y \in \mathbb{R}^n : \text{there exists } \gamma \in A_{s,t}(\omega) \text{ such that } \gamma(s) = x, \gamma(t) = y \}; \tag{18}
\]

note that, in view of the discussion in the Introduction, \( R_t(x, s)(\omega) \) is the (spatial) reachable set at time \( t \) starting from \( x \) with initial time \( s \).

In our analysis, we use the “enlarged” reachable set

\[
R_t(Y, s)(\omega) := \cup_{x \in Y} R_t(x, s)(\omega),
\]

which is the set of spatial points reachable at \( t \) starting from the unit cell \( Y \) at time \( s \).

Throughout the paper, when the initial time \( s = 0 \), we write

\[
R_t(x)(\omega) := R_t(x, 0)(\omega) \text{ and } R_t(Y)(\omega) := R_t(Y, 0)(\omega).
\]

We discuss next some properties of the reachable sets which we will use in the sequel.

The reachable set \( R_t(x, s) \) for all \( x \in \mathbb{R}^n \), \( s \in \mathbb{R} \) and \( t \geq s \), is compact, and so is the enlarged reachable set \( R_t(Y, s) \); see for instance Cannarsa and Frankowska [11] and the references therein. If the control system (2) is linear, that is if \( f(x, t, \xi) = Mx + L\xi \), then \( R_t(x) \) is convex. In general, when \( f \) is nonlinear in \( x \) and \( \xi \), then \( R_t(x) \) is not convex. Since we do not assume that \( a \) is linear, \( R_t(x) \) is presumably not convex, which makes the study of large time limit of \( R_t(x) \) much more interesting.

The next observation was already discussed in the Introduction.

**Lemma 2.1.** Assume (A). Then, for any \( (x, t, \omega) \in \mathbb{R}^n \times [0, \infty) \times \Omega \),

\[
\mathcal{B}_{t \alpha}(x) \subset R_t(x)(\omega) \subset \mathcal{B}_{t \beta}(x) \tag{19}
\]

and

\[
\mathcal{B}_{t \alpha}(0) \subset R_t(Y)(\omega) \subset \mathcal{B}_{t \beta}(0) + Y. \tag{20}
\]
Proof. If $|y - x| \leq \alpha t$, then the straight line path connecting $y$ to $x$ with speed $\alpha$ is admissible, which implies the first inclusion of (19). On the other hand, for any $\gamma \in A_{0,t}(\omega)$ with $\gamma(0) = x$, $|\gamma(t) - x| \leq \|a\|_{\infty} t \leq \beta t$, which yields the second inclusion of (19).

In view of $R_t(0)(\omega) \subset R_t(Y)(\omega)$, the first inclusion of (20) follows from that of (19). On the other hand, from the definition of $R_t(Y)(\omega)$ and the second inclusion in (19), we have $R_t(Y)(\omega) \subset \bigcup_{x \in Y} \overline{B}_{t \beta}(x) \subset \overline{B}_{t \beta}(0) + Y$. \qed

The second result implies that the reachable sets grow, a fact that follows from their monotonicity in time.

**Lemma 2.2.** Assume (A). Fix $\omega \in \Omega$ and $x \in \mathbb{R}^n$. For any $s \in \mathbb{R}$ and $t_2 \geq t_1 \geq s$,

$$R_{t_1}(x, s)(\omega) \subset R_{t_2}(x, s)(\omega),$$

and, for any $t \in \mathbb{R}$ and $s_1 \leq s_2 \leq t$,

$$R_t(x, s_2)(\omega) \subset R_t(x, s_1)(\omega).$$

These relations are still true for the enlarged reachable sets.

**Proof.** Fix $y \in R_{t_1}(x, s)$, choose $\gamma \in A_{s,t_1}(\omega)$ such that $\gamma(0) = x$ and $\gamma(t_1) = y$, and define $\hat{\gamma}: [0, t_2] \rightarrow \mathbb{R}^n$ by $\hat{\gamma}(r) = \gamma(r)$ for $r \in [0, t_1)$ and $\hat{\gamma}(r) = y$ for $r \in [t_1, t_2]$. It is immediate that $\hat{\gamma} \in A_{s, t_2}(\omega)$ and $\hat{\gamma}(t_2) = y$. This proves (21). The inclusion (22) and the corresponding results for $R_t(Y, s)$ are proved similarly. \qed

**The subadditive ergodic theorem for compact convex sets.** A key tool that we will use is the subadditive ergodic theorem for compact convex sets. We say that a family of $\mathcal{C}$-valued random sets $X = (X_{k,m})(0 \leq k < m)$, where $k, m \in \mathbb{N}$, is stationary if

$$X_{m+1,k+l}(\omega) = X_{m,k}(\tau_l \omega), \quad \text{for all } l, m, k \in \mathbb{N}, \ m \leq k, \ \text{and } \omega \in \Omega,$$

and subadditive if

$$X_{m,k}(\omega) \subset X_{m,l}(\omega) + X_{l,k}(\omega), \quad \text{for all } l, m, k \in \mathbb{N}, \ m < l < k \text{ and } \omega \in \Omega.$$

A more general version of the next result is proved in [34] and [22].

**Theorem 2.3** (Subadditive ergodic theorem). Let $X = (X_{k,m}(\omega))_{0 \leq k < m}$ be a stationary subadditive family of $\mathcal{C}$-valued random sets defined on $(\Omega, \mathcal{F}, \mathbb{P})$ and assume that $\mathbb{E}|X_{0,1}| \leq C$ for some $C > 0$. Then there exists a co-$\mathcal{C}$-valued set $D$ and a subset $\Omega_1 \subset \Omega$ with full measure, such that $n^{-1}X_{0,n}(\omega)$ converges to $D$ in $(\mathcal{C}, \rho)$, as $n \to \infty$, for all $\omega \in \Omega_1$.

**Main theorems.** The first main theorem of this paper concerns the large time average of the reachable sets starting from any point in the unit cell.

**Theorem 2.4.** Assume (A). There exists a compact and convex $D \subset \mathbb{R}^n$ and an event $\overline{\Omega} \in \mathcal{F}$ of full probability such that, for each $\omega \in \overline{\Omega}$ and any $x \in Y$,

$$\lim_{t \to \infty} \frac{R_t(x)(\omega)}{t} = D \quad \text{in} \quad (\mathcal{C}, \rho)$$

and,

$$\lim_{t \to \infty} \sup_{x \in Y} \rho \left( \frac{R_t(x)(\omega)}{t}, D \right) = 0.$$
Next, we identify the effective Hamiltonian from the compact convex set \( D \) of Theorem 2.4 as follows. Let

\[
\mathcal{I}(q) := \begin{cases} 
0 & \text{for } q \in D, \\
+\infty & \text{otherwise},
\end{cases}
\]

and, for \( p \in \mathbb{R}^n \), define

\[
\overline{\mathcal{H}}(p) := \sup_{q \in \mathbb{R}^n} (p \cdot q - \mathcal{I}(q)) = \sup_{q \in D} p \cdot q. 
\tag{25}
\]

It is straightforward that \( \overline{\mathcal{H}} \) is convex and 1-positively homogeneous.

Let \( \overline{\pi} \) be the solution of the following equation

\[
\begin{cases}
\overline{\pi}_t + \overline{\mathcal{H}}(D \overline{\pi}) = 0 & \text{in } \mathbb{R}^n \times (0, \infty), \\
\overline{\pi} = u_0 & \text{on } \mathbb{R}^n \times \{0\}. 
\end{cases} 
\tag{26}
\]

The homogenization result is:

**Theorem 2.5.** Assume (A) and let \( \tilde{\Omega} \) be as defined in Theorem 2.4. Then, for each \( \omega \in \tilde{\Omega} \), the solution \( u^\varepsilon = u^\varepsilon(\cdot, \cdot, \omega) \) of (1) converges locally uniformly in \( \mathbb{R}^n \times [0, \infty) \) to the solution \( \overline{\pi} \) of (26).

3. Large time average of the enlarged reachable sets.

Some properties of the reachable sets and the admissible paths. We investigate, using (A 0), the behavior of the the reachable set \( \mathcal{R}_x(x,t)(\omega) \), when \( x \) and \( t \) are translated, as well as its subadditivity properties.

**Lemma 3.1.** Assume (A). For any \( x \in \mathbb{R}^n \), \( t \geq 0 \), \( k \in \mathbb{N} \) and \( \omega \in \Omega \),

\[
\mathcal{R}_t(x)(\omega) = [x] + \mathcal{R}_t(\hat{x})(\omega)
\tag{27}
\]

and

\[
\mathcal{R}_{k+t}(x,k)(\omega) = \mathcal{R}_t(x)(\tau_k \omega).
\tag{28}
\]

**Proof.** For any \( y \in \mathcal{R}_t(x)(\omega) \), choose \( \gamma \in \mathcal{A}_{0,t}(\omega) \) satisfying \( \gamma(0) = x \) and \( \gamma(t) = y \), and define \( \hat{\gamma} : [0, t] \to \mathbb{R}^n \) by \( \hat{\gamma}(\cdot) = \gamma(\cdot) - [x] \). The periodicity in space of \( a \) yields \( \hat{\gamma} \in \mathcal{A}_{0,t}(\omega) \). Moreover, \( \hat{\gamma}(0) = \hat{x} \), \( \hat{\gamma}(t) = y - [x] \) and, hence, \( y - [x] \in \mathcal{R}_t(\hat{x})(\omega) \) and thus (27) follows. The other direction of inclusion in (27) follows similarly.

To prove (28), for any \( y \in \mathcal{R}_{k+t}(x,k)(\omega) \), choose \( \gamma \in \mathcal{A}_{k,k+t}(\omega) \) such that \( \gamma(k) = x \) and \( \gamma(k+t) = y \) and define \( \hat{\gamma} : [0, t] \to \mathbb{R}^n \) by \( \hat{\gamma}(\cdot) = \gamma(\cdot) + k \). Then, \( \hat{\gamma}(0) = x \) and \( \hat{\gamma}(t) = y \) and, for a.e. \( r \in (0, t) \),

\[
|\hat{\gamma}'(r)| = |\gamma'(k + r)| \leq a(\gamma(k + r), k + r, \omega) = a(\hat{\gamma}(r), r, \tau_k \omega).
\]

It follows that \( \hat{\gamma} \in \mathcal{A}_{0,t}(\tau_k \omega) \), \( y \in \mathcal{R}_t(x)(\tau_k \omega) \), and, hence, \( \mathcal{R}_{k+t}(x,k)(\omega) \subset \mathcal{R}_t(x)(\tau_k \omega) \). The other inclusion follows in the same way. \( \square \)

**Lemma 3.2.** Assume (A). Then, for any \( t \in \mathbb{R} \), \( s \in \mathbb{N} \) such that \( t \geq s \) and \( \omega \in \Omega \),

\[
\mathcal{R}_t(Y)(\omega) \subset \mathcal{R}_s(Y)(\omega) + \mathcal{R}_{t-s}(Y)(\tau_s \omega) + \hat{Y}.
\]
Proof. For \( y \in \mathcal{R}_t(Y)(\omega) \), choose \( \gamma \in \mathcal{A}_{0,t}(\omega) \) such that \( \gamma(0) \in Y \) and \( \gamma(t) = y \). Then, in light of (27) and (28), we get

\[
y = \gamma(t) = \gamma(s) + (\gamma(t) - [\gamma(s)]) + ([\gamma(s)] - \gamma(s)) \
\in \mathcal{R}_s(Y)(\omega) + (\mathcal{R}_t(\gamma(s), s)(\omega) - [\gamma(s)]) + \tilde{Y} \
= \mathcal{R}_s(Y)(\omega) + (\mathcal{R}_{t-s}(\gamma(s))(\tau_s(\omega)) - [\gamma(s)]) + \tilde{Y} \
= \mathcal{R}_s(Y)(\omega) + \mathcal{R}_{t-s}(\gamma(s))(\tau_s(\omega)) + \tilde{Y} \
\subseteq \mathcal{R}_s(Y)(\omega) + \mathcal{R}_{t-s}(Y)(\tau_s(\omega)) + \tilde{Y},
\]

which is the desired conclusion.

Since taking the closed convex hull is a linear operation and \( \tilde{Y} \) is convex and compact, it follows from Lemma 3.2 that

\[
\text{co} \mathcal{R}_m(Y)(\omega) \subseteq \text{co} \mathcal{R}_k(Y)(\omega) + \text{co} \mathcal{R}_{m-k}(Y)(\tau_k(\omega)) + \tilde{Y}.
\] (29)

In the analysis that follows we will need to construct admissible curves connecting any two points within a uniform time. This is the topic of the following lemma.

**Lemma 3.3.** Assume (A) and let \( \ell := \lfloor \sqrt{\alpha}/\alpha \rfloor + 1 \). For each \( \omega \in \Omega \) and any \( y_1, y_2 \in Y \), there exists \( \gamma_{y_1,y_2} \in \mathcal{A}_{0,\ell}(\omega) \) such that \( \gamma_{y_1,y_2}(0) = y_1 \) and \( \gamma_{y_1,y_2}(\ell) = y_2 \).

Proof. If \( y_1 = y_2 \), the path \( \gamma_{y_1,y_2}(\cdot) \equiv y_1 \) yields the desired result. Hence, we assume \( y_1 \neq y_2 \) and note that \( |y_2 - y_1| \leq \sqrt{\alpha} \) and thus \( |y_2 - y_1|/\alpha \leq \ell \). It is immediate that the path satisfies the claim

\[
\gamma_{y_1,y_2}(t) = \begin{cases} 
  y_1 + \frac{t\alpha(y_2 - y_1)}{|y_2 - y_1|}, & t \in [0, |y_2 - y_1|/\alpha], \\
  y_2, & t \in [|y_2 - y_1|/\alpha, \ell],
\end{cases}
\] (30)

satisfies the claim.

\[ \square \]

**The large time average of the enlarged reachable set.** We prove the following theorem which identifies the large time average of the enlarged reachable set.

**Theorem 3.4.** Assume (A). There exist a compact and convex set \( D \subseteq \mathbb{R}^n \) and an event \( \bar{\Omega} \subseteq \mathcal{F} \) of full probability such that, for any \( \omega \in \bar{\Omega} \),

\[
\lim_{t \to \infty} \frac{\mathcal{R}_t(Y)(\omega)}{t} = D \quad \text{in} \quad (\mathcal{C}, \rho).
\] (31)

Following the strategy outlined in the Introduction, we first need identify the long time behavior of the convex hull \( \text{co} \mathcal{R}_m(Y)(\omega) \) of the reachable set \( \mathcal{R}_m(Y)(\omega) \), along integer time \( m \in \mathbb{N} \). To this end, consider the family \( X := (X_{m,k}(\omega))_{0 \leq m < k} \subseteq \text{co} \mathcal{C} \) given by

\[
X_{m,k}(\omega) := \text{co} \mathcal{R}_{k-m}(Y)(\tau_m(\omega)) + \tilde{Y} = \text{co} (\mathcal{R}_{k-m}(Y)(\tau_m(\omega)) + \tilde{Y}).
\] (32)

**Theorem 3.5.** Assume (A). There exist a compact and convex set \( D \subseteq \mathbb{R}^n \) and an event of full probability \( \Omega_0 \subseteq \Omega \) such that, for any \( \omega \in \Omega_0 \),

\[
\lim_{m \to \infty} \frac{X_{0,m}(\omega)}{m} = D \quad \text{in} \quad (\mathcal{C}, \rho),
\] (33)

and

\[
\lim_{m \to \infty} \frac{\text{co} \mathcal{R}_m(Y)(\omega)}{m} = D \quad \text{in} \quad (\mathcal{C}, \rho).
\] (34)
Moreover,
\[ \overline{B}_\alpha \subset D \subset \overline{B}_\beta. \]  
(35)

**Proof.** It is immediate from (32) and (29) that shows that \( X \) is stationary and subadditive. Moreover, in view of Lemma 2.1, \( E\|X_0\| \) is finite. It follows from Theorem 2.3 that there exist a convex set \( D \in \mathcal{C} \) and a set of full probability \( \Omega_0 \subseteq \Omega \) such that, for every \( \omega \in \Omega_0 \), (33) holds. Upon redefining \( \Omega_0 \) as \( \bigcap_{j \in \mathbb{Z}} \tau_j \Omega_0 \), we may assume that \( \Omega_0 \) is invariant under integral translations and has full measure. Note that (33) holds for all \( \omega \in \Omega_0 \).

To prove (34) we fix \( \omega \in \Omega_0 \) and for simplicity, we omit the dependence of \( R_m(Y) \) on it. Since
\[ \rho \left( \frac{\text{co} R_m(Y)}{m}, D \right) \leq \rho \left( \frac{\text{co} R_m(Y)}{m}, \text{co} R_m(Y) + \tilde{Y} \right) + \rho \left( \frac{\text{co} R_m(Y) + \tilde{Y}}{m}, D \right), \]

it is enough to show that the right hand side of the above inequality converges to 0 as \( m \to \infty \). Indeed, in view of (33), the second term on the right hand side above approaches zero as \( m \to \infty \), while, the first term, in light of
\[ \rho(A, A + B) \leq \|B\| \quad \text{for all} \quad A, B \in \mathcal{C}, \]  
(36)

is bounded by \( \|\tilde{Y}/m\| \) and, hence, also converges to zero.

The last claim is immediate from Lemma 2.1 and (33) and (34).

In the following lemma and for future use we show that almost surely the convergence in (34) holds simultaneously for a special family of translations of the realization. The proof is technical, but the benefit of this lemma will be clear later. We recall that \( \ell = \left\lceil \sqrt{n}/\alpha \right\rceil + 1 \).

**Lemma 3.6.** Assume (A). Let \( D \) be as in Theorem 3.5. There exists an event \( \tilde{\Omega} \subset \Omega \) of full probability measure, such that for each \( \omega \in \tilde{\Omega} \) and any integer \( s \geq 0 \),
\[ \lim_{m \to \infty} \frac{\text{co} R_m(Y)(\tau_s(m+\ell)\omega)}{m} = D \quad \text{in} \quad (\mathcal{C}, \rho). \]  
(37)

**Proof.** For each fixed \( s \in \mathbb{N} \), we construct \( \Omega_s \in \mathcal{F} \) with \( \mathbb{P}(\Omega_s) = 1 \) such that (37) holds for \( s \). The conclusion then follows once we define \( \tilde{\Omega} := \bigcap_{s \in \mathbb{N}} \Omega_s \).

For \( s = 0 \), let \( \Omega_0 \) be as defined in Theorem 3.5 and (37) follows. It remains to define \( \Omega_s \) for any fixed \( s \geq 1 \). In view of the pointwise convergence in \( \Omega_0 \) and Egoroff’s theorem, for any \( \delta \in (0, 1) \), there exists \( W_{s,\delta} \subset \Omega_1 \) with \( \mathbb{P}(W_{s,\delta}) > 1 - \frac{\delta}{4\beta} \) and \( M_{s,\delta} \in \mathbb{N} \) such that, if \( m \geq M_{s,\delta} \), then
\[ \sup_{\omega \in W_{s,\delta}} \rho \left( \frac{\text{co} R_m(Y)(\tau_s\omega)}{m}, D \right) < \frac{\delta}{4}. \]

Applying the ergodic theorem to the indicator function \( 1_{W_{s,\delta}} \), we find \( \Omega_{s,\delta} \in \mathcal{F} \) with \( \mathbb{P}(\Omega_{s,\delta}) = 1 \) so that, for each \( \omega \in \Omega_{s,\delta} \),
\[ \lim_{N \to \infty} \frac{1}{N+1} \sum_{k=0}^{N} 1_{W_{s,\delta}}(\tau_k\omega) = \mathbb{P}(W_{s,\delta}) > 1 - \frac{\delta}{4\beta}. \]  
(38)

Let \( \Omega_s := \bigcap_{\delta \in \mathbb{Q} \cap (0, 1)} \Omega_{s,\delta} \). It is clear that \( \Omega_s \in \Omega_1 \) and \( \mathbb{P}(\Omega_s) = 1 \). We need to check that (37) holds for all \( \omega \in \Omega_s \). Fix any such \( \omega \in \Omega_s \) and observe that for...
\( \varepsilon > 0 \), in view of \((38)\), there exists \( N_{s, \varepsilon} > 0 \) so that, for \( N \geq N_{s, \varepsilon} \),
\[
\sum_{k=0}^{N} 1_{W_{s, \varepsilon}}(\tau_k \omega) = \text{Card}\{ k \in [0, N] : k \in \mathbb{N}, \tau_k \omega \in W_{s, \varepsilon} \} > \left( 1 - \frac{\varepsilon}{4s\beta} \right)(N + 1).
\]

Set \( M_{s, \varepsilon} := \max\{ N_{s, \varepsilon}/(2s), 8\sqrt{n}/\varepsilon \} \). Then, for any \( m \geq M_{s, \varepsilon} \), the previous claim with \( N = 2sm \) yields that, inside the set \( N_{s, \varepsilon} \) consists of \( [sm/2s] + 1 \) consecutive integers such that, if \( j \in \mathcal{J} \), then \( \tau_j \omega \) fails to be in \( W_{s, \varepsilon} \).

Consequently, there exists an integer \( \tilde{r} \leq sm \) with \( sm - \tilde{r} \leq \left[ \frac{sm}{2s} \right] \) such that \( \tau_{\tilde{r}} \omega \in W_{s, \varepsilon} \).

Next observe that
\[
\rho \left( \frac{\text{co } \mathcal{R}_m(Y)(\tau_{s(m+\ell)} \omega)}{m}, D \right) \leq \rho \left( \frac{\text{co } \mathcal{R}_m(Y)(\tau_{s(m+\ell)} \omega)}{m}, \frac{\text{co } \mathcal{R}_m(Y)(\tau_{r} \circ \tau_{s} \omega)}{m} \right) + \rho \left( \frac{\text{co } \mathcal{R}_m(Y)(\tau_{r} \circ \tau_{s} \omega)}{m}, D \right).
\]

Since \( \tau_{\tilde{r}} \omega \in W_{s, \varepsilon} \), the second term in the right hand side of the inequality above is bounded from above by \( \varepsilon/4 \). To estimate the first term, we note that \( 0 < s(m + \ell) - \tilde{r} + s\ell \leq \left[ \frac{sm}{2s} \right] \).

In view of Lemma 3.2, we have
\[
\mathcal{R}_m(Y)(\tau_{r} \circ \tau_{s} \omega) \subset \mathcal{R}_{sm-r}(Y)\left( \tau_{r} \circ \tau_{s} \omega \right) + \mathcal{R}_{m-(sm-r)}(Y)\left( \tau_{s(m+\ell)} \omega \right) + \tilde{Y},
\]

where the second line follows from Lemma 2.2.

These relations, together with the fact that \( \mathcal{R}_{sm-r}(Y) \subset \overline{B}_{[\frac{sm}{2s}]\beta} + Y \), imply that
\[
\rho \left( \frac{\text{co } \mathcal{R}_m(Y)(\tau_{s(m+\ell)} \omega)}{m}, \frac{\text{co } \mathcal{R}_m(Y)(\tau_{r} \circ \tau_{s} \omega)}{m} \right) \leq \frac{1}{m} \left( \frac{\varepsilon m}{2} + 2\sqrt{n} \right) \leq \frac{3\varepsilon}{4}.
\]

Combining this with the previous estimate, we showed that \((37)\) holds for the fixed \( s \) and any \( \omega \in \Omega_s \). This verifies the eligibility of \( \Omega_s \) and the proof of the lemma is complete.

It follows from Theorem 3.5 that the average of the convex hull of \( \mathcal{R}_m(Y)(\omega) \) converges to \( D \in \text{co } \mathcal{C} \), which is an upper bound of \( \lim_{m \to \infty} \mathcal{R}_m(Y)(\omega)/m \). To show that they are equal, it remains to prove that
\[
\lim_{m \to \infty} \sup_{x \in D} d(x, \mathcal{R}_m(Y)(\omega)/m) = 0,
\]

and, hence, in view of the the compactness of \( D \), it suffices to show that
\[
\lim_{m \to \infty} d(x, \mathcal{R}_m(Y)(\omega)/m) = 0 \quad \text{for any fixed } x \in D.
\]
This last limit is the key difficulty in the whole proof. As a first step we use the convexity of $D$ and some basic convex analysis to prove the convergence result for any $y \in \mathcal{E}(D)$, the set of extreme points of $D$.

We recall that $e \in D$ is an extreme point of a compact and convex set $D \subset \mathbb{R}^n$ if, whenever $e = \lambda x + (1 - \lambda) y$ with $x, y \in D$ and $\lambda \in [0, 1]$, then either $x = e$ or $y = e$. Moreover $p \in D$ is exposed, if there exists a linear functional $f : \mathbb{R}^d \to \mathbb{R}$ such that $f(p) > f(p')$ for all $p' \in D \setminus \{p\}$.

**Lemma 3.7.** Assume (A) and let $D$ and $\tilde{\Omega}$ be as in Theorem 3.5 and Lemma 3.6 respectively. For each extreme point $y$ of $D$, $\omega \in \tilde{\Omega}$ and $s \in \mathbb{N}$,

$$\lim_{m \to \infty} d\left(y, \frac{R_m(Y)(\tau_{s(m+\ell)}\omega)}{m}\right) = 0. \quad (40)$$

**Proof.** Since, in view of the Straszewicz’s theorem [33, Theorem 18.6], every extreme point of $D$ is the limit of some sequence of exposed points of $D$, without loss of generality, we assume that $y$ is an exposed point of $D$ and choose a linear function $f : \mathbb{R}^n \to \mathbb{R}$ such that $f(y) > f(x)$ for any $x \in D \setminus \{y\}$.

For each $m$, assume that $f$ achieve its maximum in $\text{co} R_m(Y)(\tau_{s(m+\ell)}\omega)$ at $x_m$. Without loss of generality, we may assume that $x_m \in \mathcal{E}(\text{co} R_m(Y)(\tau_{s(m+\ell)}\omega))$. Then in view of (37),

$$\lim_{m \to \infty} f(x_m/m) = f(y).$$

It follows that every cluster point of $x_m/m$, which is in $D$, coincides with $y$. This shows that

$$\lim_{m \to \infty} d\left(y, \mathcal{E}\left(\frac{\text{co} R_m(Y)(\tau_{s(m+\ell)}\omega)}{m}\right)\right) = 0.$$

The desired limit follows from the fact that $\mathcal{E}(\text{co} A) \subset A$ for any compact set $A \subset \mathbb{R}^n$. \qed

With all the previous facts at hand, we may now proceed to the proof of Theorem 3.4. As mentioned earlier, the claim will follow if we show

$$\lim_{k \to \infty} d(x, R_k(Y)(\omega)/k) = 0, \quad \text{for any } x \in D.$$

That is, for any $\varepsilon$ neighborhood $V$ of $x$ and $k$ sufficiently large, we need to find $\gamma \in A_{0,k}(\omega)$ such that $\gamma(k)/k \in V$. Next we explain briefly the idea of how to construct $\gamma$.

We use the Minkowski-Carathéodory theorem [36, Theorem 8.11] to express $x$ as a convex combination of $n + 1$ extreme points $(y_i \in \mathcal{E}(D))_{i=1,\ldots,n+1}$. The reason for this is that, for each extreme point $y_i$, it is possible to find sub-paths $\gamma_{ij} \in A_{0,m}(\tau_{s_{ij}(m+\ell)}\omega)$, for some sequence $(s_{ij})$ and appropriately chosen large $m \in \mathbb{N}$, such that $\gamma_{ij}(m)/m$ lies in a small neighborhood of $y_i$. Then we construct the desired $\gamma \in A_{0,k}(\omega)$ by translating and connecting those sub-paths $(\gamma_{ij})_{ij}$. In the proof that follows, we carefully carry out these arguments. It turns out that, the integer $m$ and the sequence $(s_{ij})$ can be chosen according to some rational approximation of the coefficients in the convex combination of $x$. The periodicity in space and the stationarity in time are crucial for this construction to work. This idea of the construction of admissible paths is illustrated in Fig. 1, where $x$ is assumed to be a convex combination of two extreme points with rational coefficients.
Proof of Theorem 3.4. Since the argument is long, we divide the proof in three steps.

**Step 1. Pointwise convergence in Euclidean distance.** Let \( \tilde{\Omega} \) be as in Lemma 3.6. We show that, for each fixed \( x \in D \) and \( \omega \in \Omega \),

\[
\lim_{k \to \infty} d \left( x, \frac{R_k(Y)(\omega)}{k} \right) = 0. \tag{41}
\]

As explained in the discussion prior to the proof, there exist \( n+1 \) extreme points \( y_1, \ldots, y_{n+1} \) of \( D \) and \( n+1 \) numbers \( \lambda_1, \ldots, \lambda_{n+1} \) in \([0, 1]\) with \( \sum_{i=1}^{n+1} \lambda_i = 1 \) such that

\[
x = \lambda_1 y_1 + \lambda_2 y_2 + \cdots + \lambda_{n+1} y_{n+1}. \tag{42}
\]

It follows from (40) that there exists \( M_\varepsilon \in \mathbb{N} \) such that, if \( m \geq M_\varepsilon \), then

\[
\max_{1 \leq i \leq n+1} \max_{0 \leq s \leq q} d \left( y_i, \frac{R_m(Y)(\tau_{s(m+\ell)}(\omega))}{m} \right) \leq \frac{\varepsilon}{4}. \tag{43}
\]

For any \( k \geq q(M_\varepsilon + \ell) \), let \( m \geq M_\varepsilon \) be the unique integer such that \( q(m+\ell) \leq k < q(m+1+\ell) \) and, for each \( i = 1, 2, \ldots, n+1 \), and \( j = 0, \ldots, r_i - 1 \), set \( s_{ij} := r_i - 1 + j \).

Let \( r_0 := 0 \) so that \( s_{ij} = j \) for \( j = 0, \ldots, r_i - 1 \). Then \( d(y_i, m^{-1}R_m(Y, \tau_{s_{ij}(m+\ell)}(\omega))) \) is controlled by (43), which yields the existence of \( \gamma_{ij} \in A_{0, m}(\tau_{s_{ij}(m+\ell)}(\omega)) \) such that the end point \( y_{ij} := \gamma_{ij}(m) \) satisfies

\[
\left| y_i - \frac{y_{ij}}{m} \right| \leq \frac{\varepsilon}{4}. \tag{44}
\]

We denote the starting point \( \gamma_{ij}(0) \) by \( y_{ij}^0 \), and next we construct an admissible path \( \gamma \in A_{0, k}(\omega) \) using the sub-paths \( \gamma_{ij}, i = 1, 2, \ldots, n+1, j = 0, 1, \ldots, r_i - 1 \), as follows.

Set \( i = 1 \). We connect the sub-paths \( \gamma_{1j} \), with \( j = 0, 1, \ldots, r_1 - 1 \), to construct \( \gamma \in A_{0, r_1(m+\ell)}(\omega) \). For \( 0 \leq t < m \), we set \( \gamma(t) := \gamma_{10}(t) \), and for \( m \leq t < m + \ell \),
we define $\gamma$ to be a bridge connecting $y_{10}$ to $[y_{10}] + y^0_{11}$ constructed as in Lemma 3.3. Note that at $t = m + \ell$, the path is ready to be connected with $\gamma_{11}$. Hence, for $m + \ell \leq t < 2m + \ell$, we define $\gamma(t) = [y_{10}] + \gamma_{11}(t - (m + \ell))$, and then for $2m + \ell \leq t < 2(m + \ell)$ we build a bridge to $[y_{10}] + [y_{11}] + y^0_{12}$. It follows from the periodicity in space and the stationarity in time that $\gamma \in \mathcal{A}_{0,2(m+\ell)}(\omega)$.

We repeat this procedure for a total of $r_1$ times as follows. Suppose $\gamma$ is constructed on $[0, j(m + \ell)]$. Then, for $t \in [j(m + \ell), j(m + \ell) + m]$, set $\gamma(t) := \sum_{l=0}^{r_1-1} [y_{11}j] + \gamma_{1j}(t - j(m + \ell))$. Next, for $t \in [j(m + \ell) + m, (j + 1)(m + \ell)]$, set $\gamma$ to be the bridge that connects $\gamma(j(m + \ell) + m)$ to $\sum_{l=0}^{r_1-1} [y_{11}j] + y^0_{11}$. In the $r_1$-th step and for $r_1(m + \ell) - \ell \leq t \leq r_1(m + \ell)$, $\gamma(t)$ is chosen as a bridge which connects $\gamma(t(m + \ell) - \ell)$ and $\sum_{l=0}^{r_1-1} [y_{11}j] + y^0_{20}$. By construction, $\gamma \in \mathcal{A}_{0,r_1(m+\ell)}(\omega)$ and, in particular, $\gamma(r_1(m + \ell)) = \sum_{j=0}^{r_1-1} [y_{11}j] + y^0_{20}$.

Now suppose that, for some $1 \leq i \leq n$, we have constructed $\gamma \in \mathcal{A}_{0,S_i(m+\ell)}(\omega)$ where $S_i := \sum_{i=1}^{i} r_p$ and, in particular, $\gamma(S_i(m + \ell)) = \sum_{p=1}^{n} \sum_{j=0}^{r_p-1} [y_{pj}] + y^0_{(i+1)0}$. We continue the construction so that $\gamma \in \mathcal{A}_{0,S_{i+1}(m+\ell)}(\omega)$. Since $\gamma(S_i(m + \ell)) = y^0_{(i+1)0}$ modulo an element in $\mathbb{Z}^n$, we can connect the sub-path $\gamma_{i+1}$ to $\gamma$. Then, following the procedure as in the case of $i = 1$, we translate and connect the subpaths $\gamma_{i+1}j$, $j = 0, 1, \ldots, r_{i+1} - 1$, to $\gamma$ and obtain $\gamma \in \mathcal{A}_{0,S_i(m+\ell)}(\omega)$. We have, in particular, $\gamma(S_{i+1}(m + \ell)) = \sum_{p=1}^{n} \sum_{j=0}^{r_p-1} [y_{pj}] + y^0_{(i+2)0}$, which is ready for the next step in the induction.

After $n + 1$ steps, we obtain $\gamma \in \mathcal{A}_{0,q(m+\ell)}$. We can set $y^0_{(n+2)0} := 0$ in the $(n+1)$-th step, so that $\gamma(q(m + \ell)) = \sum_{i=1}^{n+1} \sum_{j=0}^{r_i-1} [y_{ij}]$.

Finally, for $q(m + \ell) \leq t < k$, we let $\gamma(t) = \gamma(q(m + \ell))$. Then, $\gamma \in \mathcal{A}_{0,k}(\omega)$, and

$$\gamma(k) = \sum_{i=1}^{n+1} \sum_{j=0}^{r_i-1} y_{ij} \in \mathcal{R}_k(Y)(\omega) \frac{1}{k}.$$ 

Let $K_{\varepsilon} := \max \{ q(M_x + \ell), [8q(\ell + 1)\beta/\varepsilon] + 1 \}$ and observe that, if $k \geq K_{\varepsilon}$, then $|x_k - x| < \varepsilon$. Indeed, from the construction above, we have

$$|x - x_k| \leq \sum_{i=1}^{n+1} \left( \lambda_i - \frac{r_i}{q} \right) y_i + \sum_{i=1}^{n+1} \frac{r_i}{q} y_i - \sum_{i=1}^{n+1} \sum_{j=0}^{r_i-1} \frac{[y_{ij}]}{k}.$$ 

For the first term on the right hand side above, in view of (35) and $y_i \in D \subset \mathbb{B}_\beta(0)$, we have

$$\sum_{i=1}^{n+1} \left( \lambda_i - \frac{r_i}{q} \right) y_i \leq \beta \sum_{i=1}^{n+1} \frac{\varepsilon}{4(n+1)} \varepsilon = \varepsilon.$$ 

For the second term, we rewrite the sum as

$$\sum_{i=1}^{n+1} \sum_{j=0}^{r_i-1} \left( \frac{y_i}{q} - \frac{y_{ij}}{k} \right) = \sum_{i=1}^{n+1} \sum_{j=0}^{r_i-1} \left( \frac{m}{k} \left( y_i - y_{ij} \right) + \frac{1}{q} - \frac{m}{k} \right) y_i + \frac{y_{ij}}{k}.$$ 

and estimate each of the three terms in the sum below.

Using that $qm < k$, we find

$$\sum_{i=1}^{n+1} \sum_{j=0}^{r_i-1} \frac{m}{k} \left| y_i - y_{ij} \right| \leq \frac{\varepsilon q m}{4} \frac{\varepsilon q m}{4} < \frac{\varepsilon}{4},$$
the fact that \( y_j \in D \subset B_\beta \) yields
\[
\sum_{i=1}^{n+1} \sum_{j=1}^{r_i} \left( \frac{1}{q} - \frac{m}{k} \right) y_i \leq \beta \sum_{i=1}^{n+1} \sum_{j=1}^{r_i} \left( \frac{1}{q} - \frac{m}{k} \right) = \beta \left( 1 - \frac{qm}{k} \right) \leq \frac{\beta(q+1)}{k} \leq \frac{\varepsilon}{8},
\]
and, finally and for the third term, since \( \hat{y}_{ij} \in Y \subset B_{\sqrt{n}} \) we have
\[
\sum_{i=1}^{n+1} \sum_{j=1}^{r_i} \frac{\hat{y}_{ij}}{k} \leq \frac{q\sqrt{n}}{k} \leq \frac{\beta(q+1)}{k} \leq \frac{\varepsilon}{8}.
\]
Combining these estimates above, we establish (41).

**Step 2. Convergence in Hausdorff metric.** Since we work with a fixed \( \omega \in \Omega \), for simplicity, we omit its dependence.

We prove that \( D \) is the long time average of \( R_m(Y)/m, m \in \mathbb{N} \), that is
\[
\lim_{m \to \infty} \frac{R_m(Y)}{m} = D \quad \text{in } (\mathcal{E}, \rho). \tag{44}
\]
Let \( f_m : D \to \mathbb{R} \) be defined by
\[
f_m(x) := d \left( x, \frac{R_m(Y)}{m} \right) = \inf_{y \in R_m(Y)/m} d(x, y).
\]
In view of (41), \( f_m(x) \to 0 \) for each \( x \in D \). Since the sequence \( (f_m)_{m \in \mathbb{N}} \) is uniformly bounded and equicontinuous in \( D \), it follows that actually \( f_m \to 0 \) uniformly in \( D \), that is
\[
\lim_{m \to \infty} \sup_{x \in D} \inf_{y \in \mathcal{R}_m(Y)/m} d(x, y) = 0. \tag{45}
\]
Next we use (34) and the fact that \( \mathcal{R}_m(Y) \subset \text{co} \mathcal{R}_m(Y) \) for all \( m \in \mathbb{N} \) to get
\[
0 \leq \limsup_{m \to \infty} \sup_{x \in \mathcal{R}_m(Y)/m} \inf_{y \in D} d(x, y) \leq \limsup_{m \to \infty} \sup_{x \in \text{co} \mathcal{R}_m(Y)/m} \inf_{y \in D} d(x, y) = 0,
\]
(46)
Finally, (45) and (46) together confirm the claim (44).

**Step 3. From discrete to continuous time.** We prove that \( D \) is the long time limit of \( \mathcal{R}_t(Y)/t \) for \( t \in \mathbb{R} \).

Recall that, for any \( A \in \mathcal{E} \) and \( c \in \mathbb{R} \),
\[
\rho(cA, A) \leq |c-1||A| \tag{47}
\]
This follows from the observation that, for any \( x \in cA \), there exists \( x' \in A \) such that \( x = cx' \) and, since \( |x - x'| = |cx - x'| \leq |c-1||A| \),
\[
\sup_{x \in cA} \inf_{y \in A} |x-y| \leq |c-1||A|,
\]
while, for any \( x \in A \), there exists \( x' \in cA \) such that \( x' = cx \) and, since \( |x - x'| = |cx - x| \leq |c-1||A| \),
\[
\sup_{x \in A} \inf_{y \in cA} |x-y| \leq |c-1||A|.
\]
Also the monotonicity of \( \mathcal{R}_t(Y) \) with \( t > 0 \) yields
\[
\mathcal{R}_{[t]}(Y) \subset \mathcal{R}_t(Y) \subset \mathcal{R}_{[t]+1}(Y).
\]
It follows that
\[
\sup_{x \in \mathcal{R}_t(Y)} \inf_{y \in D} |x-y| \leq \sup_{x \in \mathcal{R}_{[t]+1}(Y)} \inf_{y \in D} |x-y| \leq \rho(\mathcal{R}_{[t]+1}(Y), tD),
\]
and,
\[ \sup_{x \in D} \inf_{y \in R(Y)} |x - y| \leq \sup_{x \in D} \inf_{y \in R(Y)} |x - y| \leq \rho(R_{i\ell}(Y), tD) \]
and, thus,
\[ \rho(R_i(Y), tD) \leq \max \{ \rho(R_{i\ell}(Y), tD), \rho(R_{i\ell+1}(Y), tD) \} . \quad (48) \]

Using the triangle inequality and (47), we also get
\[ \rho(R_{i\ell}(Y), tD) \leq \rho(R_{i\ell}(Y), [t]D) + \rho([t]D, tD) \leq \rho(R_{i\ell}(Y), [t]D) + \|D\|, \quad (49) \]
and, as above,
\[ \rho(R_{i\ell+1}(Y), tD) \leq \rho(R_{i\ell+1}(Y), ([t] + 1)D) + \|D\|. \quad (50) \]

Finally, in view of the positive homogeneity of \( \rho \) and (48), (49), and (50), we have
\[ \rho \left( \frac{R_i(Y)}{t}, D \right) \leq \max \left\{ \left[ \frac{t}{t} \rho \left( \frac{R_{i\ell}(Y)}{[t]}, D \right) \right], \left[ \frac{t}{t} + 1 \right] \rho \left( \frac{R_{i\ell+1}(Y)}{[t] + 1}, D \right) \right\} + \frac{\|D\|}{t} \rightarrow 0. \]
This completes the proof of the theorem. \( \Box \)

In this somewhat more standard setting, \( a(x, t) \) is \( \mathbb{Z}^{n+1} \)-periodic, that is, for \( (x, t) \in \mathbb{R}^n \times \mathbb{R} \), and \( (k, l) \in \mathbb{Z}^n \times \mathbb{Z} \),
\[ a(x + k, t + l) = a(x, t), \]
the proof simplifies considerably. Indeed this is a special case of the general setting of Section 2 and corresponds to \( \Omega \) having one single element. It is then easy to see that, for any \( x \in \mathbb{R}^n \), \( k \in \mathbb{N} \) and \( t \geq 0 \), \( R_i(x) = [x] + R_i(\hat{x}) \) and \( R_{i+k}(x, k) = R_i(x) \).
Moreover, as in Lemma 3.2, the family \( \{ R_m(Y) \}_{m \in \mathbb{N}} \) is almost subadditive, in the sense that, for all \( m, k \in \mathbb{N} \) with \( k < m \),
\[ R_m(Y) \subset R_k(Y) + R_{m-k}(Y) + \hat{Y}. \quad (51) \]

It follows that \( \lim_{m \to \infty} co R_m(Y)/m = D \) in \( (\mathcal{E}, \rho) \). As before, we can prove that \( D \) is also the limit of \( R_m(Y)/m \), once we establish (41). The proof of the latter is much simpler in the space-time periodic setting. We do not need the technical Lemma 3.6 which, in fact, is no different than Theorem 3.5. Indeed, for any \( x \in D \) which is a convex combination of \( (y_i \in \mathcal{E}(D))_{i=1,\ldots,n+1} \), to construct \( \gamma \in \mathcal{A}_{0,k} \) as in the proof of Theorem 3.4 above, we only use one sub-path \( \gamma_i \in \mathcal{A}_{0,m} \) for each \( y_i \), and then copy, translate and connect them. In the temporal random setting, the environment does not simply repeat itself and, for each \( y_i \), we had to find a sequence of sub-paths \( (\gamma_{ij} \in \mathcal{A}_{0,m} \tau_{s_{ij}(m+\ell)} \omega)_{0 \leq j \leq r_i, -1} \), where \( \tau_{s_{ij}(m+\ell)} \omega \) takes care of the change of the environment.

4. The proofs of the main results. We prove Theorem 2.4 first and demonstrate how the large time average of the enlarged reachable set \( R_i(Y)(\omega) \) controls that of reachable set \( R_i(x)(\omega) \) from any point. Then we apply Theorem 2.4 to prove the homogenization theory for the level-set equation (1).
Large time average of reachable set from a point. Theorem 2.4 says, essentially, that the large time average of the reachable set $\mathcal{R}_t(x)(\omega)$ converges in $(\mathcal{C},\rho)$ uniformly in $Y$. In view of (27), this convergence is in fact local uniform in $\mathbb{R}^n$.

Proof of Theorem 2.4. Set $\bar{\Omega}$ be as in Lemma 3.6 and $\ell = [\sqrt{n/\alpha}] + 1$ as in Lemma 3.3. For any $\omega \in \bar{\Omega}$ and any $x \in Y$, in view of (19), we have $Y \subset B_{\sqrt{n}}(x) \subset \mathcal{R}_t(x)(\omega)$. Moreover, the definition of $\mathcal{R}_t$ and (28), for $t > \ell$, yield

$$\mathcal{R}_t(x)(\omega) = \bigcup_{y \in \mathcal{R}_t(x)(\omega)} \mathcal{R}_t(y, \ell)(\omega) = \bigcup_{y \in \mathcal{R}_t(x)(\omega)} \mathcal{R}_{t-\ell}(y)(\tau_\ell \omega) \supset \bigcup_{y \in Y} \mathcal{R}_{t-\ell}(y)(\tau_\ell \omega) = \mathcal{R}_{t-\ell}(Y)(\tau_\ell \omega),$$

and, thus,

$$\mathcal{R}_{t-\ell}(Y)(\tau_\ell \omega) \subset \mathcal{R}_t(x)(\omega) \subset \mathcal{R}_t(Y)(\omega). \tag{52}$$

Using an argument similar to the one that leads to (48), we obtain

$$\rho(\mathcal{R}_t(x)(\omega), tD) \leq \max \left\{ \rho(\mathcal{R}_{t-\ell}(Y)(\tau_\ell \omega), tD), \rho(\mathcal{R}_t(Y)(\omega), tD) \right\}. \tag{53}$$

Note that estimate above holds for all $x \in Y$, while the right hand side is independent of $x$. As a result, (53) can be improved to

$$\sup_{x \in Y} \rho \left( \frac{\mathcal{R}_t(x)(\omega)}{t}, D \right) \leq \max \left\{ \rho \left( \frac{\mathcal{R}_{t-\ell}(Y)(\tau_\ell \omega)}{t}, D \right), \rho \left( \frac{\mathcal{R}_t(Y)(\omega)}{t}, D \right) \right\}, \tag{54}$$

and to conclude we only need to control each of the two terms inside the max on the right hand side.

Theorem 3.4 yields that the second term converges to zero as $t \to \infty$, while for the the first term, using (47) and the positive homogeneity of $\rho$, we get

$$\rho \left( \frac{\mathcal{R}_{t-\ell}(Y)(\tau_\ell \omega)}{t}, D \right) \leq \rho \left( \frac{\mathcal{R}_{t-\ell}(Y)(\tau_\ell \omega)}{t}, \frac{t-\ell}{t} D \right) + \rho \left( \frac{t-\ell}{t} D, D \right) \tag{55}$$

$$\leq \frac{t-\ell}{t} \rho \left( \frac{\mathcal{R}_{t-\ell}(Y)(\tau_\ell \omega)}{t}, D \right) + \frac{\|D\|}{t}.$$ 

As $t \to \infty$, the last term above vanishes. The proof of (24) is now complete, and since (23) is a weaker statement, it follows immediately.

The homogenization of the level-set PDE. Recall that the Lax-Oleinik formula for the solution of (26) yields that

$$\pi(x,t) = \inf \{ u_0(y) : \frac{x-y}{t} \in D \} = \inf \{ u_0(y) : x \in y + tD \}.$$ 

Proof of Theorem 2.5. Fix $\omega \in \bar{\Omega}$, $T > 0$ and $R > 0$. The representation formula of $u^\varepsilon$ gives, for any $(x,t) \in B_R \times [0,T]$,

$$u^\varepsilon(x,t,\omega) = \inf \left\{ u_0(y) : \frac{x-y}{\varepsilon} \in \mathcal{R}_{\frac{T}{\varepsilon}} \left( \frac{y}{\varepsilon} \right)(\omega) \right\}$$

$$= \inf \left\{ u_0(y) : x \in \varepsilon \left( \left[ \frac{y}{\varepsilon} \right] + \mathcal{R}_{\frac{T}{\varepsilon}} \left( \frac{y}{\varepsilon} - \left[ \frac{y}{\varepsilon} \right] \right)(\omega) \right) \right\}. \tag{56}$$

In light of (19), for $\varepsilon \in (0,1)$ and $t \in [0,T]$,

$$D_\varepsilon(y,t,\omega) := \varepsilon \left( \left[ \frac{y}{\varepsilon} \right] + \mathcal{R}_{\frac{T}{\varepsilon}} \left( \frac{y}{\varepsilon} - \left[ \frac{y}{\varepsilon} \right] \right)(\omega) \right)$$

$$= y + \varepsilon \left[ \mathcal{R}_{\frac{T}{\varepsilon}} \left( \frac{y}{\varepsilon} - \left[ \frac{y}{\varepsilon} \right] \right)(\omega) - \left( \frac{y}{\varepsilon} - \left[ \frac{y}{\varepsilon} \right] \right) \right]$$

$$\subset y + \varepsilon B_{\frac{T}{\varepsilon} \beta} \subset y + B_{T\beta}, \tag{57}$$
a fact yielding that \( x \in D_\varepsilon(y, t, \omega) \) only if \( |y| \leq T\beta + R \).

Next let \( K_\varepsilon(x, t, \omega) := \{ y : x \in D_\varepsilon(y, t, \omega) \} \) and \( K(x, t) := \{ y : x \in y + tD \} \).

Then \( K(x, t) = x - tD \) and we show that
\[
\lim_{\varepsilon \to 0} \sup_{(x, t) \in B_R \times [0, \delta]} \rho(K_\varepsilon(x, t, \omega), K(x, t)) = 0. \tag{58}
\]

Once this limit is established, it follows that
\[
u^\varepsilon(x, t, \omega) = \inf \{ u_0(y) : x \in D_\varepsilon(y, t, \omega) \} = \inf \{ u_0(y) : y \in B_{T\beta + R} \text{ and } y \in K_\varepsilon(x, t, \omega) \} \xrightarrow{\varepsilon \to 0} \inf \{ u_0(y) : y \in B_{T\beta + R} \text{ and } y \in K(x, t) \} = \inf \{ u_0(y) : x \in y + tD \} = u(x, t),
\]
and, moreover, the convergence is uniform on \( B_R \times [0, \delta] \).

It remains to prove (58). Fix \( \delta > 0 \) and consider first the case \( 0 \leq t \leq \delta \). In view of (57), for all \( x \in B_R \),
\[
\{ x \} \subset K_\varepsilon(x, t, \omega) \subset \{ y : x \in y + B_{1\beta} \} = x - B_{1\beta},
\]
and it follows that
\[
\sup_{y_1 \in K_\varepsilon(x, t, \omega)} \inf_{y_2 \in K(x, t)} |y_1 - y_2| \leq \rho(x - B_{1\beta}, x - tD) = t\rho(B_{\beta}, D) \leq \delta \rho(B_{\beta}, D),
\]
and
\[
\sup_{y_1 \in K(x, t)} \inf_{y_2 \in K_\varepsilon(x, t, \omega)} |y_1 - y_2| \leq \rho(x - tD, \{ x \}) = t\|D\| \leq \delta \|D\|. \tag{59}
\]

Let \( C := \max(\rho(B_{\beta}, D), \|D\|) \). Since the two estimates above are uniform in \( x \) and \( t \), we get
\[
\sup_{(x, t) \in B_R \times [0, \delta]} \rho(K_\varepsilon(x, t, \omega), K(x, t)) \leq C\delta. \tag{59}
\]

Next we consider the case \( t > \delta \). Taking \( \varepsilon \) small so that \( t/\varepsilon > \ell \), we claim that, for all \( x \in B_R \),
\[
x - \varepsilon R_{\frac{1}{\ell}}(Y)(\tau_{1\omega}) \subset K_\varepsilon(x, t, \omega) \subset x - \varepsilon R_{\frac{1}{\ell}}(Y)(\omega) + \varepsilon Y. \tag{60}
\]

The first inclusion follows from the observation that, if \( x \in y + \varepsilon R_{\frac{1}{\ell}}(Y)(\tau_{1\omega}) \), then
\[
x \in y + \varepsilon \left[ R_{\frac{1}{\ell}} \left( \frac{y}{\varepsilon} - \left[ \frac{y}{\varepsilon} \right] \right) (\omega) - \left( \frac{y}{\varepsilon} - \left[ \frac{y}{\varepsilon} \right] \right) \right] = D_\varepsilon(y, t, \omega),
\]
which is a consequence of the first inclusion in (52).

The second inclusion in (60) is due to the fact that, if \( x \in D_\varepsilon(y, t, \omega) \), then
\[
x \in y + \varepsilon R_{\frac{1}{\ell}}(Y)(\omega) + \varepsilon Y,
\]
which follows from the second inclusion in (52). Thus,
\[
\sup_{y_1 \in K_\varepsilon(x, t, \omega)} \inf_{y_2 \in K(x, t)} |y_1 - y_2| \leq \rho \left( x - \varepsilon R_{\frac{1}{\ell}}(Y)(\omega) + \varepsilon Y, x - tD \right)
\]
\[
= t\rho \left( \frac{R_{\frac{1}{\ell}}(Y)(\omega)}{t/\varepsilon} + \frac{\varepsilon Y}{t}, D \right),
\]
and
and
\[
\sup_{y_1 \in K(x,t)} \inf_{y_2 \in K_x(x,t,\omega)} |y_1 - y_2| \leq \rho \left( x - tD, x - \varepsilon R_{t/\varepsilon}^\delta(Y) (\tau_\omega) \right) = t\rho \left( D, \frac{R_{t/\varepsilon}^\delta(Y) (\tau_\omega)}{t/\varepsilon} \right).
\]

Again the uniformity in \(x\) and \(t\) of the last two estimates are uniform in \(x\) and \(t\) implies
\[
\sup_{(x,t) \in B_R \times (0,T)} \rho(K_\varepsilon(x,t,\omega), K(x,t)) \leq T \max \left\{ \rho \left( \frac{R_{t/\varepsilon}^\delta(Y) (\omega)}{t/\varepsilon}, D \right), \rho \left( \frac{R_{t/\varepsilon}^\delta(Y) (\tau_\omega)}{t/\varepsilon}, D \right) \right\} + \varepsilon \|\dot{Y}\|. \tag{61}
\]

We first let \(\varepsilon \to 0\) and apply Theorem 3.4 in (61) and then we let \(\delta \to 0\) in (59). Combining these two estimates, we establish (58) and complete the proof of the theorem. \(\square\)

5. Further applications. In this section, we present a couple of more examples of Hamilton-Jacobi equations with Hamiltonians of linear growth. The first concerns front propagation in an environment that is subjected to a background drift, and the second involves a non-coercive Hamiltonian.

Front propagation with ambient drift. We study the behavior, as \(\varepsilon \to 0\), of the solution \(u^\varepsilon = u^\varepsilon(x,t,\omega)\) to
\[
\begin{cases}
\displaystyle u^\varepsilon_t + a \left( \frac{x}{\varepsilon}, \frac{t}{\varepsilon}, \omega \right) |Du^\varepsilon| + b \left( \frac{x}{\varepsilon}, \frac{t}{\varepsilon}, \omega \right) \cdot Du^\varepsilon = 0 & \text{in } \mathbb{R}^n \times (0,\infty), \\
u^\varepsilon = u_0 & \text{on } \mathbb{R}^n \times \{0\},
\end{cases} \tag{62}
\]
which models front propagation with velocity \(V = a \left( \frac{x}{\varepsilon}, \frac{t}{\varepsilon}, \omega \right) \nu + b \left( \frac{x}{\varepsilon}, \frac{t}{\varepsilon}, \omega \right)\), where \(\nu\) is the normal vector to the front.

In addition to (A), we assume that the random process \(b(\cdot,\cdot,\omega) \in C^{0,1}(\mathbb{R}^{n+1}, \mathbb{R}^n)\) satisfies
\[(B1) \ b = b(x,t,\omega) \text{ is } \mathbb{Z}^n\text{-periodic in } x \text{ and stationary in } t \text{ with respect to } (\tau_k)_{k \in \mathbb{Z}},
\]
that is, for every \((x,l) \in \mathbb{R}^n \times \mathbb{Z}^n\), \((t,k) \in \mathbb{R} \times \mathbb{Z}\), and \(\omega \in \Omega\),
\[
b(x + l, t, \tau_k \omega) = b(x, t + k, \omega),
\]
\[(B2) \ \text{there exist } \eta > 0 \text{ such that for all } (x,t) \in \mathbb{R}^{n+1} \text{ and } \omega \in \Omega,
\]
\[
\alpha - |b(x,t,\omega)| \geq \eta. \tag{63}
\]

As before, we group the above assumptions as
\[(B) \ b = b(x,t,\omega) \text{ satisfies (B1) and (B2)}.
\]

In view of (B2), the Hamiltonian \(H(x,t,p,\omega) = a(x,t,\omega)|p| + b(x,t,\omega) \cdot p\) is coercive and the representation formula for the solution \(u^\varepsilon\) is
\[
u^\varepsilon(x,t,\omega) = \inf \left\{ u_0(y) : \frac{x}{\varepsilon} \in \mathcal{R}^\frac{1}{\varepsilon} \left( \frac{y}{\varepsilon} \right) (\omega) \right\}, \tag{64}
\]
for the reachable set \(\mathcal{R}^\varepsilon(x)(\omega)\) with admissible paths associated to the control system
\[
\begin{cases}
\gamma'(r) = f(\gamma(r), r, \xi(r)) := b(\gamma(r), r) + a(\gamma(r), r) \xi(r) & \text{for } r \in (0,t), \\
|\xi(r)| \leq 1 & \text{a.e. } r \in (0,t),
\end{cases}
\]
The set of admissible paths in the time interval $[s, t]$ is

$$
\mathcal{A}_{s,t}(\omega) := \{ \gamma : [s, t] \to \mathbb{R}^n : |\gamma'(r) - b(\gamma(r), r, \omega)| \leq a(\gamma(r), r, \omega) \}
$$

for a.e. $r \in [s, t]$. (65)

Following the arguments developed earlier, we can show that the large time average $R_t(x)(\omega)/t$, for almost all $\omega \in \Omega$, converges in $(\mathbb{C}, \rho)$, to some compact and convex subset $D$ of $\mathbb{R}^n$. Indeed, thanks to (B2), $\overline{B}_{t\eta}(x) \subset R_t(x)(\omega) \subset \overline{B}_{t(\beta' + \alpha - \eta)}(x)$ (this is the analogue of (19)) and, furthermore, any two points $y_1, y_2 \in Y$ can be connected by an admissible path within time $t' := [\sqrt{n}/\eta] + 1$ (this is an analogue of Lemma 3.3). On the other hand, due to the periodicity in space and stationary ergodicity in time of the control system, the translation rules and the (modified) subadditivity of $R_t(x)(\omega)$, that is Lemma 3.1 and Lemma 3.2, still hold. Hence, we can carry out the whole program of the analysis in this paper and obtain the following homogenization result. Its proof is exactly the same as those of Theorem 2.4 and Theorem 2.5 and hence is omitted.

**Theorem 5.1.** Assume (A) and (B). There exists a compact and convex $D \subset \mathbb{R}^n$ and an event $\tilde{\Omega} \subset \mathcal{F}$ of full probability such that, for each $\omega \in \tilde{\Omega}$:

(i) The large time average of reachable set converges locally uniformly in $D$, that is, as $t \to \infty$,

$$
\lim_{t \to \infty} \sup_{x \in Y} \rho \left( \frac{R_t(x)(\omega)}{t}, D \right) = 0.
$$

(ii) As $\varepsilon \to 0$, the solution $v^\varepsilon = v^\varepsilon(\cdot, \cdot, \omega)$ of (62) converges locally uniformly in $\mathbb{R}^n \times [0, \infty)$ to $v^\varepsilon$ the solution to (26) with $\mathcal{H}$ defined as in (25).

**A non-coercive Hamilton-Jacobi equation.** We are interested in the limit, as $\varepsilon \to 0$, of the solution $v^\varepsilon = v^\varepsilon(x', t, \omega)$ of

$$
\begin{cases}
  v^\varepsilon_t + a \left( \frac{x'}{\varepsilon} \right) \left| D_x v^\varepsilon \right| + v^\varepsilon_{x_n+1} = 0 & \text{in } \mathbb{R}^{n+1} \times (0, \infty) \\
  v^\varepsilon = v_0 & \text{on } \mathbb{R}^{n+1} \times \{0\}.
\end{cases}
$$

(67)

Here $x' = (x, x_{n+1}) \in \mathbb{R}^n \times \mathbb{R}$ and $a \in C^{0,1}(\mathbb{R}^{n+1})$ satisfies (A), with $x_{n+1}$ playing the role of $t$. We also write $p', q', y' \in \mathbb{R}^{n+1}$ as $p' = (p, p_{n+1}), q' = (q, q_{n+1}), y' = (y, y_{n+1}) \in \mathbb{R}^n \times \mathbb{R}$.

For $(p', q') \in \mathbb{R}^{n+1} \times \mathbb{R}^{n+1}$, the Hamiltonian is

$$
H'(y', p') = a(y')|p| + p_{n+1},
$$

and, for $(q', y') \in \mathbb{R}^{n+1} \times \mathbb{R}^{n+1}$, the Lagrangian is

$$
L'(y', q') = \begin{cases}
  0, & \text{for } q_{n+1} = 1, \text{ and } |q| \leq a(y'), \\
  +\infty, & \text{otherwise}.
\end{cases}
$$

The representation formula for the solution $v^\varepsilon$ is

$$
v^\varepsilon(x', t, \omega) = \inf_{y \in \mathbb{R}^n} \left\{ v_0(y, x_{n+1} - t) : \text{there exists } \gamma : [0, \varepsilon^{-1}t] \to \mathbb{n}
\right\}
$$

such that $\gamma(0) = y$, $\gamma \left( \frac{t}{\varepsilon} \right) = \frac{x}{\varepsilon}$, and

$$
|\dot{\gamma}(s)| \leq a \left( \gamma(s), \frac{x_{n+1} - t}{\varepsilon} + s \right) \text{ for a.e } s \in (0, \varepsilon^{-1}t)
$$

for a.e. $s \in (0, \varepsilon^{-1}t)$.
Recalling the definition of the reachable set $\mathcal{R}_t(x,s)(\omega)$ in Section 2, with the associated control system (2), we rewrite the formula as

$$v^\varepsilon(x', t, \omega) = \inf_{y \in \mathbb{R}^n} \left\{ v_0(y, x_{n+1}-t) : \frac{x}{\varepsilon} \in \mathcal{R}_{\frac{t}{\varepsilon}}(\frac{x_{n+1}-t}{\varepsilon}) \left( \frac{y}{\varepsilon}, \frac{x_{n+1}-t}{\varepsilon} \right)(\omega) \right\} .$$

We have the following homogenization result for $v^\varepsilon$.

**Theorem 5.2.** Assume (A). Let $\bar{\Omega}$ be as defined in Theorem 2.4. Then, for each $\omega \in \bar{\Omega}$, the solution $v^\varepsilon$ of (67) converges locally uniformly in $\mathbb{R}^{n+1} \times (0, \infty)$ to the solution $\bar{v}$ of

$$\begin{cases}
\bar{v}_t + \overline{H}(D_{x'} \bar{v}) + v_{x_{n+1}} = 0 & \text{in } \mathbb{R}^{n+1} \times (0, \infty) \\
\bar{v} = v_0 & \text{on } \mathbb{R}^{n+1} \times \{0\},
\end{cases}$$

(68)

where $\overline{H}$ is defined in (25).

We only give a sketch of proof. Since the complete argument follows exactly the proof of Theorem 2.5, here we only give a sketch of proof. Comparing the representation formula of $v^\varepsilon$ with that of $u^\varepsilon$ in (56), we observe that the only complication in the former is the presence of the initial time $\frac{x_{n+1}-t}{\varepsilon}$ in the reachable set. The difficulty caused by this can be overcome, since we know precisely how the reachable sets change with respect to integral translations in time, and we can control the difference between non-integral translations and their nearest integral ones. It follows, from the proof of Theorem 2.5, that, locally uniformly for $(x', t) \in \mathbb{R}^{n+1} \times (0, \infty)$,

$$\rho \left( \left\{ y \in \mathbb{R}^n : x \in \varepsilon \mathcal{R}_{\frac{t}{\varepsilon}}(\frac{x_{n+1}-t}{\varepsilon}) \left( \frac{y}{\varepsilon}, \frac{x_{n+1}-t}{\varepsilon} \right)(\omega) \right\}, x - tD \right) \to 0.$$ 

This shows essentially that $v^\varepsilon$ converges, locally uniformly, to

$$\bar{v}(x', t) = \inf_{x - tD} v_0(y, x_{n+1} - t),$$

that is, the solution of (68).
