*Supporting Information

ABSTRACT: Pentahydroxyscirpene, a novel trichothecene-type compound, was isolated from Fusarium-inoculated rice. The structure of pentahydroxyscirpene was elucidated by 1D and 2D NMR spectroscopy and X-ray single-crystal diffraction. The conformation in solution was determined by NOESY experiments supported by quantum chemical calculations. In vitro toxicity tests showed that pentahydroxyscirpene inhibits protein synthesis as do other trichothecenes.

Trichothecenes, a major class of mycotoxins, are among the most prominent fungal secondary metabolites harmful to human and animal health, causing a range of acute and chronic symptoms.1 Toxicity studies showed that trichothecenes inhibit eukaryotic protein synthesis.2 When consumed through contaminated foods, trichothecenes are neurotoxic, immuno-suppressive, and nephrotoxic.3 Trichothecene-producing genera include Fusarium, Myrothecium, Stachybotrys, Cephalosporium, Trichoderma, and Trichothecium.4 Within the genus Fusarium, some species are important plant pathogens, causing head blight in small grain cereals and ear rot in maize.5 Surveillance studies showed that worldwide contamination of cereal grains and other feeds with Fusarium mycotoxins is of global concern.6

Over 200 trichothecenes have been reported so far, all containing a tricyclic 12,13-epoxytrichothec-9-ene core structure.7 They are divided into four groups (types A–D) according to their chemical properties.8 Type A trichothecenes include compounds containing a hydroxyl group (e.g., neosolaniol), an ester functionality (e.g., T-2 toxin), or no oxygen substituent at C8 (e.g., 4,15-diacetyloxyscirpenol). Type B trichothecenes, such as nivalenol (1) or deoxynivalenol (2), possess a carbonyl functionality at C8 (Figure 1). Type C trichothecenes have a C7/C8 epoxide, and compounds of type D have an additional macrocycle between C4 and C15.

Figure 1. Structures of important type A and B trichothecenes.
for the preparation of 3 starting from nivalenol is presented, and the proposed biosynthetic pathway of the novel mycotoxin is discussed.

During isolation of nivalenol from rice inoculated with the nivalenol producing strain IFA189 following a procedure described by Krška et al.,9 we discovered a novel trichothecene. The compound was purified as described in the Supporting Information. 3 was obtained as a crystalline, optically active compound \(\{[\alpha]_D^{24} = -36.1\ (c\ 0.2;\ \text{H}_2\text{O})\}\). The molecular formula, determined by HRMS measurement of the deprotonated ion (m/z 313.1290), was calculated to be C_{15}H_{23}O_{7} \ ([M - H]^- \text{calc} 313.1293), indicating 5 degrees of unsaturation. Due to four rings and one C=C double bond present in type A trichothecenes, we first considered 3 to be of classic type A structure having no carbonyl group at C-8. The \(^1\text{H}\) NMR spectrum (see Supporting Information) of 3 clearly displayed two methyl groups (\(\delta_H 1.08, 1.81\)), of which one is attached to an sp\(^2\) carbon (allylic position), leading to higher chemical shift of this signal. An olefinic proton at \(\delta_H 5.55\) indicated the presence of a trisubstituted double bond. Furthermore, 10 clearly separated signals between \(\delta_H 2.91\) and 4.42 were ascribable to protons geminal to an oxygen atom (OH or OR). The \(^{13}\text{C}\) NMR spectrum of 3 contained 15 carbon resonances, which were further classified by APT spectra as three quaternary carbons (including one olefinic carbon at \(\delta_C\ 140.1\)), one oxygenated quaternary carbon (\(\delta_C\ 65.7\)), one olefinic (\(\delta_C\ 123.9\)) and six oxygenated methines, two oxygenated methylenes (\(\delta_C\ 62.0, 46.8\)), and two methyl groups (\(\delta_C\ 20.8, 9.2\)). These data were consistent with the signals observed in the \(^1\text{H}\) NMR spectrum. All proton signals could be unambiguously assigned to their respective carbons through analysis of the HSQC spectrum (see Supporting Information). The structure of 3 was established based on the detailed analysis of \(^1\text{H} - ^1\text{H}\) COSY, HMBC, and NOESY measurements (Figure 3).

The configuration of 3 in solution was determined, supported by quantum chemical calculations [DFT, B3LYP, 6-311++G(d,p), methanol (IEFPCM), Gaussian 09; for further details see Supporting Information] (Figure 4A). X-ray single-crystal diffraction of 3 with Mo Kα radiation confirmed the proposed structure (Figure 4B; for further details see the Supporting Information). Furthermore UV and CD measurements were performed for comparison of 1, 2, and 3 (Figure 5).

To elucidate the origin of 3 as well as to ensure that this compound is not an artifact or degradation product, the whole fermentation process using the same Fusarium strain was repeated on rice. Both nivalenol (1) and pentahydroxyscirpene (3) were detected in the cultures.

3 does not contain a chromophoric moiety (Figure 5A) and may therefore be missed by routine analysis using LC-UV.

Since 3 contains an epoxide functionality, which plays an important part in the toxicity of trichothecenes,\(^{10}\) this natural compound was predicted to be toxic. In vitro toxicity tests, chosen based on the inhibition of protein synthesis by trichothecenes, were performed with 3 as well as with 1 and 2. Translation in rabbit reticulocyte lysates\(^{11}\) was suppressed to 50% (IC_{50}) at 5.0 \(\mu\text{M}\) 3, 2.0 \(\mu\text{M}\) 1, and 1.8 \(\mu\text{M}\) 2 (Figure 6).

Furthermore, a fast and simple procedure for the synthesis of 3 starting from commercially available 1 was developed (Scheme 1A). The prepared 3 was identical (NMR, \([\alpha]_D^{25}\)\(_{D}\) HRMS/MS) with the isolated material, proving the absolute configuration as shown in Scheme 2A. The stereochemistry of this Luche reduction\(^{12}\) can be explained by the Gram chelation model\(^{13}\) and/or substrate-controlled hydride addition (Scheme 1B).

A biogenetic pathway of 3 is proposed based on previously described routes to type A and B trichothecenes (Scheme 2).\(^{14}\) The biosynthetic precursor of 1 and 3 is most likely 7,8-dihydroxy-3,4,15-triacetoxy-scirpenol (7,8-dihydroxy-TAS). An unknown oxidoreductase plays an important role in the production of 1 and 3. This enzyme is predicted to catalyze the oxidation of the C8-OH, to form the acyloin moiety that is typically present in type B trichothecenes produced by various.
**Fusarium** species. In case the dehydrogenation of 7,8-dihydroxy-TAS at the C8-OH is limiting, deacetylation leads to the formation of 3.

With pentahydroxyscirpene (3) available, it should become possible to purify the enzyme performing the conversion of the C8-OH into a keto group leading to the biosynthesis of mycotoxins of the important class B trichothecenes.

### EXPERIMENTAL SECTION

#### General Experimental Procedures.

Thin-layer chromatography (TLC) was performed over silica gel 60 F254 (Merck). The chromatograms were visualized by heat staining with ceric ammonium molybdate in ethanol–sulfuric acid. LC-ESIMS/MS was performed on an HCT ion trap mass spectrometer (Bruker, Germany) in full scan mode. Chromatographic separation was done on a 1200 series HPLC system (Agilent Technologies, Germany) using a Luna RP-C18 column (3.0 × 150 mm, 3 μm particle size, Phenomenex, Germany), and application of pure substances was achieved using a TLC-MS interface (Camag, Germany). Preparative column chromatography was performed on silica gel 60 (40–63 μm, Merck, Germany) using a SepapartTM Flash System (Buchi, Switzerland). HRMS and HRMS/MS spectra were obtained on a 6550 iFunnel QTOF (Agilent Technologies) using negative electrospray ionization (ESI). The 1290 UHPLC system equipped with a Zorbax SB C18 rapid-resolution high-definition column (150 × 2.1 mm; 1.8 μm particle size) (Agilent Technologies) was used with a methanol–water gradient containing 0.1% formic acid. 1H and 13C NMR spectra were recorded on an Avance DRX-400 MHz spectrometer (Bruker, Germany). Data were recorded and evaluated using TOPSPIN 1.3 (Bruker Biospin). All chemical shifts are given in ppm relative to tetramethylsilane. The calibration was done using residual solvent signals. UV spectra were recorded by using a Shimadzu UV-1800 UV spectrophotometer. Each sample was first measured within the range 190–800 nm. Since no absorption was observed in the range 400–800 nm, all samples were measured twice in the range 190–400 nm. CD spectra were recorded with a JASCO J-815 CD spectrophotometer with a N2 monitor. The nitrogen flow was maintained at 3 L/min. After background measurement triplicates of each sample were recorded and mean values were used for visualization. Nivalenol (1) and deoxynivalenol (2) were obtained from Romer Laboratories (Tulln), and all other chemicals were purchased from Sigma-Aldrich (Austria/Germany).

**Fermentation and Purification.** Following a previously described procedure,9 the *Fusarium* strain IFA189 was cultivated in a liquid synthetic nutrient-poor medium, based on SNA (synthetic nutrient-poor agar), but without the addition of agar, for 48 h after inoculation with mycelium. Rice was inoculated with the spores and mycelium obtained suspension and incubated in the dark at 28 °C for 28 days. At the end of the incubation period, 1 kg of culture material was freeze-dried over a period of 72 h and the residue obtained was extracted with 2 L of methanol. After soaking overnight, the solution was filtered and the extraction solvent was evaporated. The remaining oily residue was dissolved in a minimum amount of methylene chloride for preparative silica gel chromatography (150 g of silica gel, CHCl3–MeOH, 90:10). After application of the diluted raw extract, the substances were eluted with the same solvent mixture as described above. The eluate was collected automatically with a fraction collector, and all fractions (20 mL) were analyzed by TLC. Appropriate fractions were pooled and concentrated on a rotary evaporator to transfer the crude mixture of 1 and 3 dissolved in approximately 10 mL of CH2Cl2–MeOH (2:1). After addition of 0.75 g of silica gel and a short shaking period the solvent was removed and the remaining material was transferred to an 8 g chromatography column, which was successively filled up with silica gel and connected to another 8 g silica gel column. The toxins were eluted (CH2Cl2–MeOH, 90:10, 10 mL/min, 5 mL fraction size), and appropriate fractions were identified by heat staining after TLC analysis (CH2Cl2–MeOH = 90/10, Rf (3) = 0.17, Rf (1) = 0.25).

**Physical Properties of 3.** Pentahydroxyscirpene (3): colorless crystals; mp 124–125 °C; [α]25° D = –36.097 (c 0.2; H2O); TLC (CHCl3–MeOH = 90/10) Rf 0.17; HRMS m/z 313.1290 ([M–H]+, calculated for C19H18O13 313.1293). 1H NMR (400 MHz, CD3OD) δ 5.55 (d, J = 5.6, 12 Hz, 1H, H-10), 4.42 (d, J = 5.0 Hz, 1H, H-7), 4.26 (d, J = 3.2 Hz, 1H, H-4), 4.14 (d, J = 5.9 Hz, 1H, H-11), 4.04 (t, J = 4.1 Hz, 1H, H-3), 3.93 (d, J = 12.6 Hz, 1H, H-15), 3.87 (d, J = 5.0 Hz, 1H, H-8), 3.65 (d, J = 12.6 Hz, 1H, H-15), 3.40 (d, J = 4.7 Hz, 1H, H-2), 3.02 (d, J = 4.4 Hz, 1H, H-13), 2.91 (d, J = 4.4 Hz, 1H, H-13), 1.81 (d, J = 1.2 Hz, 3H, CH3-16), 1.08 (s, 3H, CH3-14). 13C NMR (100 MHz, CD3OD) δ 140.1 (s, 1C, C-9), 123.9 (d, 1C, C-10), 82.3 (d, 1C, C-4), 81.2 (d, 1C, C-2), 80.7 (d, 1C, C-3), 72.2 (d, 1C, C-7), 72.1 (d, 1C, C-8), 71.2 (d, 1C, C-7), 65.7 (s, 1C, C-12), 62.0 (t, 1C, C-15), 50.7 (s, 1C, C-5), 49.4 (s, 1C, C-6), 46.8 (t, 1C, C-13), 20.8 (q, 1C, C-16), 9.2 (q, 1C, C-14).

**Inhibition of Protein Synthesis in Rabbit Reticulocyte Lysates.** The effect of 1, 2, and 3 on mammalian ribosomes was tested in a rabbit reticulocyte lysate-coupled in vitro transcription/translation system (TnT T3 coupled reticulocyte lysate system, Promega) using the newly translated luciferase as a reporter for translational activity. The transcription/translation reactions were performed in a total volume of 15 μL for 20 min according to the manufacturer’s instructions in the presence of either 1, 2, or 3, respectively or water as a control. The translation reactions were stopped by the addition of 1 μL of 1 M cycloheximide. Efficiency of translation was determined by measuring activity of the firefly luciferase reporter (Steady-Glo luciferase assay system, Promega) using the 2300 EnSpireMultimode plate reader (PerkinElmer). Two independent experiments were performed using the separately produced dilutions of the mycotoxins in water.
X-ray Single-Crystal Diffraction (CCDC 933314). A crystal of the monohydrate of 3 was embedded in perfluorinated oil and attached to a Kapton mount. Intensity data were collected on a Bruker KAPPA APEX II diffractometer equipped with a CCD detector in o- and ϕ-scan modes with 1° frame width using Mo Kα radiation. The full reciprocal sphere up to 2θ = 60° was collected. The frames were reduced to intensity values using SAINT-Plus, and absorption correction was applied using the multiscan approach implemented in SADABS. The structure was solved using charge flipping implemented in SUPERFLIP, and refined against F with JANA2006. The H atoms were located in the difference Fourier maps. C-H atoms were refined as riding on the parent C atoms, and the O-H distances were restrained to 0.820(1) Å. The absolute configuration was deduced by synthesis from a precursor with known chiral centers. The monohydrate of the title compound crystallizes in space group P212121 with one crystallographically unique molecule of 3 and water, respectively. As expected, the molecular conformation and the packing are defined by strong O-H···O hydrogen bonds (Table S1, Supporting Information): The molecular conformation is stabilized by one intramolecular hydrogen bond. Each molecule connects to three other molecules. The water molecule donates two and the acceptor one hydrogen bond. Thus an intricate three-dimensional network is formed.

Preparation of 3 by Stereoselective Luche Reduction of 1. Nivalenol (10.0 mg, 0.032 mmol) and CeCl₃·7H₂O (23.9 mg, 0.064 mmol) were dissolved in dry MeOH (3 mL). NaBH₄ (2.4 mg, 0.064 mmol) was added, and the reaction mixture was stirred for 60 min at room temperature. The solvent was evaporated, and the remaining residue was dissolved in 2 mL of H₂O−MeOH (95:5). Purification using RP-HPLC (H₂O−MeOH gradient elution) afforded 7.2 mg (72%) of 3 as a white solid. The obtained compound was identical (NMR, [α]D, HRMS/MS) with the isolated material.
