Abstract

A necessary condition is established for a function to be in the image of a quantum
Poisson integral operator associated to the Shilov boundary of the quantum matrix ball. A
quantum analogue of the Hua equations is introduced.

Key words: quantum matrix ball, Shilov boundary, Poisson integral operator, invariant
kernel, Hua equations.

Mathematics Subject Classification 2000: 81R50 (primary); 17B37, 31B10 (secondary).

Dedicated to the memory of L. L. Vaksman

1 Introduction

In late 90ies three groups of specialists advanced in putting the basics of the quantum
theory of bounded symmetric domains.

T. Tanisaki and his team introduced q-analogs for prehomogeneous vector spaces of
commutative parabolic type and found an explicit form of the associated Sato-Bernstein
polynomials [18, 17, 21, 16] .

On the other hand, H. Jakobsen suggested a less intricate method of producing the
above quantum vector spaces. Actually he was on the way to quantum Hermitian sym-
metric spaces of non-compact type [12, 13] . A similar approach is used in the work by
W. Baldoni and P. Frajria [11] on q-analogs of algebras of invariant differential operators
and the Harish-Chandra homomorphism for these quantum symmetric spaces. During
the same period Jakobsen obtained a description of all the unitarizable highest weight
modules over the Drinfeld-Jimbo algebras [11] .

The authors listed above made no use of the full symmetry of the quantum prehomog-
eneous vector spaces in question [36, 31] , which became an obstacle in producing the
quantum theory of bounded symmetric domains.

*Partially supported by a grant of the President of Ukraine
The paper \cite{37} laid the foundations of this theory. The subsequent results have been obtained in the works of L. Vaksman, D. Proskurin, S. Sinel’shchikov, A. Stolin, D. Shklyarov, L. Turowska, H. Zhang \cite{39, 23, 34, 42, 30, 41, 32}. The compatibility of the approaches described above \cite{38, 11, 37} has been proved by Shklyarov \cite{26}. The study of quantum analogs for the Harish-Chandra modules related to quantum bounded symmetric domains and their geometric realizations has been started in \cite{27, 35, 28}. The present work proceeds with this research.

Recall that a bounded domain $D$ in a finite dimensional vector space is said to be symmetric if every point $p \in D$ is an isolated fixed point of a biholomorphic involutive automorphism $\varphi_p : D \to D$, $\varphi_p \circ \varphi_p = \text{id}$.

Equip the vector space of linear maps in $\mathbb{C}^n$ and the canonically isomorphic vector space $\text{Mat}_n$ of complex $n \times n$ matrices with the operator norms. It is known \cite{8} that the unit ball $D = \{z \in \text{Mat}_n | \text{zz}^* < 1\}$ is a bounded symmetric domain.

Denote by $S(D)$ the Shilov boundary of $D$, $S(D) = \{z \in \text{Mat}_n | I - \text{zz}^* = 0\} \sim U_n$. It is well known that both $D$ and $S(D)$ are homogeneous spaces of the group $SU_{n,n}$. Consider a function on $D \times S(D)$ given by

$$P(z, \zeta) = \frac{\det(1 - \text{zz}^*)^n}{|\det(1 - \zeta^*z)|^{2n}} , \quad z \in D, \quad \zeta \in S(D). \quad (1.1)$$

It is called the Poisson kernel \cite{10} associated to the Shilov boundary.

The general concepts on boundaries of Hermitian symmetric spaces of non-compact type and the associated Poisson kernels are exposed in \cite{20, 19}.

The Poisson kernel, together with the $S(U_n \times U_n)$-invariant integral $\int_{U_n} \cdot d\nu(\zeta)$ on $U_n$, allow one to define the Poisson integral operator

$$P : f(\zeta) \mapsto \int_{U_n} P(z, \zeta) f(\zeta) d\nu(\zeta), \quad z \in D, \quad \zeta \in S(D).$$

It intertwines the actions of $SU_{n,n}$ in the spaces of continuous functions on the domain $D$ and on the Shilov boundary $S(D)$. However, not every continuous function on $D$ can be produced via applying the Poisson integral operator to a continuous function on the Shilov boundary $S(D)$.

Hua \cite{10} obtained the initial results on differential equations whose solutions include the functions of the form $P(f)$. A later result of Johnson and Korányi \cite{15} provided a system of differential equations which give a complete characterization of such functions. Their version of the Hua equations is as follows:

$$\sum_{i,j,k=1}^n \left( \delta_{ij} - \sum_{c=1}^n z^i_c z^j_c \right) \left( \delta_{k\alpha} - \sum_{c=1}^n \bar{z}^k_{c\alpha} \bar{z}^\alpha_c \right) \frac{\partial^2}{\partial \bar{z}_j^c \partial z^\alpha_i} u(z) = 0,$$

$$\sum_{i,j,k=1}^n \left( \delta_{ai} - \sum_{c=1}^n z^i_c \bar{z}_i^c \right) \left( \delta_{jk} - \sum_{c=1}^n \bar{z}^j_k \bar{z}^\alpha_c \right) \frac{\partial^2}{\partial \bar{z}_i^c \partial z^\alpha_k} u(z) = 0$$

for $a, \alpha = 1, \ldots, n$.

This can be also represented in the form:

$$\sum_{c=1}^n \frac{\partial^2 u(g \cdot z)}{\partial z_c^\beta \partial \bar{z}_c^\alpha} \bigg|_{z=0} = 0, \quad g \in SU_{n,n}, \quad \alpha, \beta \in \{1, 2, \ldots, n\}. \quad (1.2)$$
It is known that the Poisson kernel (1.1) as a function of $z$ is a solution of the above equation system. While proving this, one may stick to the special case $g = 1$ because $P(gz, \zeta) = \text{const}(g, \zeta)P(z, g^{-1}\zeta)$, cf. [15, p. 597]. What remains is to note that the relations

$$
\sum_{c=1}^{n} \frac{\partial^2 P}{\partial z_\alpha \partial z_\beta} \bigg|_{z=0} = 0, \quad \zeta \in U_n, \quad \alpha, \beta \in \{1, 2, \ldots, n\}
$$

(1.3)

follow from (1.1).

Thus in the classical case the Poisson integral operator applied to a function on the Shilov boundary is a solution of (1.2). We are going to obtain a quantum analog of this well known result.

This work suggests a quantum analog for the Hua equations. We thus get a quantization of the necessary condition for a function being a Poisson integral of a function on the Shilov boundary.

The authors acknowledge that the ideas of this work have been inspired by plentiful long term communications with L. Vaksman. Also, we would like to express our gratitude to D. Shklyarova for pointing out several inconsistencies in a previous version of this work, and encouraging us to improve the exposition.

2 A background on function theory in quantum matrix ball

In what follows we assume $\mathbb{C}$ to be the ground field and all the algebras are assumed associative and unital.

Recall the construction of the quantum universal enveloping algebra for the Lie algebra $\mathfrak{sl}_N$. The quantum universal enveloping algebras were introduced by V. Drinfeld and M. Jimbo in an essentially more general way than it is described below. We follow the notation of [11, 15, 14, 25].

Let $q \in (0, 1)$. The Hopf algebra $U_q \mathfrak{sl}_N$ is given by its generators $K_i, K_i^{-1}, E_i, F_i$, $i = 1, 2, \ldots, N-1$, and the relations:

$$
K_iK_j = K_jK_i, \quad K_iK_i^{-1} = K_i^{-1}K_i = 1,
$$

$$
K_iE_j = q^{a_{ij}}E_jK_i, \quad K_iF_j = q^{-a_{ij}}F_jK_i,
$$

$$
E_iF_j - F_jE_i = \delta_{ij}K_i - K_i^{-1},
$$

$$
E_i^2E_j - (q + q^{-1})E_iE_jE_i + E_jE_i^2 = 0, \quad |i - j| = 1,
$$

$$
F_i^2F_j - (q + q^{-1})F_iF_jF_i + F_jF_i^2 = 0, \quad |i - j| = 1,
$$

$$
E_iE_j - E_jE_i = F_iF_j - F_jF_i = 0, \quad |i - j| \neq 1,
$$

with $a_{ii} = 2$, $a_{ij} = -1$ for $|i - j| = 1$, $a_{ij} = 0$ otherwise, and the comultiplication $\Delta$, the antipode $S$, and the counit $\varepsilon$ being defined on the generators by

$$
\Delta(E_i) = E_i \otimes 1 + K_i \otimes E_i, \quad \Delta(F_i) = F_i \otimes K_i^{-1} + 1 \otimes F_i, \quad \Delta(K_i) = K_i \otimes K_i,
$$

$$
S(E_i) = -K_i^{-1}E_i, \quad S(F_i) = -F_iK_i, \quad S(K_i) = K_i^{-1},
$$

$$
\varepsilon(E_i) = \varepsilon(F_i) = 0, \quad \varepsilon(K_i) = 1,
$$

with $a_{ii} = 2$,
see also [14, Chapter 4].

Consider the Hopf algebra $U_q \mathfrak{sl}_{2n}$. Equip $U_q \mathfrak{sl}_{2n}$ with a structure of Hopf $\ast$-algebra determined by the involution

$$K_j^\ast = K_j, \quad E_j^\ast = \begin{cases} K_j F_j, & j \neq n, \\ -K_j F_j, & j = n, \end{cases} \quad F_j^\ast = \begin{cases} E_j K_j^{-1}, & j \neq n, \\ -E_j K_j^{-1}, & j = n. \end{cases}$$

This Hopf $\ast$-algebra $(U_q \mathfrak{sl}_{2n}, \ast)$ is denoted by $U_q \mathfrak{su}_{n,n}$. Denote by $U_q \mathfrak{t} = U_q \mathfrak{sl}(\mathfrak{u}_n \times \mathfrak{u}_n)$ the Hopf $\ast$-subalgebra generated by

$$E_i, F_i, \quad i \neq n; \quad K_j^{\pm 1}, \quad j = 1, 2, \ldots, 2n - 1.$$ 

Now we introduce the notation to be used in the sequel, and recall some known results on the quantum matrix ball $\mathbb{D}$. Consider a $\ast$-algebra $\text{Pol}(\text{Mat}_n)_q$ with generators $\{z^\alpha_a\}_{a, \alpha = 1, 2, \ldots, n}$ and defining relations

$$z^\alpha_a z^\beta_b = \begin{cases} q^{\alpha_b - \alpha_a} z^\beta_a, & a = b \& \alpha < \beta \quad \text{or} \quad a < b \& \alpha = \beta \\ z^\beta_b z^\alpha_a, & a < b \& \alpha > \beta \\ z^\beta_b z^\alpha_a + (q - q^{-1}) z^\beta_a z^\alpha_b, & a < b \& \alpha < \beta, \end{cases}$$

for $1 \leq a, b \leq n$.

The $\ast$-algebra $\{z^\alpha_a\}_{a, \alpha = 1, 2, \ldots, n}$ carries a structure of Hopf $\ast$-algebra if the involutions are compatible as follows:

$$(af)^\ast = (S(a))^\ast f^\ast, \quad a \in A, \quad f \in F,$$

with $S$ being the antipode of $A$.

It was demonstrated in [33], see Propositions 8.12 and 10.1, that one has

**Proposition 2.1** $\mathbb{C}[\text{Mat}_n]_q$ carries a structure of $U_q \mathfrak{sl}_{2n}$-module algebra given by

$$K_n^{\pm 1} z^\alpha_a = \begin{cases} q^{\pm 2} z^\alpha_a, & a = \alpha = n, \\ q^{\pm 1} z^\alpha_a, & a = n \& \alpha \neq n \text{ or } a \neq n \& \alpha = n, \\ z^\alpha_a, & \text{otherwise}, \end{cases}$$

$$F_n z^\alpha_a = q^{1/2} \begin{cases} 1, & a = \alpha = n, \\ 0, & \text{otherwise}, \end{cases}$$
and for \( k \neq n \)

\[
E_k z_a^\alpha = q^{-1/2} \cdot \begin{cases}
q^{-1} z_a^\alpha, & a \neq n \& \alpha \neq n, \\
(z_n^a)^2, & a = \alpha = n, \\
z_n^{\alpha} z_a^{-1}, & \text{otherwise,}
\end{cases}
\]

Also \( \text{Pol(Mat}_n)_q \) is equipped this way with a structure of \( U_q \text{su}_{n,n} \)-module algebra.

It is well known that in the classical case \( q = 1 \) the Shilov boundary of the matrix ball \( \mathbb{D} \) is just the set \( S(\mathbb{D}) \) of all unitary matrices. Our intention is to produce a \( q \)-analogue of the Shilov boundary for the quantum matrix ball. Introduce the notation for the quantum minors of the matrix \( z = (z_a^\alpha) \):

\[
(z_{\{a_1,a_2,\ldots,a_k\}}^\alpha)_{\{1,2,\ldots,n\}} \overset{\text{def}}{=} \sum_{s \in S_k} (-q)^{l(s)} z_{a_1}^{\alpha_{s(1)}} z_{a_2}^{\alpha_{s(2)}} \cdots z_{a_k}^{\alpha_{s(k)}},
\]

with \( \alpha_1 < \alpha_2 < \ldots < \alpha_k, a_1 < a_2 < \ldots < a_k \), and \( l(s) \) being the number of inversions in \( s \in S_k \).

It is well known that the quantum determinant

\[
\text{det}_q z = (z_{\{1,2,\ldots,n\}}^\alpha)^{-1}
\]

is in the center of \( \mathbb{C}[\text{Mat}_n]_q \). The localization of \( \mathbb{C}[\text{Mat}_n]_q \) with respect to the multiplicative system \( (\text{det}_q z)^N \) is called the algebra of regular functions on the quantum \( GL_n \) and is denoted by \( \mathbb{C}[GL_n]_q \).

**Lemma 2.2 (Lemma 2.1 of [41])** There exists a unique involution \( * \) in \( \mathbb{C}[GL_n]_q \) such that

\[
(z_a^\alpha)^* = (-q)^{a + \alpha - 2n} (\text{det}_q z)^{-1} \text{det}_q z_a^\alpha,
\]

with \( z_a^\alpha \) being the matrix derived from \( z \) via deleting the row \( \alpha \) and the column \( a \).

The \( * \)-algebra \( \mathbb{C}[S(\mathbb{D})]_q = (\mathbb{C}[GL_n]_q, *) \) is a \( q \)-analogue of the algebra of regular functions on the Shilov boundary of the matrix ball \( \mathbb{D} \). It can be verified easily that \( \mathbb{C}[S(\mathbb{D})]_q \) is a \( U_q \text{su}_{n,n} \)-module algebra (see [41], Theorem 2.2 and Proposition 2.7) for the proof).

There exists another definition of the algebra \( \mathbb{C}[S(\mathbb{D})]_q \).
Consider the two-sided ideal $J$ of the $*$-algebra $\text{Pol}(\text{Mat}_n)_q$ generated by the relations
\[\sum_{j=1}^{n} q^{2n-\alpha-\beta} z_j^{\alpha}(z_j^*)^\beta - \delta^{\alpha\beta} = 0, \quad \alpha, \beta = 1, 2, \ldots, n. \tag{2.2}\]

One can prove that this ideal is $U_q\mathfrak{su}_{n,n}$-invariant, which allows to introduce the $U_q\mathfrak{su}_{n,n}$-module algebra $\text{Pol}(\text{Mat}_n)_q/J$. It was proved in [11, p. 381, Proposition 6.1] that $\mathbb{C}[S(D)]_q = \text{Pol}(\text{Mat}_n)_q/J$. The last equality also works as a definition for the algebra of regular functions on the Shilov boundary of the quantum matrix ball.

A module $V$ over $U_q\mathfrak{sl}_{2n}$ is said to be a weight module if
\[V = \bigoplus_{\lambda \in P} V_{\lambda}, \quad V_{\lambda} = \{v \in V \mid K_i v = q^{\lambda_i} v, \quad i = 1, 2, \ldots, 2n - 1\},\]
where $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_{2n-1})$ and $P \cong \mathbb{Z}^{2n-1}$ is the weight lattice of the Lie algebra $\mathfrak{sl}_{2n}$. A non-zero summand $V_{\lambda}$ in this decomposition is called the weight subspace for the weight $\lambda$.

We associate to every weight $U_q\mathfrak{sl}_{2n}$-module $V$ linear maps $H_i, i = 1, 2, \ldots, 2n - 1$, in $V$ such that
\[H_i v = \lambda_i v, \quad \text{iff} \quad v \in V_{\lambda}.\]

Fix the element
\[H_0 = \sum_{j=1}^{n-1} j(H_j + H_{2n-j}) + nH_n.\]

Any weight $U_q\mathfrak{sl}_{2n}$-module $V$ can be equipped with a $\mathbb{Z}$-grading $V = \bigoplus_{r} V_r$ by setting $v \in V_r$ if $H_0 v = 2rv$.

In what follows some more sophisticated spaces will be used. It is known that
\[\text{Pol}(\text{Mat}_n)_q = \bigoplus_{k,j=0}^{\infty} \mathbb{C}[\text{Mat}_n]_{q,k} \cdot \mathbb{C}[[\text{Mat}_n]]_{q,-j}.\]

Here $\mathbb{C}[[\text{Mat}_n]]_{q}$ is the subalgebra of $\text{Pol}(\text{Mat}_n)_q$ generated by $(z_0^\alpha)^*, a, \alpha = 1, 2, \ldots, n$, and $\mathbb{C}[\text{Mat}_n]_{q,k}, \mathbb{C}[\text{Mat}_n]_{q,-j}$ are the homogeneous components related to the grading
\[\text{deg}(z_0^\alpha) = 1, \quad \text{deg}(z_0^\alpha)^* = -1, \quad a, \alpha = 1, 2, \ldots, n.\]

To rephrase this, every $f \in \text{Pol}(\text{Mat}_n)_q$ is uniquely decomposable as a finite sum
\[f = \sum_{k,j \geq 0} f_{k,j}, \quad f_{k,j} \in \mathbb{C}[\text{Mat}_n]_{q,k} \cdot \mathbb{C}[[\text{Mat}_n]]_{q,-j}. \tag{2.3}\]

Note that $\dim \mathbb{C}[\text{Mat}_n]_{q,k} \cdot \mathbb{C}[[\text{Mat}_n]]_{q,-j} < \infty$.

Consider the vector space $\mathcal{D}(\mathbb{D})'_q$ of formal series of the form (2.3) with the termwise topology. The $U_q\mathfrak{sl}_{2n}$-action and the involution $*$ admit an extension by continuity from the dense linear subspace $\text{Pol}(\text{Mat}_n)_q$ to $\mathcal{D}(\mathbb{D})'_q$
\[f : \sum_{k,j=0}^{\infty} f_{k,j} \mapsto \sum_{k,j=0}^{\infty} f_{k,j}^*.\]
Moreover, $\mathcal{D}(\mathbb{D})'_q$ is a $U_q\mathfrak{sl}_{2n}$-module bimodule over $\text{Pol}(\text{Mat}_n)_q$. We call the elements of $\mathcal{D}(\mathbb{D})'_q$ distributions on a quantum bounded symmetric domain.
3 Statement of the main result

We intend to determine the Poisson kernel (1.1) by listing some essential properties of the associated integral operator. For that, we use the normalized $S(U_n \times U_n)$-invariant measure on $S(\mathbb{D})$ for integration on the Shilov boundary. The principal property of the Poisson kernel is that the integral operator with this kernel is a morphism of a $SU_{n,n}$-module of functions on $S(\mathbb{D})$ into a $SU_{n,n}$-module of functions on $\mathbb{D}$ which takes 1 to 1.

So in the quantum case the required Poisson integral operator is a morphism of the $U_q\mathfrak{su}_{n,n}$-module $\mathbb{C}[S(\mathbb{D})]_q$ into the $U_q\mathfrak{su}_{n,n}$-module $\mathcal{D}(\mathbb{D})'_q$ which takes 1 to 1.

Recall that every $u \in \mathcal{D}(\mathbb{D})'_q$ is of the form

$$u = \sum_{j,k=0}^{\infty} u_{j,k}, \quad u_{j,k} \in \mathbb{C}[\text{Mat}_n]_{q,j} \mathbb{C}[\text{Mat}_n]_{q,-k},$$

and the set $\left\{ z^\beta_b (z^\alpha_a)^* \right\}_{a,b,a,\beta=1,2,\ldots,n}$ is a basis of the vector space $\mathbb{C}[\text{Mat}_n]_{q,1} \mathbb{C}[\text{Mat}_n]_{q,-1}$.

This allows one to introduce the mixed partial derivatives at zero, the linear functionals

$$\left. \frac{\partial^2}{\partial z^\beta_b \partial (z^\alpha_a)^*} \right|_{z=0}$$

such that

$$u_{1,1} = \sum_{a,b,a,\beta=1}^{n} \left( \left. \frac{\partial^2 u}{\partial z^\beta_b \partial (z^\alpha_a)^*} \right|_{z=0} \right) z^\beta_b (z^\alpha_a)^*, \quad u \in \mathcal{D}(\mathbb{D})'_q.$$

Now we are in a position to produce a quantum analog of the Hua equations.

**Theorem 3.1** If $u \in \mathcal{D}(\mathbb{D})'_q$ belongs to the image of the Poisson integral operator on the quantum $n \times n$-matrix ball, then

$$\sum_{c=1}^{n} q^{2c} \left. \frac{\partial^2 (\xi u)}{\partial z^\beta_c \partial (z^\alpha_c)^*} \right|_{z=0} = 0$$

(3.1)

for all $\xi \in U_q\mathfrak{sl}_2n$, $\alpha, \beta = 1, 2, \ldots, n$.

The equation system (3.1) is a $q$-analog of (1.2).

4 Invariant generalized kernels and the associated integral operators

List some plausible but less known definitions and results on invariant integral and integral kernels, see [40]. Consider a Hopf algebra $A$ and an $A$-module algebra $F$. A linear functional $\nu$ on $F$ is called an $A$-invariant integral if $\nu$ is a morphism of $A$-modules:

$$\nu(af) = \varepsilon(a)f, \quad a \in A, \quad f \in F,$$

with $\varepsilon$ being the counit of $A$. 
There exists a unique $U_q\mathfrak{gl}_n \times \mathfrak{gl}_n$-invariant integral

$$\nu : \mathbb{C}[S(\mathbb{D})]_q \to \mathbb{C}, \quad \nu : \varphi \mapsto \int_{S(\mathbb{D})_q} \varphi d\nu,$$

which is normalized by $\int_{S(\mathbb{D})_q} 1 d\nu = 1$ (see [41, Chapter 3]). It was also demonstrated in [41] that $\mathbb{C}[S(\mathbb{D})]_q$ is isomorphic to the algebra of regular functions on the quantum $U_n$ as a $U_q\mathfrak{gl}_n \times \mathfrak{gl}_n$-module $*$-algebra. This isomorphism can be used to consider the transfer of $\nu$ on the latter algebra, where it is known to be positive [45]. Hence $\nu$ is itself positive:

$$\int_{S(\mathbb{D})_q} \varphi^* \varphi d\nu > 0$$

for all non-zero $\varphi \in \mathbb{C}[S(\mathbb{D})]_q$. Our subsequent results demonstrate how this $U_q\mathfrak{gl}_n \times \mathfrak{gl}_n$-invariant integral can be used to produce integral operators which are morphisms of $U_q\mathfrak{sl}_2$-modules.

Consider $A$-module algebras $F_1, F_2$. Given a linear functional $\nu : F_2 \to \mathbb{C}$ and $K \in F_1 \otimes F_2$, we associate a linear integral operator

$$K : F_2 \to F_1, \quad K : f \mapsto (\text{id} \otimes \nu)(K(1 \otimes f)).$$

In this context $K$ is called the kernel of this integral operator. Assume that the integral $\nu$ on $F_2$ is invariant and the bilinear form

$$f' \times f'' \mapsto \nu(f' f''), \quad f', f'' \in F_2,$$

is non-degenerate. It is easy to understand that the integral operator with the kernel $K$ is a morphism of $A$-modules if and only if this kernel is invariant [40]. Another statement from [40] that will be used essentially in a subsequent construction of $A$-invariant kernels is as follows: $A$-invariant kernels form a subalgebra of $F_1^{\text{op}} \otimes F_2$, with $F_1^{\text{op}}$ being the algebra derived from $F_1$ by replacement of its multiplication by the opposite one.

Additionally to the algebra of kernels $\text{Pol}(\text{Mat}_n)_{q}^{\text{op}} \otimes \mathbb{C}[S(\mathbb{D})]_q$, we will use the bimodule of generalized kernels $\mathcal{D}(\mathbb{D} \times S(\mathbb{D}))_q$ whose elements are just the formal series

$$\sum_{i,j} f_{ij} \otimes \varphi_{ij}, \quad f_{ij} \in \mathbb{C}[\text{Mat}_n]_{q}^{\text{op}}, \quad \varphi_{ij} \in \mathbb{C}[S(\mathbb{D})]_q.$$

This is a bimodule over the algebra $\text{Pol}(\text{Mat}_n)_{q}^{\text{op}} \otimes \mathbb{C}[S(\mathbb{D})]_q$.

5 A passage from affine coordinates to homogeneous coordinates

This Section, just as Sections 2 and 4, contains some preliminary material and the known results obtained in [43, 33, 41].

Turn to the quantum group $SL_N$. We follow the general idea of Drinfeld [6] in considering the Hopf algebra $\mathbb{C}[SL_N]_q$ of matrix elements of finite dimensional weight $U_q\mathfrak{sl}_N$-modules. It is custom to call it the ‘algebra of regular functions on the quantum group $SL_N$’. The linear maps in $(U_q\mathfrak{sl}_N)^*$ adjoint to the operators of left multiplication by the elements of $U_q\mathfrak{sl}_N$ equip $\mathbb{C}[SL_N]_q$ with a structure of $U_q\mathfrak{sl}_N$-module algebra by duality.
Recall that $\mathbb{C}[SL_N]^q$ can be defined by the generators $t_{ij}$, $i, j = 1, \ldots, N$, (the matrix elements of the vector representation in a weight basis) and the relations

\[
t_{ij'}t_{ij''} = qt_{ij''}t_{ij'}, \quad j' < j'',
\]
\[
t_{i'j}t_{i'j'} = qt_{i'j'}t_{i'j}, \quad i' < i'',
\]
\[
t_{ij}t_{i'j'} = t_{i'j'}t_{ij}, \quad i < i' \land j > j',
\]
\[
t_{ij}t_{i'j'} = t_{i'j'}t_{ij} + (q - q^{-1})t_{ij'}t_{i'j}, \quad i < i' \land j < j',
\]

which are tantamount to (2.1), together with one more relation

\[
det_q t = 1,
\]

where $\det_q t$ is a $q$-determinant of the matrix $t = (t_{ij})_{i,j=1,\ldots,N}$:

\[
det_q t = \sum_{s \in S_N} (-q)^{l(s)}t_{1s(1)}t_{2s(2)} \cdots t_{Ns(N)},
\]

with $l(s) = \text{card}\{(i, j)|i < j \& s(i) > s(j)\}$.

It is well known that $\det_q t$ commutes with all $t_{ij}$. Thus $\mathbb{C}[SL_N]^q$ appears to be a quotient algebra of $\mathbb{C}[^{\bigwedge}N]^q$ by the two-sided ideal generated by $\det_q t - 1$.

Note that $\mathbb{C}[SL_N]^q$ is a domain.

In the classical case $q = 1$ the matrix ball admits a natural embedding into the Grassmannian $\text{Gr}_{n,2n}$

(a contraction $A \in \text{End} \mathbb{C}^n) \mapsto (\text{the linear span of } (v, Av), \quad v \in \mathbb{C}^n),

with the latter pair being an element of $\mathbb{C}^n \oplus \mathbb{C}^n \simeq \mathbb{C}^{2n}$. We are going to describe a $q$-analog for this embedding.

Let

\[
I = \{i_1, i_2, \ldots, i_k\} \subset \{1, 2, \ldots, 2n\}, \quad i_1 < i_2 < \ldots < i_k;
\]
\[
J = \{j_1, j_2, \ldots, j_k\} \subset \{1, 2, \ldots, 2n\}, \quad j_1 < j_2 < \ldots < j_k.
\]

The elements

\[
t^{\wedge k}_{IJ} = \sum_{s \in S_k} (-q)^{l(s)}t_{i_1s(1)}t_{i_2s(2)} \cdots t_{i`s(k)},
\]

of $\mathbb{C}[SL_{2n}]^q$ are called quantum minors, and it is easy to check that

\[
t^{\wedge k}_{IJ} = \sum_{s \in S_k} (-q)^{l(s)}t_{i_1s(1)}t_{i_2s(2)} \cdots t_{i`s(k)},
\]

Consider the smallest unital subalgebra $\mathbb{C}[X]^q \subset \mathbb{C}[SL_{2n}]^q$ that contains the quantum minors

\[
t^{\wedge n}_{\{1,2,\ldots,n\}J}, \quad t^{\wedge n}_{\{n+1,n+2,\ldots,2n\}J}, \quad J = \{j_1, j_2, \ldots, j_n\} \subset \{1, 2, \ldots, 2n\}.
\]

It is a $U_q\mathfrak{sl}_{2n}$-module subalgebra which substitutes the classical coordinate ring of the Grassmannian.

The following results are easy modifications of those of 

[33].
Proposition 5.1 There exists a unique antilinear involution * in \( \mathbb{C}[X]_q \) such that \((\mathbb{C}[X]_q, \ast)\) is a \( U_q \text{su}_{n,n} \)-module algebra and

\[
(t_{\{1,2,\ldots,n\}\{n+1,n+2,\ldots,2n\}}) = (-q)^{n^2} t_{\{n+1,n+2,\ldots,2n\}\{1,2,\ldots,n\}}.
\]

Lemma 5.2 (Lemma 11.3 of [33]) Given \( J \subset \{1,2,\ldots,2n\} \) with \( \text{card}(J) = n \), \( J^c = \{1,2,\ldots,2n\} \setminus J \), \( l(J,J^c) = \text{card}\{j'\in J^c| j' > j''\} \). Then

\[
(t_{\{1,2,\ldots,n\}\{1,2,\ldots,n\}})^* = (-1)^{\text{card}(1,2,\ldots,n)\cap J} (-q)^{l(J,J^c)} t_{\{n+1,n+2,\ldots,2n\}\{1,2,\ldots,n\}}. \tag{5.1}
\]

Impose the abbreviated notation

\[
t = t_{\{1,2,\ldots,n\}\{n+1,n+2,\ldots,2n\}}, \quad x = tx^*.
\]

Note that \( t, t^* \) and \( x \) quasi-commute with all the generators \( t_{ij} \) of \( \mathbb{C}[SL_{2n}]_q \). Then the localization \( \mathbb{C}[X]_{q,x} \) of the algebra \( \mathbb{C}[X]_q \) with respect to the multiplicative set \( x^{\mathbb{Z}_+} \) is well-defined. The structure of \( U_q \text{su}_{n,n} \)-module algebra is uniquely extendable from \( \mathbb{C}[X]_q \) onto \( \mathbb{C}[X]_{q,x} \) [33].

Proposition 5.3 (cf. Proposition 3.2 of [33]) There exists a unique embedding of \( U_q \text{su}_{n,n} \)-module \( \ast \)-algebras \( I : \text{Pol(Mat}_n)_q \hookrightarrow \mathbb{C}[X]_{q,x} \) such that \( I z^\alpha = t^{-1} t_{\{1,2,\ldots,n\}\{a_1,\ldots,a_k\}} \), with \( J_{a_\alpha} = \{a\} \cup \{n+1, n+2, \ldots, 2n\}\{2n+1-\alpha\} \).

Corollary 5.4 \( I y = x^{-1} \), with

\[
y = 1 + \sum_{k=1}^m (-1)^k \sum_{\{J'\text{ card}(J') = k\}} \sum_{\{J''\text{ card}(J'') = k\}} z^k j' (z^{k} j')^*. \tag{5.2}
\]

A formal passage to a limit as \( q \to 1 \) leads to the relation \( y = \det(1 - zz^*) \).

Proposition 5.5 (see Chapter 11 of [33]) Let \( 1 \leq \alpha_1 < \alpha_2 < \ldots < \alpha_k \leq n \), \( 1 \leq a_1 < a_2 < \ldots < a_k \leq n \), \( J = \{n+1,n+2,\ldots,2n\}\{n+1, n+2,\ldots, n+\alpha_k\} \cup \{a_1, a_2, \ldots, a_k\} \).

Then

\[
I z_{\{a_1,a_2,\ldots,a_k\}} = t^{-1} t_{\{1,2,\ldots,n\}\{n+1, n+2,\ldots, n+\alpha_k\}}. \tag{5.3}
\]

It is custom to identify the generators \( z^\alpha_{a} \), \( a, \alpha = 1,2,\ldots,n \), with their images under \( I \).

Consider the subalgebra of \( \mathbb{C}[X]_{q,x} \) generated by \( \text{Pol(Mat}_n)_q \hookrightarrow \mathbb{C}[X]_{q,x} \), together with \( t^{\pm 1}, t^{*\pm 1} \).

The elements of this subalgebra admit a unique decomposition of the form

\[
\sum_{(i,j)\in\{1,2,\ldots,n\}^2} t^{ij} f_{ij}, \quad f_{ij} \in \text{Pol(Mat}_n)_q \tag{5.4}
\]

(the choice of the set of pairs \( (i,j) \) is due to the fact that \( t^{-1} t^{*} - 1 \in \text{Pol(Mat}_n)_q \)).

Equip \( \mathbb{C}^n \oplus \mathbb{C}^n \) with the sesquilinear form \( \langle \cdot, \cdot \rangle_1 - \langle \cdot, \cdot \rangle_2 \). In the classical case \( q=1 \) the Shilov boundary of the matrix ball is just the group \( U_n \). The graphs of unitary operators form the isotropic Grassmannian (its points are just the subspaces on which the above scalar product on \( \mathbb{C}^{2n} \) vanishes). We are going to describe a \( q \)-analog of it, with the isotropic Grassmannian being replaced by its homogeneous coordinate ring.
Consider an extension $\mathbb{C}[\Xi]_q$ of the algebra $\mathbb{C}[S(\mathbb{D})]_q$ in the class of $U_q\mathfrak{su}_{n,n}$-module $*$-algebras. This extension is produced via adding a generator $t$ and the relations

$$tt^* = t^*t; \quad tz^\alpha = q^{-1}z^\alpha t; \quad t^*z^\alpha = q^{-1}z^\alpha t^*, \quad \alpha = 1, 2, \ldots, n. \quad (5.5)$$

The $U_q\mathfrak{su}_{n,n}$-action is extended onto $\mathbb{C}[\Xi]_q$ as follows:

$$E_jt = F_jt = (K_j^{\pm 1} - 1)t = 0, \quad j \neq n,$$

$$F_nt = (K_n^{\pm 1} - 1)t = 0, \quad E_nt = q^{-1/2}tz_n^n.$$

Let $\xi = tt^*$. One can introduce a localization $\mathbb{C}[\Xi]_{q,\xi}$ of the algebra $\mathbb{C}[\Xi]_q$ with respect to the multiplicative set $\xi^{\mathbb{Z}^+}$. The involution $*$ and the structure of $U_q\mathfrak{su}_{n,n}$-module algebra are uniquely extendable from $\mathbb{C}[\Xi]_q$ onto $\mathbb{C}[\Xi]_{q,\xi}$.

The algebra $\mathbb{C}[\Xi]_q$ is equipped with a $U_q\mathfrak{sl}_{2n}$-invariant bigrading

$$\deg z^\alpha = \deg(z^\alpha)^* = (0, 0), \quad \deg t = (1, 0), \quad \deg t^* = (0, 1),$$

which extends onto the localization $\mathbb{C}[\Xi]_{q,\xi}$. It was demonstrated in [41] that the homogeneous component $\mathbb{C}[\Xi]_{q,\xi}^{(-n,-n)}$ carries a non-zero $U_q\mathfrak{sl}_{2n}$-invariant integral $\eta$ such that

$$\eta(t^{*-n}ft^{-n}) = \int_{S(\mathbb{D})_q} f d\nu.$$

Since $t, t^*$ normalize every $U_q\mathfrak{sl}(u_n \times u_n)$-isotypical component of $\mathbb{C}[S(\mathbb{D})]_q$ and the $U_q\mathfrak{sl}(u_n \times u_n)$-action in $\mathbb{C}[S(\mathbb{D})]_q$ is multiplicity free [3, Proposition 4], it follows from the definition of the integral over the Shilov boundary that

$$\eta(t^{*-n}ft^{-n}) = \eta(f^{t*-n}t^{-n}) = \int_{S(\mathbb{D})_q} f d\nu. \quad (5.6)$$

6 The Poisson kernel

In this Section we construct a morphism of the $U_q\mathfrak{su}_{n,n}$-module $\mathbb{C}[S(\mathbb{D})]_q$ into the $U_q\mathfrak{su}_{n,n}$-module $\mathcal{D}(\mathbb{D})'_q$ which takes 1 to 1. The introduced morphism will be a Poisson integral operator, as mentioned in Section 3.

We will need a quantum analog $\mathbb{C}[\text{Mat}_{n,2n}]_q$ for the polynomial algebra on the space of rectangular $n \times 2n$-matrices. The algebra $\mathbb{C}[\text{Mat}_{n,2n}]_q$ is determined by the set of generators $\{t_{ij}\}_{i=1,2,\ldots,n; j=1,2,\ldots,2n}$ and the similar relations as in the case of square matrices, see (2.1). It is known that this algebra is a domain.

The structure of $U_q\mathfrak{sl}_{2n}$-module algebra is given by

\begin{equation*}
K_kt_{ij} = \begin{cases} 
qt_{ij}, & j = k, \\
q^{-1}t_{ij}, & j = k + 1, \\
t_{ij}, & j \notin \{k, k + 1\}, 
\end{cases}
\end{equation*}

\begin{equation*}
E_kt_{ij} = \begin{cases} 
q^{-1/2}t_{i,j-1}, & j = k + 1, \\
0, & j \neq k + 1, 
\end{cases}
\end{equation*}

\begin{equation*}
F_kt_{ij} = \begin{cases} 
qu^{1/2}t_{i,j+1}, & j = k, \\
0, & j \neq k, 
\end{cases}
\end{equation*}

with $k = 1, 2, \ldots, 2n - 1$. 
Remark 6.1 Consider the $U_q \mathfrak{sl}_{2n}$-module subalgebras in $\mathbb{C}[\text{Mat}_{n,2n}]_q$ and in $\mathbb{C}[\Xi]_q$ generated by $\{1,2,\ldots,n\}^{n+1,2n}$ and $t$, respectively. The map $t^{\wedge n}_{\{1,2,\ldots,n\}} \{1,2,\ldots,n\}^{n+1,2n} \mapsto t$ extends up to an isomorphism $i$ of these $U_q \mathfrak{sl}_{2n}$-module subalgebras. In a similar way, one can introduce $U_q \mathfrak{sl}_{2n}$-module subalgebras in $\mathbb{C}[\text{Mat}_{n,2n}]_q$ and in $\mathbb{C}[\Xi]_q$, generated by $\{1,2,\ldots,n\}^{n+1,2n}$ and $t^*$, respectively. The map $t^{\wedge n}_{\{1,2,\ldots,n\}} \{1,2,\ldots,n\} \mapsto (-q)^{n^2} t^*$ extends up to an isomorphism $i'$ of these $U_q \mathfrak{sl}_{2n}$-module subalgebras. The above isomorphisms can be used together to embed minors $t^{\wedge n}_{\{1,2,\ldots,n\} J}$ and $t^{\wedge n}_{\{n+1,2n\} J}$ into $\mathbb{C}[\Xi]_q$.

Consider the map $m : \mathbb{C}[\text{Mat}_{n,2n}]_q \otimes \mathbb{C}[\text{Mat}_{n,2n}]_q \to \mathbb{C}[\text{Mat}_{2n}]_q$ defined as follows. The tensor multipliers of the domain are embedded into $\mathbb{C}[\text{Mat}_{2n}]_q$ as subalgebras generated by the entries of, respectively, the upper $n$ and the lower $n$ rows of the matrix $t = (t_{ij})$, $i = 1, \ldots, n$, $j = 1, \ldots, 2n$, and the map $m$ is just the multiplication in the algebra $\mathbb{C}[\text{Mat}_{2n}]_q$.

Lemma 6.2 The map $m$ is an isomorphism of $U_q \mathfrak{sl}_{2n}$-modules.

Proof. The map $m$ takes the monomial basis

$$t^{j_1}_{11} \ldots t^{j_2}_{12,2} \ldots t^{j_n}_{n,2n} \otimes t^{j_{n+1}}_{n+1,1} \ldots t^{j_{n+2}}_{n+2,2n} + \ldots + t^{j_{n+2}}_{n+2,2n} \otimes t^{j_{n+1}}_{n+1,1} \ldots t^{j_1}_{11}$$

of the algebra $\mathbb{C}[\text{Mat}_{n,2n}]_q \otimes \mathbb{C}[\text{Mat}_{n,2n}]_q$ to the monomial basis

$$t^{j_1}_{11} \ldots t^{j_2}_{12,2} \ldots t^{j_n}_{n,2n} \otimes t^{j_{n+1}}_{n+1,1} \ldots t^{j_{n+2}}_{n+2,2n} + \ldots + t^{j_{n+2}}_{n+2,2n} \otimes t^{j_{n+1}}_{n+1,1} \ldots t^{j_1}_{11}$$

of the algebra $\mathbb{C}[\text{Mat}_{2n}]_q$, $j_{ik} \in \mathbb{Z}_+$, hence is a bijective map. It is a morphism of $U_q \mathfrak{sl}_{2n}$-modules since $\mathbb{C}[\text{Mat}_{2n}]_q$ is a $U_q \mathfrak{sl}_{2n}$-module algebra. \hfill $\square$

It is worthwhile to note that the definition of the $U_q \mathfrak{sl}_{2n}$-module algebra $\mathbb{C}[X]_q$ allows a replacement of $\mathbb{C}[\text{SL}_{2n}]_q$ by $\mathbb{C}[\text{Mat}_{n,2n}]_q$.

Consider the elements of the $U_q \mathfrak{sl}_{2n}$-module $\mathbb{C}[\text{Mat}_{n,2n}]_q \otimes \mathbb{C}[\text{Mat}_{n,2n}]_q$ given by

$$\mathcal{L} = \sum_{J \subset \{1,2,\ldots,2n\} \& \text{card}(J) = n} (-q)^{l(I,J)J} t^{\wedge n}_{\{1,2,\ldots,n\} J} \otimes t^{\wedge n}_{\{n+1,2n\} J^c},$$

$$\mathcal{L} = \sum_{J \subset \{1,2,\ldots,2n\} \& \text{card}(J) = n} (-q)^{-l(I,J)J^c} t^{\wedge n}_{\{n+1,2n\} J^c} \otimes t^{\wedge n}_{\{1,2,\ldots,n\} J}.$$ 

Here $J^c$ is the complement to $J$ and $l(I,J) = \text{card}\{(i,j) \in I \times J | i > j\}$.

Proposition 6.3 $\mathcal{L}$ and $\mathcal{L}$ are $U_q \mathfrak{sl}_{2n}$-invariants.

Proof is expounded for $\mathcal{L}$. In the case of $\mathcal{L}$, similar arguments are applicable.

Recall a $q$-analog for the Laplace formula of splitting the quantum determinant of the $2n \times 2n$-matrix $t = (t_{ij})$ with respect to the upper $n$ lines:

$$\text{det}_q t = \sum_{J \subset \{1,2,\ldots,2n\} \& \text{card}(J) = n} (-q)^{l(I,J)J} t^{\wedge n}_{\{1,2,\ldots,n\} J} t^{\wedge n}_{\{n+1,2n\} J^c} = \sum_{J \subset \{1,2,\ldots,2n\} \& \text{card}(J) = n} (-q)^{-l(I,J^c)J^c} t^{\wedge n}_{\{n+1,2n\} J^c} t^{\wedge n}_{\{1,2,\ldots,n\} J}.$$ 

Our claim follows from Lemma 6.2 the relation $m \mathcal{L} = \text{det}_q t$ and $U_q \mathfrak{sl}_{2n}$-invariance of the quantum determinant. \hfill $\square$
Note that, in view of Remark 6.1, one has $L, \xi \in \mathbb{C}[X]_q \otimes \mathbb{C}[\Xi]_q$.

Introduce, firstly, a $U_q\mathfrak{sl}_{2n}$-module of kernels $D(\Xi \times \Xi)'_q$, whose elements are formal series with coefficients from $\mathbb{C}[\text{Mat}_{nq} \rightarrow \mathbb{C}[\text{Mat}_{n}]_{qi} \otimes \mathbb{C}[\Xi]_{q,\xi}$, and, secondly, a $U_q\mathfrak{sl}_{2n}$-module of kernels $D(X \otimes \Xi)'_q$, whose elements are finite sums of the form

$$\sum_{(i,j) \notin (-N) \times (-N)} (t^i t^j \otimes 1) f_{ij}, \quad f_{ij} \in D(\Xi \times \Xi)'_q$$

(cf. (5.4)). Of course, $D(\Xi \times \Xi)'_q$ is a $\text{Pol}(\text{Mat}_{n})_q \otimes \mathbb{C}[\Xi]_{q,\xi}$-bimodule, and $D(X \otimes \Xi)'_q$ is a $\mathbb{C}[X]_{q,\xi} \otimes \mathbb{C}[\Xi]_{q,\xi}$-bimodule.

The kernel $L \in \mathbb{C}[X]_q^{\op} \otimes \mathbb{C}[\Xi]_q$ can be written in the form

$$L = (-q)^{-n^2} \cdot \left(1 + \sum_{J \notin \{1,2,\ldots,n\}} (-q)^{(J,J')} t_{(1,2,\ldots,n)}^{J} t_{(n+1,n+2,\ldots,2n)}^{J'} ight) \cdot (t \otimes t^*) .$$

Note that $t_{(1,2,\ldots,n)}^{J} t_{(n+1,n+2,\ldots,2n)}^{J'} \in \mathbb{C}[\text{Mat}_{n}]_q$, see (5.3). This allows one to write down explicitly such element $L^{-n}$ of the space of generalized kernels $D(X \otimes \Xi)'_q$ that $L^{-n} \cdot L^{-n} = L^{-n} \cdot L^{n} = 1$, where $\cdot$ stands for the (left and right) actions of $L^{-n}$ on the element $L^{-n}$ of the bimodule $D(X \times \Xi)'_q$.

A similar construction produces also a $U_q\mathfrak{sl}_{2n}$-invariant generalized kernel $\xi^{-n}$.

Note that $L^{-n} = \sum_i x_i$ is a formal series with $x_i \in \mathbb{C}[\text{Mat}_{n}]_{qi} \otimes \mathbb{C}[\Xi]_{q,\xi}$, $i \in \mathbb{Z}_+$, and the terms of the formal series $\xi^{-n} = \sum_j y_j$ are such that $y_j \in \mathbb{C}[\text{Mat}_{n}]_{q,-j} \otimes \mathbb{C}[\Xi]_{q,\xi}$. This allows one to define the ‘product’ $\xi^{-n} L^{-n}$ as a double series $\sum_{i,j} y_j x_i$ which is thus an element of the module of generalized kernels $D(X \otimes \Xi)'_q$. Clearly, one has $\xi^{-n} \cdot (\xi^{-n} L^{-n}) \cdot L^{n} = 1$ in $D(X \times \Xi)'_q$, and this property determines uniquely the generalized kernel $\xi^{-n} L^{-n}$. Furthermore, the above uniqueness allows one to verify invariance of the generalized kernel $\xi^{-n} L^{-n}$. Of course the argument should apply the invariance of $L, \xi$.

Consider the Poisson kernel $P \in D(\Xi \times \Xi)'_q$ for the matrix ball by demanding the following properties:

i) up to a constant multiplier, the Poisson kernel is just $(1 \otimes tt^*)^n \xi^{-n} L^{-n}$, that is

$$P = \text{const}(q,n)(1 \otimes tt^*)^n \xi^{-n} L^{-n};$$

ii) the integral operator with kernel $P$ takes $1 \in \mathbb{C}[S(\Xi)]_q$ to $1 \in D(\Xi)'_q$.

Lemma 6.4. The integral operator $\mathbb{C}[S(\Xi)]_q \rightarrow D(\Xi)'_q$ with kernel $(1 \otimes tt^*)^n \xi^{-n} L^{-n}$ is a morphism of $U_q\mathfrak{sl}_{2n}$-modules.

Proof. It follows from the existence of an invariant integral $\eta : \mathbb{C}[\Xi]_{q}^{(-n,-n)} \rightarrow \mathbb{C}$ and the invariance of $\xi^{-n} L^{-n}$ that the integral operator $\mathbb{C}[S(\Xi)]_q \rightarrow D(\Xi)'_q$ with kernel $\xi^{-n} L^{-n}$ is a morphism of $U_q\mathfrak{sl}_{2n}$-modules. Now it remains to move the multiplier $(1 \otimes t^*-nt^-)$ from $\xi^{-n} L^{-n}$ to the left and to apply (5.6). □
Remark 6.5 Since the integral operator $\mathbb{C}[S(\mathbb{D})]_{q} \rightarrow \mathcal{D}(\mathbb{D})'_{q}$ with kernel $(1\otimes tt^*)^n \mathcal{L}^{-n}$ is a morphism of $U_q\mathfrak{sl}_{2n}$-modules, the image of $1 \in \mathbb{C}[S(\mathbb{D})]_{q}$ is a $U_q\mathfrak{sl}_{2n}$-invariant element of $\mathcal{D}(\mathbb{D})'_{q}$, that is just a constant. This proves the existence of the Poisson kernel $P$.

Example 6.6 Let us illustrate the Poisson kernel $P$ determined above in the simplest case $n = 1$. The considered invariant kernels were obtained in the early paper [29]. The elements

$$
\mathcal{L} = t_{11} \otimes t_{22} - qt_{12} \otimes t_{21}, \quad \mathcal{L} = -q^{-1}t_{21} \otimes t_{12} + t_{22} \otimes t_{11}
$$

of the algebra $\mathbb{C}[X]_{q,x} \otimes \mathbb{C}[\Xi]_{q,\xi}$ are $U_q\mathfrak{sl}_2$-invariant kernels. We present below an easy computation, which uses, for the sake of brevity, the notation

$$z = qt_{12} t_{11}, \quad z^* = t_{22} t_{21}^{-1},$$

instead of mentioning explicitly the embeddings $\mathcal{I}, J$. One has:

$$
\mathcal{L} = (1 - z \otimes z^*)(-qt_{12} \otimes t_{21}), \quad \mathcal{L} = (-q^{-1}t_{21} \otimes t_{12})(1 - q^2 z^* \otimes z),
$$

and, as $t = t_{12}$, $t^* = -qt_{21},$

$$
\mathcal{L} = (1 - z \otimes z^*)(t \otimes t^*), \quad \mathcal{L} = (q^{-2}t^* \otimes t)(1 - q^2 z^* \otimes z).
$$

Hence,

$$
\mathcal{L}^{-1} \mathcal{L}^{-1} = q^2(1 \otimes t^{-1} t^{*^{-1}})(1 - z^* \otimes z)^{-1}((1 - z^* z) \otimes 1)(1 - z \otimes z^*)^{-1}.
$$

Omit $\otimes$ and replace in the second tensor multiplier $z$ by $\zeta$ and $z^*$ by $\zeta^*$ (which is standard in function theory) to obtain

$$P = \text{const}(q)(1 - z^* \zeta)^{-1}(1 - z^* z)(1 - z \zeta^*)^{-1}.$$

What remains now is to find const$(q)$, or, to be more precise, to prove that const$(q) = 1$. In fact, the integral operator with kernel $(1 - z^* \zeta)^{-1}(1 - z^* z)(1 - z \zeta^*)^{-1}$ takes 1 to 1. This is because $\zeta^* = \zeta^{-1}$, and integration of the product of the series in $\zeta$ produces the constant term: $\sum_{k=0}^{\infty} z^k(1 - zz^*) z^{*k} = 1$.

Note that the Poisson kernel is a formal series $P = \sum_{j,k=0}^{\infty} p_{jk}$, with $p_{jk} \in \mathbb{C}[\text{Mat}_{n}]_{q} - \mathbb{C}[\text{Mat}_{n}]_{q,j} \otimes \mathbb{C}[S(\mathbb{D})]_{q}$. In the sequel we will omit $\otimes$ and replace in the second tensor multiplier $z$ by $\zeta$ and $z^*$ by $\zeta^*$ (which is standard in function theory).

Lemma 6.7 The following relation is valid:

$$
p_{11} = \text{const}(q, n) \sum_{a,b,a,\alpha,\beta=1}^{n} \left( \frac{1 - q^{-2n}}{1 - q^{-2}} q^{2(2n-a-\alpha)} \zeta^a (\zeta^\beta)^* - \delta_{ab} \delta^{a\alpha} \right) (z^a)^* z^\beta, \quad (6.1)
$$

with const$(q, n) \neq 0$. 

\[14\]
Proof. In the algebra of kernels one has

\[ L = \left( 1 - \sum_{a,\alpha=1}^{n} z_a^\alpha (\zeta_a^\alpha)^* + \ldots \right) t^\tau, \quad (6.2) \]

\[ \overline{L} = q^{-2n^2} t^\ast \tau \left( 1 - q^2 \sum_{a,\alpha=1}^{n} q^{2(2n-a-\alpha)} (z_a^\alpha)^* (\zeta_a^\alpha) + \ldots \right), \quad (6.3) \]

which is easily deducible from (5.3), (5.1), and the fact that \( \mathcal{I} \) is a homomorphism of \(*\)-algebras. Also, it is very well visible from (5.2) that

\[ y = (tt^\ast)^{-1} = 1 - \sum_{a,\alpha=1}^{n} (z_a^\alpha)^* z_a^\alpha + \ldots. \quad (6.4) \]

Here three dots replace the terms whose degree is above two, and the following abbreviated notation is implicit:

\[ t = t \otimes 1, \quad \tau = 1 \otimes \tau, \quad z_a^\alpha = z_a^\alpha \otimes 1, \quad \zeta_a^\alpha = 1 \otimes \zeta_a^\alpha, \]

\[ t^\ast = t^\ast \otimes 1, \quad \tau^\ast = 1 \otimes \tau^\ast, \quad (z_a^\alpha)^* = (z_a^\alpha)^* \otimes 1, \quad (\zeta_a^\alpha)^* = 1 \otimes (\zeta_a^\alpha)^*. \]

Apply (6.2) - (6.4), together with the commutation relations (see also (5.5))

\[ t^\ast \tau \left( \sum_{a,\alpha=1}^{n} q^{2(2n-a-\alpha)} (z_a^\alpha)^* \zeta_a^\alpha \right) = q^{-2} \left( \sum_{a,\alpha=1}^{n} q^{2(2n-a-\alpha)} (z_a^\alpha)^* \zeta_a^\alpha \right) t^\ast \tau \]

\[ t^\tau \left( \sum_{a,\alpha=1}^{n} z_a^\alpha (\zeta_a^\alpha)^* \right) = q^{2} \left( \sum_{a,\alpha=1}^{n} z_a^\alpha (\zeta_a^\alpha)^* \right) t^\tau, \]

to obtain:

\[ \overline{L}^{-n} L^{-n} = \prod_{j=1}^{n} \left( 1 - q^{2j} \sum_{a,\alpha=1}^{n} q^{2(2n-a-\alpha)} (z_a^\alpha)^* \zeta_a^\alpha + \ldots \right)^{-1} \cdot q^{2n^3} (\tau^\ast \tau)^{-n} (tt^\ast)^{-n} \prod_{j=0}^{n-1} \left( 1 - q^{2j} \sum_{a,\alpha=1}^{n} z_a^\alpha (\zeta_a^\alpha)^* + \ldots \right)^{-1}. \]

Hence

\[ P = \text{const}(q, n) \prod_{j=0}^{n-1} \left( 1 - q^{2j} \sum_{a,\alpha=1}^{n} q^{2(2n-a-\alpha)} (z_a^\alpha)^* \zeta_a^\alpha + \ldots \right)^{-1} \cdot \prod_{j=0}^{n-1} \left( 1 - q^{2j} \sum_{a,\alpha=1}^{n} z_a^\alpha (\zeta_a^\alpha)^* + \ldots \right)^{-1} \cdot \left( 1 - \sum_{a,\alpha=1}^{n} (z_a^\alpha)^* z_a^\alpha + \ldots \right)^{n} \prod_{j=0}^{n-1} \left( 1 - q^{2j} \sum_{a,\alpha=1}^{n} z_a^\alpha (\zeta_a^\alpha)^* + \ldots \right)^{-1}, \quad (6.5) \]

where three dots inside every parentheses denotes the contribution of the terms whose degree is above two, and the multipliers in the products are written in order of decrease of the index \( j \) from left to right.

Now (6.1) follows from (6.5). □
Remark 6.8 A formal passage to a limit as \( q \to 1 \) in (6.1) leads to

\[
p_{11} = \text{const}(n) \sum_{a,b,\alpha,\beta=1}^{n} (n \zeta_{a}^{\alpha} \zeta_{b}^{\beta} - \delta_{ab}\delta_{\alpha\beta}) \bar{z}_{a}^{z_{b}^{\beta}}.
\]

This relation is well known (with \( \text{const}(n) = n \)), see, for example, [15, p. 597], and is a consequence of (1.1).

Remark 6.9 Using the definition of \( P \), (6.5) and the definition of the integral over the Shilov boundary, one can compute \( \text{const}(q, n) \) explicitly. But we do not need this value on the way to Hua equations.

7 Deducing the Hua equations

Now we are about to produce a quantum analog of (1.3).

It follows from Lemma 6.7 and the definition of multiplication in the algebra of kernels that

\[
\left. \frac{\partial^2 P}{\partial z_{b}^{\beta} \partial (z_{a}^{\alpha})^*} \right|_{z=0} = \text{const}(q, n) \cdot \left( \frac{1 - q^{-2n}}{1 - q^{-2}} q^{2(2n-a-\alpha)} \zeta_{a}^{\alpha} (\zeta_{b}^{\beta})^* - \delta_{ab}\delta_{\alpha\beta} \right).
\]

Set here \( a = b = c \) to get

\[
\left. \frac{\partial^2 P}{\partial z_{c}^{\beta} \partial (z_{c}^{\alpha})^*} \right|_{z=0} = \text{const}(q, n) \cdot \left( \frac{1 - q^{-2n}}{1 - q^{-2}} q^{2(2n-c-\alpha)} \zeta_{c}^{\alpha} (\zeta_{c}^{\beta})^* - \delta_{\alpha\beta} \right).
\]

On the other hand, the generators of the function algebra on the Shilov boundary are subject to the relation

\[
\sum_{c=1}^{n} \zeta_{c}^{\alpha} (\zeta_{c}^{\beta})^* = q^{-2n+\alpha+\beta}\delta_{\alpha\beta}, \quad \alpha, \beta = 1, 2, \ldots, n,
\]

see (2.2). Hence

\[
\frac{1}{\text{const}(q, n)} \sum_{c=1}^{n} q^{2c} \left. \frac{\partial^2 P}{\partial z_{c}^{\beta} \partial (z_{c}^{\alpha})^*} \right|_{z=0}
= \frac{1 - q^{-2n}}{1 - q^{-2}} q^{2(2n-a-\alpha)} \sum_{c=1}^{n} \zeta_{c}^{\alpha} (\zeta_{c}^{\beta})^* - q^{2} \frac{1 - q^{2n}}{1 - q^{-2}} \delta_{\alpha\beta} =
= \frac{1 - q^{-2n}}{1 - q^{-2}} q^{2(2n-a-\alpha)} q^{-2n+\alpha+\beta}\delta_{\alpha\beta} - q^{2} \frac{1 - q^{2n}}{1 - q^{-2}} \delta_{\alpha\beta} = 0,
\]

so that the following statement is valid.

Lemma 7.1 If \( u \in \mathcal{D}(\mathbb{D})' \) is a Poisson integral on the quantum \( n \times n \)-matrix ball, then

\[
\sum_{c=1}^{n} q^{2c} \left. \frac{\partial^2 u}{\partial z_{c}^{\beta} \partial (z_{c}^{\alpha})^*} \right|_{z=0} = 0
\]

for all \( \alpha, \beta = 1, 2, \ldots, n \).
Since the subspace of Poisson integrals
\[ u = \int_{S^2} P(z, \zeta) f(\zeta) d\nu(\zeta), \quad f \in \mathbb{C}[S(\mathbb{D})], \]
is a $U_q\mathfrak{sl}_{2n}$-submodule, the above lemma implies Theorem 3.1.

It is known [9], that in the classical case $q = 1$ the Poisson kernel $P$ is a solution of one more equation system
\[ \sum_{\gamma=1}^{n} \frac{\partial^2 u(g \cdot z)}{\partial z^\gamma_b \partial z^\gamma_a} \bigg|_{z=0} = 0, \quad g \in \text{SU}_{n,n}, \quad a, b \in \{1, 2, \ldots, n\}. \]

An argument similar to the above allows one to obtain a $q$-analog of this result.

**Proposition 7.2** If $u \in \mathcal{D}(\mathbb{D})'$ is a Poisson integral on the quantum $n \times n$-matrix ball, then
\[ \sum_{\gamma=1}^{n} q^{2\gamma} \frac{\partial^2 (\xi u)}{\partial z_a^\gamma \partial (z_b^\gamma)^*} \bigg|_{z=0} = 0 \]
for all $\xi \in U_q\mathfrak{sl}_{2n}, \ a, b = 1, 2, \ldots, n$. 

### 8 Addendum. Hint to a more general case

Turn from the special case of $n \times n$-matrix ball to a more general case bounded symmetric domain of tube type. We intend to introduce the Hua operator, which can be used in order to rewrite the Hua equations in a more habitual form, see [15, p. 593].

Let $\mathfrak{g}$ be a simple complex Lie algebra, \((a_{ij})_{i,j=1,...,l}\) the associated Cartan matrix. We refer to the well known (see [14]) description of the universal enveloping algebra $U\mathfrak{g}$ in terms of its generators $e_i, f_i, h_i, i = 1, \ldots, l$, and the standard relations. Consider also the linear span $\mathfrak{h}$ of the set \(\{h_i, i = 1, \ldots, l\}\) (a Cartan subalgebra), and the simple roots \(\{\alpha_i \in \mathfrak{h}^* | i = 1, \ldots, l\}\) given by $\alpha_i(h_j) = a_{ji}$. Let $\delta$ be the maximal root, $\delta = \sum_{i=1}^{l} c_i \alpha_i$.

Assume that it is possible to choose $l_0 \in \{1, \ldots, l\}$ so that $c_{l_0} = 1$. Fix an element $h_0 \in \mathfrak{h}$ with the following properties:

$\alpha_i(h_0) = 0, \quad i \neq l_0; \quad \alpha_{l_0}(h_0) = 2$.

In this case the Lie algebra $\mathfrak{g}$ is equipped with the $\mathbb{Z}$-grading as follows:
\[ \mathfrak{g} = \mathfrak{g}_{-1} \oplus \mathfrak{g}_0 \oplus \mathfrak{g}_{+1}, \quad \mathfrak{g}_j = \{\xi \in \mathfrak{g} | [h_0, \xi] = 2j\xi\} \tag{8.1} \]
(that is, $\mathfrak{g}_i = \{0\}$ for all $i$ with $|i| > 1$).

Denote by $\mathfrak{k} \subset \mathfrak{g}$ the Lie subalgebra, generated by \[ e_i, f_i, \quad i \neq l_0; \quad h_i, \quad i = 1, \ldots, l. \]

If (8.1) is true then $\mathfrak{g}_0 = \mathfrak{k}$, and the pair $(\mathfrak{g}, \mathfrak{k})$ is called the Hermitian symmetric pair. In what follows, we obey the conventions of the theory of Hermitian symmetric spaces, where it is custom to use the notation $\mathfrak{p}^\pm$ instead of $\mathfrak{g}_{\pm 1}$ as in (8.1).
Harish-Chandra introduced a standard realization of an irreducible bounded symmetric domain $D$, considered up to biholomorphic isomorphisms, as a unit ball in the normed space $p^-$. Let $G$ be the simply connected complex linear algebraic group with $\text{Lie}(G) = \mathfrak{g}$, and $K \subset G$ such connected linear algebraic subgroup that $\text{Lie}(K) = \mathfrak{k}$. In this context one has the well known Harish-Chandra embedding

$$i : K \backslash G \hookrightarrow p^-.$$ 

Let $W$ be the Weyl group of the root system $\mathcal{R}$ of $\mathfrak{g}$, and $w_0 \in W$ the longest element. The irreducible bounded symmetric domain $D$ associated to the pair $(\mathfrak{g}, \mathfrak{k})$, is a tube type domain if and only if $w_0 = -w_0 w_0$. Let $U_q \mathfrak{g}$ be the quantum universal enveloping algebra of $\mathfrak{g}$. Recall that it is a Hopf algebra and can be described in terms of its generators $E_i, F_i, K_i^{\pm 1}$, $i = 1, \ldots, l$, and the standard Drinfeld-Jimbo relations.

Introduce quantum analogs for invariant differential operators to be used to produce the Hua operator.

Let $V$ be a finite dimensional weight $U_q \mathfrak{g}$-module. In an obvious way, $V \otimes_{U_q \mathfrak{k}} U_q \mathfrak{g}$ is equipped with a structure of right $U_q \mathfrak{g}$-module. It is easy to see that in the category of left $U_q \mathfrak{g}$-modules

$$\text{Hom}_{U_q \mathfrak{g}}(U_q \mathfrak{g}, V) \cong (V^* \otimes_{U_q \mathfrak{k}} U_q \mathfrak{g})^*,$$

$$f \mapsto \tilde{f}, \quad \tilde{f}(l \otimes \xi) = l(f(\xi)), \quad l \in V^*, \quad \xi \in U_q \mathfrak{g}.$$ 

The vector space $\text{Hom}_{U_q \mathfrak{g}}(U_q \mathfrak{g}, V)$ is a quantum analog for the space of sections of a homogeneous vector bundle on the homogeneous space $K \backslash G$. Suppose we are given two finite dimensional weight $U_q \mathfrak{g}$-modules $V_1, V_2$ and a morphism of right $U_q \mathfrak{g}$-modules

$$A : V_2^* \otimes_{U_q \mathfrak{k}} U_q \mathfrak{g} \to V_1^* \otimes_{U_q \mathfrak{k}} U_q \mathfrak{g}.$$ 

Associate to the latter morphism the adjoint linear map

$$A^* : \text{Hom}_{U_q \mathfrak{g}}(U_q \mathfrak{g}, V_1) \to \text{Hom}_{U_q \mathfrak{g}}(U_q \mathfrak{g}, V_2),$$

which is also a morphism of $U_q \mathfrak{g}$-modules. Such dual operators are treated as quantum analogs of invariant differential operators.

Thus the invariant differential operators are in one-to-one correspondence with the elements of the space

$$\text{Hom}_{U_q \mathfrak{g}}(V_2^* \otimes_{U_q \mathfrak{k}} U_q \mathfrak{g}, V_1^* \otimes_{U_q \mathfrak{k}} U_q \mathfrak{g}) \cong \text{Hom}_{U_q \mathfrak{g}}(V_2^*, V_1^* \otimes_{U_q \mathfrak{k}} U_q \mathfrak{g}),$$

$$f \mapsto \tilde{f}, \quad \tilde{f}(l) = f(l \otimes 1), \quad l \in V_2^*.$$ 

Turn to a construction of the Hua operator. Set $p^+ = U_q \mathfrak{k} E_{l_0}$, $p^- = U_q \mathfrak{k} (K_{l_0} F_{l_0})$, both are finite dimensional weight $U_q \mathfrak{k}$-modules. The morphisms of right $U_q \mathfrak{k}$-modules

$$p^+ \to \mathbb{C} \otimes_{U_q \mathfrak{k}} U_q \mathfrak{g}, \quad E_{l_0} \mapsto 1 \otimes E_{l_0},$$

$$p^- \to \mathbb{C} \otimes_{U_q \mathfrak{k}} U_q \mathfrak{g}, \quad K_{l_0} F_{l_0} \mapsto 1 \otimes K_{l_0} F_{l_0}$$

determine invariant linear differential operators

$$\text{Hom}_{U_q \mathfrak{k}}(U_q \mathfrak{g}, \mathbb{C}) \to \text{Hom}_{U_q \mathfrak{k}}(U_q \mathfrak{g}, p^\pm).$$
Recall that $U_q\mathfrak{t}$-modules form a tensor category, and that the comultiplication $\Delta : U_q\mathfrak{g} \to U_q\mathfrak{g} \otimes U_q\mathfrak{g}$ is a morphism of this category.

Consider the morphisms of $U_q\mathfrak{g}$-modules

$$
\text{Hom}_{U_q\mathfrak{g}}(U_q\mathfrak{g}, \mathbb{C}) \to \text{Hom}_{U_q\mathfrak{g}}(U_q\mathfrak{g} \otimes U_q\mathfrak{g}, p^+ \otimes p^-),
$$

$$
\text{Hom}_{U_q\mathfrak{g}}(U_q\mathfrak{g} \otimes U_q\mathfrak{g}, p^+ \otimes p^-) \to \text{Hom}_{U_q\mathfrak{g}}(U_q\mathfrak{g}, p^+ \otimes p^-).
$$

Let $\mathfrak{t}_q$ be the finite dimensional weight $U_q\mathfrak{t}$-module with the same weights and weight multiplicities as the $U\mathfrak{t}$-module $\mathfrak{t}$. There exists a unique $U_q\mathfrak{t}$-submodule $\mathcal{H}_q \subset p^+ \otimes p^-$ such that $(p^+ \otimes p^-)/\mathcal{H}_q \approx \mathfrak{t}_q$ (because a similar fact is well known in the classical case $q = 1$, see [2, Proposition 4.2]). Fix an onto morphism $p^+ \otimes p^- \to \mathfrak{t}_q$ and consider the associated invariant ‘formal’ differential operator

$$
\text{Hom}_{U_q\mathfrak{t}}(U_q\mathfrak{g}, p^+ \otimes p^-) \to \text{Hom}_{U_q\mathfrak{t}}(U_q\mathfrak{g}, \mathfrak{t}_q).
$$

Denote by $D_q$ the composition of the maps (8.2), (8.3), and (8.4). By definition, $D_q$ is an invariant differential operator.

Recall the standard definitions of quantum analogs for the algebras of regular functions on the group $G$ and on the homogeneous space $K\backslash G$. Denote by $\mathbb{C}[G]_q \subset (U_q\mathfrak{g})^*$ the Hopf algebra of all matrix elements of weight finite dimensional of $U_q\mathfrak{g}$. $\mathbb{C}[G]_q$ is equipped with a structure of $U_q^{\text{op}}\mathfrak{g} \otimes U_q\mathfrak{g}$-module algebra via quantum analogs of the standard right and left regular actions $(\xi' \otimes \xi'') f = L_{\text{reg}}(\xi') R_{\text{reg}}(\xi'') f$, where

$$
L_{\text{reg}}(\xi') f)(\eta) = f(\xi' \eta), \quad R_{\text{reg}}(\xi'') f)(\eta) = f(\eta \xi''), \quad \xi', \xi', \eta \in U_q\mathfrak{g}, \quad f \in \mathbb{C}[G]_q.
$$

($U_q^{\text{op}}\mathfrak{g}$ is the Hopf algebra with the opposite multiplication). $\mathbb{C}[G]_q$ is called the algebra of regular functions on the quantum group $G$.

Introduce the notation

$$
\mathbb{C}[K\backslash G]_q = \{ \xi \in \mathbb{C}[G]_q | L_{\text{reg}}(\eta)\xi = 0, \quad \eta \in U_q\mathfrak{t} \}.
$$

This Hopf subalgebra is a quantum analog for the algebra of regular functions on the homogeneous space $K\backslash G$. It is easy to prove that $\mathbb{C}[K\backslash G]_q \subset \text{Hom}_{U_q\mathfrak{t}}(U_q\mathfrak{g}, \mathbb{C})$, so one can consider the restriction of $D_q$ onto $\mathbb{C}[K\backslash G]_q$.

One can consider a localization $\mathbb{C}[K\backslash G]_{q,x}$ of the algebra $\mathbb{C}[K\backslash G]_q$ with respect to the Ore set $x^{\mathbb{Z}^+}$. It can be proved that the extension of $D_q$ up to $\mathbb{C}[K\backslash G]_{q,x}$ is well defined. Pass from $\mathbb{C}[K\backslash G]_{q,x}$ to $\text{Pol}(p^-)_q$ (via the Harish-Chandra embedding $\mathcal{I}$, see Section 5 for the special case) and $D(\mathcal{D})'_q$ to get a $q$-analogue for the Hua operator.
