NNLO Calculation of Two-Nucleon Scattering in EFT for a Two Yukawa Toy Model

Gautam Rupak and Noam Shoresh

Department of Physics, University of Washington, Seattle, WA 98195

Abstract

The effective field theory (EFT) for a toy model of nucleons interacting via a short range and a long range Yukawa potential is presented. The scattering amplitude in the $^1S_0$ channel is calculated up to NNLO using KSW power counting scheme. A particular expansion of the amplitude about the pole at low (imaginary) momentum is used to derive matching conditions on the EFT couplings. In addition, after imposing constraints from a Renormalization Group flow analysis, there are no new free parameter in the amplitude at NNLO. Comparing the NNLO phase shifts to the full model we show that the EFT expansion is converging.

I. INTRODUCTION

Effective field theory (EFT) can be a very useful tool in the study of nuclear physics at low energies [1]- [25]. Most importantly, it provides a perturbative description of physical processes at momentum $p$ well below a certain cutoff $\Lambda$. If fields for the lighter degrees of freedom are included explicitly, and the effects of the heavier particles are encoded in a derivative expansion of local operators, one expects effects of the high-energy physics to be suppressed by powers of $p/\Lambda$. Furthermore, a perturbative expansion allows a systematic estimation of errors at any order of the perturbation.

The contact terms in the Lagrangian that replace high-energy, short-range interactions, have dimensionful couplings. The mass scales that enter these couplings originate in the microscopic theory, and they are usually assumed to be “natural”, i.e. of $O(\Lambda)$. In that case, the derivative expansion of contact terms in the Lagrangian is an expansion in powers of $p/\Lambda$.

However, constructing an EFT for nucleons requires special care. The reason is the appearance of other length scales, in particular the $^1S_0$ scattering length, $a$, which is much larger than the range of the interactions ($a \sim 1/8 \text{ MeV} \gg 1/m_{\pi}, 1/m_{\rho}$). In this case the coupling constants need not follow the natural scaling of $1/\Lambda$, but rather may make up the dimensions by factors of $a$.

To understand the problem better, one first considers nucleons interacting through a single short range potential [2]. In the lack of other “light” scales in the problem, one expects the scattering amplitude at low energies to be a simple Taylor expansion in $p/\Lambda$.
of the exact amplitude. The scattering amplitude is related to the phase shift in the $^1S_0$ channel through

$$A = \frac{4\pi}{M} \frac{1}{p \cot(\delta) - ip}, \quad (1.1)$$

where $p = \sqrt{ME}$ is the momentum of each nucleon in the center of mass coordinates and $\delta$ is the $^1S_0$ phase shift. The problem can be analyzed with the tools of quantum mechanics (which applies to the non-relativistic, heavy nucleons) where one writes what is known as the Effective Range Expansion (ERE):

$$p \cot(\delta) = -\frac{1}{a} + \frac{1}{2} \sum_{n=0}^{\infty} r_n p^{2(n+1)}. \quad (1.2)$$

$a$ is the scattering length and can be arbitrarily large, while the other length scales $r_0, r_1, \ldots$ are assumed to all have natural sizes, $r_n \sim 1/\Lambda^{2(n+1)}$. $p$ is taken to be small compared to $\Lambda$, but not compared to $1/a \ll \Lambda$.

Substituting Eq. (1.2) in Eq. (1.1), it can be seen that there is a pole in the amplitude at $p \approx i/a$, which sets a small radius of convergence for the naive Taylor expansion about $p = 0$. This explains the breakdown of the simple approach at momenta $p \sim 1/a$, and also suggests the solution - the EFT must be constructed in such a way as to include the pole in the amplitude at all orders.

In [2] the following expansion of the amplitude was presented:

$$A = -\frac{4\pi}{M} \frac{1}{(1/a + ip)} \left[ 1 + \frac{r_0/2}{(1/a + ip)} p^2 + \frac{(r_0/2)^2}{(1/a + ip)^2} p^4 + \frac{(r_1/2)}{(1/a + ip)} p^4 + \cdots \right]. \quad (1.3)$$

In this paper we examine a different expansion [30] in which the exact pole in the amplitude appears explicitly. We rewrite (1.2) as

$$p \cot(\delta) = -\gamma + \frac{1}{2} \sum_{n=0}^{\infty} s_n \left( \gamma^2 \right)^{n+1}. \quad (1.4)$$

where $i\gamma$ is the pole in the amplitude. We expand the amplitude in $p/\Lambda$ and $\gamma/\Lambda$. The coefficients $s_n$ and $r_n$ are the same at leading order. Comparing the expansions Eqns. (1.2) and (1.4), one can solve perturbatively for the relation between the coefficients $r_n$ and $s_n$. The first two terms are

$$-\frac{1}{a} = -\gamma + \frac{1}{2} \gamma^2 s_0 + O(\gamma^4)$$
$$r_0 = s_0 + \gamma^2 s_1 + O(\gamma^4).$$

Note that the difference between $\gamma$ and $1/a$ enters at NNLO, whereas the difference between $s_0$ and $r_0$ is only important at higher orders.

Combining Eqns. (1.4) and (1.1) gives

$$A = \frac{4\pi}{M} \frac{1}{\gamma + ip} \left[ 1 + \frac{s_0 p^2 + \gamma^2}{2 \gamma + ip} + \left( \frac{s_0}{2} \frac{p^2 + \gamma^2}{(\gamma + ip)^2} \right) \right].$$
The EFT for nucleons with explicit pions has already been used [2] to calculate the $^1S_0$ phase shifts at leading and next-to-leading orders (LO and NLO). A next-to-next-to-leading order (NNLO) calculation is needed primarily to check the convergence of the EFT expansion. More generally it serves as a probe for better understanding of different aspects of the theory - like the appropriate fitting procedure and the role of the renormalization group flow.

The scattering amplitude at NNLO gets contributions from instantaneous pion exchanges ("potential pions"), as in NLO, and also from retardation effects in pion exchange ("radiation pions") and relativistic corrections. The relativistic corrections are very small compared to the potential pion contribution even at high momentum. The radiation pion effects have been found to be highly suppressed due to Wigner’s SU(4) spin-isospin symmetry in the large scattering length limit in the singlet and triplet channel of N-N scattering [29].

In this paper we analyze a toy model, with some realistic features, but without retardation pion effects and relativistic corrections. The EFT for nucleons using the KSW power counting scheme is not completely understood yet, and it is beneficial to probe it further with an NNLO calculation in a “cleaner” setup. It should be noted that the EFT amplitude calculated for this toy model is the same as the potential pions contribution to the one appropriate for the real $^1S_0$ case.

We calculate the $^1S_0$ phase shift up to NNLO in a two-Yukawa toy model which is presented in Section II, with the corresponding effective Lagrangian described in Section III. A brief review of the KSW power counting is presented in Section IV. Section V includes the calculation in the effective theory without pions, whereas the NLO and NNLO scattering amplitudes in the theory with pions are calculated in sections VI and VII respectively. In Subsection VIII A we derive constraints on some of the EFT couplings. The renormalization group flow is discussed in Subsection VIII B, where the rest of the couplings at NNLO are fixed. The comparison with the two-Yukawa phase shifts is presented in Section IX, followed by summary and conclusions in Section X.

II. THE TOY MODEL

In this section a theory is described which can be solved exactly. Later, the low energy behavior of this theory is modeled by an EFT.

We consider non-relativistic nucleons interacting via two instantaneous Yukawa potentials:

$$V(r) = -g_\pi \frac{e^{-m_\pi r}}{4\pi r} - g_\rho \frac{e^{-m_\rho r}}{4\pi r}$$  (2.1)
(r is the distance between the nucleons). This model has several appealing features. It is complex enough in the sense that it involves long range and short range interactions as in the real world. In addition, the Yukawa potentials describe the instantaneous exchange of the $\pi$ and $\rho$ mesons (without the complications of retardation effects [29]).

The realistic $^1S_0$ one pion exchange amplitude (here given in momentum space) is

$$\left(-\frac{g_\pi^2}{2f_\pi^2}\right)\frac{p^2}{p^2 + m_\pi^2} = -\frac{g_A^2}{2f_\pi^2} + \frac{g_A^2}{2f_\pi^2} \frac{m_\pi^2}{p^2 + m_\pi^2},$$

(2.2)

where the first term is a contact interaction, and the second is the Yukawa part. The contact interaction is not included in the toy model. $g_\pi$ is chosen to reproduce the Yukawa part. Comparing Eq. (2.2) and Eq. (2.1), we set

$$g_\pi = \frac{g_A^2 m_\pi^2}{2f_\pi^2}.$$  

We take the nucleons mass to be $M = 940$ MeV, as well as $m_\pi = 140$ MeV, $m_\rho = 770$ MeV, $f_\pi = 132$ MeV and $g_A = 1.25$. $g_\rho$ is tuned to give a large scattering length ($a \sim -24$ fm) by numerically solving the Schroedinger equation with this potential. The toy model is used in generating all the $^1S_0$ phase shifts.

III. THE EFFECTIVE LAGRANGIAN

The effective Lagrangian for the toy model is described in this section. It is appropriate for center of mass energies much smaller than $m_\rho$. The effects of the short range force are reproduced in the EFT by contact interactions. As noted in [3], it is convenient to separate the effective Lagrangian in terms of the number of nucleon fields present:

$$\mathcal{L} = \mathcal{L}_1 + \mathcal{L}_2 + ...,$$

where $\mathcal{L}_n$ describes the propagation or scattering of $n$ nucleons. $\mathcal{L}_1$ is the usual kinetic energy term [3,26]

$$\mathcal{L}_1 = N^\dagger (i\partial_0 + \vec{\nabla}^2/2M)N,$$

(3.1)

where the isodoublet field $N$ represents the nucleons:

$$N = \begin{pmatrix} p \\ n \end{pmatrix}$$

Next, we write $\mathcal{L}_2^{(1S_0)}$, the part of $\mathcal{L}_2$ that has non-vanishing matrix elements between $^1S_0$ states. The matrices $P_k$ [3] are used to project onto the $^1S_0$ state,

$$P_k \equiv \frac{1}{\sqrt{8}} \sigma_2 \otimes \tau_2 \tau_k,$$

where the $\sigma$ matrices act on the nucleon spin space and the $\tau$ matrices act on the nucleon isospin space. The result is [2,3]:  

4
\[
\mathcal{L}^{(S_0)}_2 = - \left( \frac{\mu}{2} \right)^{4-D} (C_0 + D_2 m_\pi^2 + D_4 m_\pi^4 + \cdots) (N^T P_i N)^\dagger (N^T P_i N) \\
+ \left( \frac{\mu}{2} \right)^{4-D} \left( \frac{1}{8} C_2 + \frac{1}{8} D_1^{(2)} m_\pi^2 + \cdots \right) [(N^T P_i N)^\dagger (N^T P_i (\nabla)^2 N) + h.c] \\
+ \cdots 
\]

(summation over the repeated isospin index \( i \) is implied.)

We use dimensional regularization where the Lagrangian is given in \( D \) space-time dimensions and \( \mu/2 \) is an arbitrary mass scale introduced so that the couplings \( C_{2n} \), \( D_{2n}^{(2m)} \) have the same dimensions for any \( D \). \( C_{2n} \) are the coefficients of contact interactions containing \( 2n \) derivatives and \( D_{2n}^{(2m)} \) are coefficients of contact interactions involving \( 2m \) derivatives and \( 2(n - m) \) powers of the pion mass. We use the convention \( D_{2n} \equiv D_{2n}^{(0)} \), \( C_{2n} \equiv D_{2n}^{(2n)} \). The ellipses indicate operators with higher powers of derivatives or pion mass insertions.

For \( n > 0 \) \((m > 0)\), the couplings \( C_{2n} (D_{2n}^{(2m)}) \) multiply a linear combination of operators. These different operators differ in the way the derivatives act on the legs entering the vertex. In many cases factors of internal loop momentum \( q \) result in factors of external momentum \( p \), and there is no need to distinguish between the different parts that make up a \( C_{2n} (D_{2n}^{(2m)}) \) vertex. At NNLO the first exception to this rule is encountered. We come back to this point in Section VII B.

The interaction with the pions is described by a non-local term in the action:

\[
S_\pi = \int d^D x \, d^D y \left( N^T (x) P_i N(x) \right)^\dagger g_\pi \frac{e^{-m_\pi |x-y|}}{4\pi |x-y|} \delta(x^0 - y^0) \left( N^T (y) P_i N(y) \right) \\
= \int d^D p \, d^D p' \left( N^T (p) P_i N(p) \right)^\dagger \frac{g_\pi^2}{2f^2} \frac{m_\pi^2}{|p - p'|^2 + m_\pi^2} \left( N^T (p') P_i N(p') \right).
\]

Once the effective Lagrangian has been described, one needs a power counting scheme, i.e. a set of rules that determine the relative sizes of diagrams contributing to the scattering process.

**IV. THE KSW POWER COUNTING**

The KSW power counting scheme was introduced in [2], and is designed to incorporate the effects of an unnaturally large scattering length.

The two versions of the ERE, Eq. (1.2) and Eq. (1.4), lead to two different expansions of the amplitude: Eq. (1.3) and Eq. (1.5). Both expansions coincide in the infinite scattering length limit, but they are not identical. In the next section, the effective theory without pions is revisited, mostly to demonstrate some of the consequences of using expansion Eq. (1.5). In this section, however, we concentrate on the KSW power counting scheme which follows from either expansion.

It has been shown [1] that the leading term in expansion Eq. (1.5) is obtained by summing up the bubble chains in Fig. 1 with insertions of \( C_0 \), giving the LO amplitude:

\[
A_{-1} = \frac{-C_0}{1 + iC_0 L},
\]
where $L$ is the loop integral

$$L = \left(\frac{\mu}{2}\right)^{4-D} \int \frac{d^Dq}{(2\pi)^D} \frac{i}{\frac{E}{2} - q_0 - \frac{q^2}{2M} + i\epsilon} \frac{i}{\frac{E}{2} + q_0 - \frac{q^2}{2M} + i\epsilon}$$

$$= -iM\left(\frac{\mu}{2}\right)^{4-D} \int \frac{d^{D-1}q}{(2\pi)^{D-1}} \frac{1}{q^2 - EM - i\epsilon} = -i\frac{M}{4\pi}(X_{sub} + ip). \quad (4.1)$$

A subtraction scheme that reproduces the KSW power counting is the power divergence subtraction (PDS) scheme that was introduced in [2]. In PDS one subtracts the poles of $L$ in both $D = 4$ and $D = 3$ dimension (which gives $X_{sub} = \mu$ in Eq. (4.1)). Setting $\mu \sim p$, all the diagrams contributing to the bubble chains are rendered equal in size ($\sim 1/p$). This justifies summing up the bubble graphs at LO.

In the theory with pions, pion effects are assumed to be perturbative. From the PDS subtraction scheme follows a power counting scheme -KSW- in which:

- The expansion parameter is $Q/\Lambda$, where $p, \mu, m_\pi \sim Q$.
- $A = \sum_{n=-1}^{\infty} A_n$, $A_n \sim Q^n$.
- $C_0$, scales as $1/\mu \sim 1/Q$, and more generally the $C_{2n}, D_{2n}^{(2m)}$ scale as $1/Q^{n+1}$.

Some immediate consequences are:

- The loop integral $L$ scales like $p$ or $\mu$, i.e. $O(Q)$. Therefore, adding a $C_0$ and a loop $L$ to a diagram does not change its order since the powers of $Q$ cancel. It is now required to dress each diagram in the theory by $C_0$ to all orders. (This is diagrammatically represented by the “blob”, Fig. 2).

- When the nucleons are put on shell, nucleon propagators scale as $1/Q^2$ and loop integrals $\int dq^4$ scale as $Q^5$.

This theory should correctly describe the physics at momentum below $\Lambda \sim m_\rho/2$, which is the scale associated with the cut in the amplitude due to $\rho$ exchange. A calculation to order $Q^n$ is expected to be accurate up to an error of $\sim (Q/\Lambda)^{n+1}$.

In the last three sections, all the components of the computational framework of the EFT for nucleons have been identified: the effective Lagrangian (Feynman rules), the regularization and subtraction methods, and the power counting scheme that organizes the diagrams of the theory in a perturbative series. In the following sections we apply this formalism to the calculation of the $^1S_0$ scattering amplitude.
V. THE EFFECTIVE THEORY WITHOUT PIONS

At energies low compared to the pion mass, even the long range pion exchange is effectively point-like. Both the real N-N scattering process and the one in the two-Yukawa theory are modeled by the same EFT without pions at these energies. The theory without pions has been solved before, using expansion Eq. (1.3). However, since we use the $Q$ expansion Eq. (1.5), it is instructive to consider the effective theory without pions again. Expansion Eq. (1.3) is not well behaved near the pole, at momentum $p \sim i/a$. This is because higher orders in the expansion contain terms more singular than the leading order term. This means that the $Q$ expansion breaks down close to the pole. Expansion Eq. (1.5) avoids this problem. All terms have only a simple pole and the expansion is not expected to fail even at very low $p$.

The structure of the effective Lagrangian when pion effects are integrated out can be obtained from the Lagrangian that includes pions by dropping all the $D$ couplings, as well as the interaction part $S_\pi$. Note that this only gives the structure of the Lagrangian, but the meaning of the $C$ couplings is different in the two EFTs, and the relation between them can only be seen by comparing the theories in a region where they are both valid.

Matching the LO amplitude with expansion Eq. (1.5), we find

$$C_0 = -\frac{4\pi}{M} \left( \frac{1}{\mu - \gamma} \right).$$

At NLO, dressing the $C_2 p^2$ operators with $C_0$ bubbles yields

$$A_0 = -C_2 p^2 \left( \frac{-A_{-1}}{C_0} \right)^2 \sim \frac{p^2}{(\gamma + ip)^2}.$$

This does not have the right form to reproduce the $Q$ expansion (1.5), which predicts

$$A_0 \sim \frac{p^2 + \gamma^2}{(\gamma + ip)^2}.$$

To match to the $Q$ expansion exactly at NLO, a contact operator similar to $C_0$ is needed. This suggests that a sub-leading piece from $C_0$ is required in order to reproduce the low energy expansion. More generally, we expand the parameters in powers of $Q$ [28]:
\[ C_0 = C_{0,-1} + C_{0,0} + C_{0,1} + \cdots \]
\[ C_2 = C_{2,-2} + C_{2,1} + \cdots \]
\[ C_4 = C_{4,-3} + C_{4,2} + \cdots \]
\[ \vdots \]

where the second subscript denotes the scaling with powers of \( Q \). This theory can be solved exactly to match the ERE \[32\]. Working up to NNLO we find in the PDS scheme

\[ C_{2,-2} = \frac{M s_0}{4\pi} \frac{C^2_{0,-1}}{2} = \frac{4\pi s_0}{M} \left( \frac{1}{\mu - \gamma} \right)^2 \]
\[ C_{0,0} = \gamma^2 C_{2,-2} \]
\[ C_{4,-3} = \frac{C^2_{2,-2}}{C_{0,-1}} = -\frac{4\pi s_0^2}{M} \left( \frac{1}{\mu - \gamma} \right)^3 \]
\[ C_{2,-1} = 2\gamma^2 C_{4,-3} \]
\[ C_{0,1} = \gamma^4 C_{4,-3}. \]

(5.1)

Note that only for the leading \( C_{2n,s} \), the scaling with powers of \( \mu \) is the same as the scaling with powers of \( Q \). This demonstrates explicitly how knowledge of the running couplings may not be enough to determine the power counting of an operator. Here, it is the expansion about the exact pole that has lead to this behavior.

Expansions Eq. (1.5) and Eq. (1.3) coincide in the limit \( a \to \infty (\gamma \to 0) \). This is also demonstrated in the vanishing of the sub-leading couplings in this limit.

The couplings are given in terms of the “experimental” quantities \( \gamma, s_0, s_1, \) etc.. At LO \( C_{0,-1} \) is determined from \( \gamma \), at NLO \( C_{0,0} \) and \( C_{2,-2} \) are given in terms of \( \gamma \) and \( s_0 \), and at NNLO \( C_{0,1}, C_{2,-1}, \) and \( C_{4,-3} \) are again fixed by \( \gamma \) and \( s_0 \).

To relate the scattering amplitude to phase shifts, we expand the relation

\[ \delta = \frac{1}{2i} \ln \left( 1 + i \frac{M p}{2\pi A} \right) \]

in powers of \( Q \) \[2\] (writing \( \delta = \delta_0 + \delta_1 + \cdots \)), to get

\[ \delta_0(C_0) = \frac{1}{2i} \ln \left( 1 + i \frac{M p}{2\pi A_{-1}} \right) \]
\[ \delta_1(C_0, C_2) = \frac{M p}{4\pi} \frac{A_0}{1 + \frac{M p}{2\pi} A_{-1}} \]
\[ \delta_2(C_0, C_2, C_4) = -i \left( \frac{M p}{4\pi} \frac{A_0}{1 + \frac{M p}{2\pi} A_{-1}} \right)^2 + \frac{M p}{4\pi} \frac{A_1}{1 + \frac{M p}{2\pi} A_{-1}}. \]

(5.2)

The comparison with the exact phase shifts of the two-Yukawa model up to NNLO is shown in Fig. 3 (a). The theory describes the “data” well up to \( p \sim 50 \) MeV. To investigate the cutoff \( \Lambda \) of this theory we look at the error plots \[27\] Fig. 3 (b). We see that at \( p \sim 200 \) MeV, the errors from different orders in \( Q \) expansion become comparable. Also note that the NLO and NNLO curves are essentially the same. This happens since by matching to the expansion Eq. (1.5), recovery of the expansion Eq. (1.4) of \( p \cot \delta \) is
FIG. 3. The Effective Theory Without Pions. (a) $\delta$ (degrees) vs. $p$(MeV) (b) log-log plot of $\Delta \equiv |\cot \delta_{\text{predicted}} - \cot \delta_{\text{exact}}|$ vs. $p$(MeV). The exact phase shift is described by the solid curve. The long-dashed curves denote the LO phase shift and error, the dashed curves are the NLO results, and the dot-dashed curves describe the NNLO results.

Fig. 3 is produced using only the ERE. The EFT approach provides a broad formalism in which the pions are naturally included. The next two sections describe the calculation of the scattering amplitude to NLO and NNLO in the effective theory with pions.

VI. THE EFFECTIVE THEORY WITH PIIONS: NLO

In the theory with truly dynamical pions, the contact piece of the pion exchange can be reabsorbed in the definition of $C_{0,0}$. Hence, at NLO, there is no difference in the amplitude for this toy model and the real N-N scattering amplitude as the radiation pion effects and relativistic corrections appear at NNLO. In [2], the $^1S_0$ phase shift has already been calculated to this order. We include the calculation here for clarity.

At NLO, we need to consider the following local operators, classified here according to their $Q$ counting:

$$\mathcal{O}(Q^{-1}) : -C_{0,-1}$$

$$\mathcal{O}(Q^0) : -p^2 C_{2,-2} ; -C_{0,0} ; -m_\pi^2 D_{2,-2}$$

Only the linear combination $C_{0,0} + m_\pi^2 D_{2,-2}$ appears in the amplitude, and it is denoted by $B_{0,0}$. From this point on we adopt the convention that the second subscript is omitted from leading couplings, so that, for instance, $C_0$ stands for $C_{0,-1}$, $C_2$ is really $C_{2,-2}$, etc. Also note that at NLO, the operator $C_2 \nabla^2$ can be replaced by $C_2 p^2$. As explained in Appendix C, this is not always the case.

The diagrams contributing to the NLO amplitude are shown in Fig. 4. The amplitude is

$$\mathcal{A}_0 = \mathcal{A}_0^{(0\pi)} + \mathcal{A}_0^{(\pi)}$$
where $\mathcal{A}_0^{(0\pi)}$ includes all the diagrams with no pion exchange, and $\mathcal{A}_0^{(\pi)}$ contains all the diagrams with a single pion exchange. It is convenient to express Fig. 4(b) and Fig. 4(c) in terms of the loop integrals $P_1$ and $P_2$, so that

$$\mathcal{A}_0^{(0\pi)} = (1 + i\mathcal{A}_{-1}L)^2(-B_{0,0} - C_2p^2)$$
$$\mathcal{A}_0^{(\pi)} = \frac{g_A^2 m^2_\pi}{2f^2 4p^2} \ln(1 + \frac{4p^2}{m^2_\pi}) + 2(\mathcal{A}_{-1})P_1 + i(\mathcal{A}_{-1})^2P_2,$$

with the definitions

$$P_1 \equiv \frac{i g_A^2}{2f^2 m^2_\pi} \left( \frac{\mu}{2} \right)^{4-D} \int \frac{d^Dq}{(2\pi)^D} \frac{i}{(\frac{E}{2} + q_0 - \frac{q^2}{2M} + i\epsilon)} ^{-1 \times \frac{E}{2} - q_0 - \frac{q^2}{2M} + i\epsilon (q - p)^2 + m^2_\pi}$$
$$= \frac{g_A^2}{2f^2 m^2_\pi} \int \frac{d^{D-1}q}{(2\pi)^{D-1}} \frac{1}{q^2 - p^2 - i\epsilon (q - p)^2 + m^2_\pi}$$
$$= \frac{P_{DS}}{8\pi} \frac{g_A}{2f^2 M} \left( \text{arctan} \left( \frac{p}{m_\pi} \right) + \frac{i}{2} \ln \left( 1 + \frac{4p^2}{m^2_\pi} \right) \right),$$

and

$$P_2 \equiv \frac{i g_A^2}{2f^2 m^2_\pi} \left( \frac{\mu}{2} \right)^{8-2D} \int \frac{d^Dq}{(2\pi)^D} \frac{d^Dl}{(2\pi)^D} \frac{i}{(\frac{E}{2} + q_0 - \frac{q^2}{2M} + i\epsilon)} ^{-1 \times \frac{E}{2} - l_0 - \frac{l^2}{2M} + i\epsilon (q - p)^2 + m^2_\pi}$$
$$= -\frac{i g_A^2}{2f^2 m^2_\pi} \frac{1}{2f^2 M^2} \int \frac{d^{D-1}q}{(2\pi)^{D-1}} \frac{d^{D-1}l}{(2\pi)^{D-1}} \frac{1}{q^2 - p^2 - i\epsilon}.$$
\[ iA_{1}^{(0\pi)} = O(Q') + O(Q') + O(Q') \]

**FIG. 5.** \( A_{1}^{(0\pi)} \)

\[
PDS \to -i \frac{g_{A}^{2} M^{2}}{2 f^{2} 32 \pi^{2}} \left( -\gamma_{E} + \ln(\pi) + 1 \right) -2 \ln \left( \frac{m_{\pi}}{\mu} \right) - 2 \ln \left( 1 - i2 \frac{p}{m_{\pi}} \right) \tag{6.2}
\]

Eq. (6.2), where only the poles have been subtracted, differs from an earlier calculation of \( P_{2} \) [2] that involved finite subtractions. The calculation of \( P_{2} \) in coordinate space is presented in Appendix A.

**VII. THE EFFECTIVE THEORY WITH PIONS: NNLO**

At this order, there are insertions of three kinds of local operators, listed here according to their \( Q \) counting:

\[ O(Q^{-1}) : -C_{0} \]
\[ O(Q^{0}) : -B_{0,0} ; -p^{2} C_{2} \]
\[ O(Q^{1}) : -B_{0,1} ; -p^{2} B_{2,-1} ; -p^{4} C_{4} \]

There are 3 new couplings that enter at this order: \( B_{0,1} \equiv C_{0,1} + D_{2,-1}m_{\pi}^{2} + D_{4}m_{\pi}^{4}, B_{2,-1} \equiv C_{2,-1} + D_{4}^{(2)}m_{\pi}^{2} \) and \( C_{4} \).

The NNLO amplitude is

\[ A_{1} = A_{1}^{(0\pi)} + A_{1}^{(\pi)} + A_{1}^{(\pi\pi)} \]

**A. \( A_{1}^{(0\pi)} \)**

The diagrams in Fig. 5 are generated by two insertions of \( O(Q^{0}) \) operators or a single insertion of \( O(Q^{1}) \) operators, and give:

\[
A_{1}^{(0\pi)} = (1 + iA_{-1}L)^{2}(-C_{4}p^{4} - B_{2,-1}p^{2} - B_{0,1})
+ (1 + iA_{-1}L)^{3}L(-C_{2}p^{2} - B_{0,0})^{2}
\]
All the diagrams of Fig. 6 are generated by insertions of local operators of order $\mathcal{O}(Q^0)$ and a single pion exchange. It is here that we encounter for the first time the need to distinguish between the operators that make up the contact vertices. A detailed discussion is presented in Appendix C, resulting in the introduction of two new integrals, $Q_1$ and $Q_2$, in terms of which (and the integrals $P_{1,2}$ defined at NLO),

$$A_1^{(\pi)} = 2(1 + iA_{-1}L)^2(-C_2p^2 - B_{0,0})(P_1 + P_2(iA_{-1}))$$

$$2(1 + iA_{-1}L)\left(-\frac{C_2}{2}\right)(Q_1 + Q_2(iA_{-1})).$$

The new integrals are

$$Q_1 = \frac{g_A^2}{2f^2m^2\pi^2}M\left(\frac{\mu}{2}\right)^{4-D}\int \frac{d^{D-1}q}{(2\pi)^{D-1}} \frac{1}{(q - p)^2 + m^2}$$

$$PDS \rightarrow \frac{g_A^2}{2f^2m^2\pi^2}M\left(\frac{\mu - m_\pi}{4\pi}\right),$$

and

$$Q_2 = -i\frac{g_A^2}{2f^2m^2\pi^2}M^2\left(\frac{\mu}{2}\right)^{8-2D}\int \frac{d^{D-1}q}{(2\pi)^{D-1}} \frac{d^{D-1}l}{(2\pi)^{D-1}} \frac{1}{l^2 - p^2 - i\epsilon} \frac{1}{(q - p)^2 + m^2}$$

$$PDS \rightarrow -i\frac{g_A^2}{2f^2m^2\pi^2}M^2\left(\frac{\mu - m_\pi}{4\pi}\right)(\frac{\mu + ip}{4\pi}).$$
Fig. 7 describes the diagrams of this set. The graphs Fig. 7(e), (d) and (f) can be written in terms of analytic functions $I_1(p)$, $I_2(p)$ and $I_3(p)$ respectively which are presented in some detail in Appendix B. The rest of the diagrams can be written in terms of expressions that have already been defined. We write

$$iA_1^{(\pi\pi)} = -iI_1 + 2(A_{-1})I_2 + i(A_{-1})^2I_3$$

$$+ P_1(A_{-1})P_1 + 2i(A_{-1})^2P_1P_2 - (A_{-1})^3(P_2)^2.$$ 

In the last two sections, an expression for the LO+NLO+NNLO amplitude has been calculated in terms of six independent free parameters $C_0$, $B_{0,0}$, $C_2$, $B_{0,1}$, $B_{2,-1}$ and $C_4$. When the number of parameters is doubled (from NLO to NNLO) it is hard to consider an improvement of the fit as evidence for the convergence of the EFT expansion. Therefore, it is desirable to find theoretically viable ways to reduce the number of independent parameters. This is the subject of the next section.

VIII. ANALYSIS

A. Matching conditions

In this section we introduce a method for deriving conditions that reduce the number of free parameters. The guiding principal is simple: the leading couplings are defined in such a
way that certain features of the low energy data (like the effective range expansion parameters) are reproduced exactly. Conditions are then imposed on the sub-leading couplings so that these features are not modified at higher orders. Similar matching conditions were introduced in [28].

From Eq. (1.1) we get the $Q$ expansion of $p \cot \delta$ in terms of the amplitude

$$p \cot \delta = ip + \frac{4\pi}{MA_{-1}} - \frac{4\pi}{MA_{-1}A_{-1}} + \frac{4\pi}{MA_{-1}} \left( \frac{A_{0}^{2}}{A_{-1}^{2}} - \frac{A_{1}}{A_{-1}} \right) + \cdots .$$

(8.1)

At low energies, the same quantity is given by expansion (1.4):

$$p \cot \delta = -\gamma + \frac{1}{2}s_{0} \left( p^{2} + \gamma^{2} \right) + \frac{1}{2}s_{1} \left( p^{2} + \gamma^{2} \right)^{2} + \cdots .$$

(8.2)

We expand $p \cot \delta$ about $p^{2} = -\gamma^{2}$ (or $p = \pm i\gamma$).

The LO amplitude contributes only a constant to $p \cot \delta$. $C_{0}$ is determined by requiring

$$ip + \frac{4\pi}{MA_{-1}} = -\gamma .$$

(8.3)

This puts the pole in the amplitude at the right place.

At NLO and NNLO there are more constant contributions to $p \cot \delta$. The requirements that the position of the pole does not shift at NLO, nor at NNLO, reduce to:

$$\text{NLO} : \quad A_{0}|_{p=-i\gamma} = 0 \quad \text{NNLO} : \quad A_{1}|_{p=-i\gamma} = 0 .$$

(8.4)

These conditions determine the couplings $B_{0,0}$ and $B_{0,1}$. (Eqns. (8.4) can be more directly obtained by considering the expansion of the amplitude Eq. (1.5).)

Similarly, one requires that $s_{0}$ in Eq. (8.2) is determined at NLO by $C_{2}$:

$$\frac{\partial}{\partial p^{2}} \left( \frac{4\pi}{MA_{-1}A_{-1}} \right) \mid_{p^{2}=-\gamma^{2}} = \frac{1}{2}s_{0} ,$$

and that higher order (NNLO) effects do not change $s_{0}$:

$$\text{NNLO} : \quad \frac{\partial}{\partial p} A_{1}|_{p=-i\gamma} = 0 .$$

(8.5)

This condition determines $B_{2,-1}$.

Note that at NNLO, fixing $\gamma$ is not exactly the same as fitting the scattering length $a$ whereas reproducing $s_{0}$ is essentially identical to fixing the effective range, $r_{0}$.

Implementing the matching conditions Eqns (8.4) and (8.5), introduces a non-analytic $m_{\pi}$ dependence to $B_{0,0}$, $B_{0,1}$ and $B_{2,-1}$, e.g.

$$B_{0,0} = C_{2} \left( \frac{4\pi}{C_{0}M} + \mu \right)^{2} + \frac{g^{2}}{4f^{2}m_{\pi}^{2}} \left( \frac{C_{0}M}{4\pi} \right)^{2} (1 - \gamma_{E} + \ln (\pi)),
-2\ln \left( 1 + \frac{2}{m_{\pi}} \left( \frac{4\pi}{C_{0}M} + \mu \right) \right) + 2\ln \left( \frac{\mu}{m_{\pi}} \right) .$$

(8.6)

Further discussion of this point is presented in the next section.

The exact values of $\gamma$ and $s_{0}$ are used to determine $C_{0}$ and $C_{2}$. One can determine $C_{4}$ from $s_{1}$, the next free parameter in the expansion Eq. (8.2). However, as in the theory without pions (Eq. (5.1)), it can be shown, using RG analysis, that at NNLO $C_{4}$ is completely determined. This is done in the next subsection.
B. Renormalization Group Flow

In this section RG flow equations are analyzed. We discuss how constants that have $Q$ scaling, namely $\gamma$ and $m_\pi$, enter the couplings when the theory with pions is made to reproduce expansion Eq. (1.4).

The RG equations follow by requiring that the amplitude be exactly $\mu$ independent at each order in $Q$ for any value of $p$. The solutions of the RG equations for $C_0$ and $C_2$ are:

$$C_0(\mu) = \frac{4\pi}{M} \left( \frac{1}{\xi C_0} - \mu \right)^{-1}$$

$$C_2(\mu) = \xi C_2 \left( \frac{MC_0(\mu)}{4\pi} \right)^2$$

(8.7)

The integration constants $\xi_{C_0}$ and $\xi_{C_2}$ are determined by boundary conditions.

The other coupling constants, denoted here by $X$, have the general solution

$$X(\mu) = \xi_X \left( \frac{MC_0(\mu)}{4\pi} \right)^2 + f_X(C_0(\mu), B_{0,0}(\mu), C_2(\mu); \mu)$$

where $f_X$ is known, and the only freedom in $X$ is in the constant $\xi_X$, determined by boundary conditions. Specifically,

$$B_{0,0} = \left( \frac{MC_0}{4\pi} \right)^2 \left( \xi_{B_{0,0}} + \frac{g_A^2}{2f^2}m_\pi^2 \ln \left( \frac{\mu}{M} \right) \right)$$

$$B_{0,1} = \frac{B_{0,0}^2}{C_0} - \frac{g_A^2}{2f^2}m_\pi^2 \frac{M\mu}{4\pi}C_2 + \xi_{B_{0,1}} \left( \frac{MC_0}{4\pi} \right)^2$$

$$B_{2,-1} = \frac{2B_{0,0}C_2}{C_0} + \xi_{B_{2,-1}} \left( \frac{MC_0}{4\pi} \right)^2$$

$$C_4 = \frac{C_2^2}{C_0} + \xi_{C_4} \left( \frac{MC_0}{4\pi} \right)^2$$

(8.8)

Examination of the solutions Eq. (8.8) shows that the $\mu$ scaling of some couplings does not agree with their expected $Q$ counting. To determine the $Q$ counting one also needs to know the $Q$ counting of the RG constants $\xi_X$. One way of examining this without any further assumptions is by finding what values of all six parameters give reasonable fits to the data. Following this procedure we have found that at least some of the integration constants $\xi_X$ must have non-trivial $Q$ counting in order to reproduce the low energy data (note that for determining the $Q$ counting, the factors of $m_\pi$ in the definitions of the $B$ couplings must be taken into account). This result is independent of the specific form of the low energy expansion used or the particular matching conditions imposed. Using a specific fitting procedure, we have found explicit examples of $\gamma$ and $m_\pi$ entering the couplings.

That $\gamma$ can make up $Q$ counting was already shown in the theory without pions, where, for example, $C_{0,0} \sim \gamma^2/(\mu - \gamma)^2$ (see Eqns. (5.1)).

A remark about the $m_\pi$ dependence of the theory is in place. In the usual approach to EFT, the effects encapsulated in the contact interactions are the result of integrating out
fields associated with heavy particles. In the case of the two Yukawa toy model, this would mean that all the couplings - $C_s$ and $D_s$ - depend only on the details of the physics at the scale $m_\rho$, where the pion is practically massless, and one would therefore expect them to be independent of $m_\pi$. More specifically, one expects $C_0$ to be a function only of the (unnaturally small) pole in the amplitude of the high energy theory (that does not include the pions) $C_0 = C_0(\gamma_\rho)$.

It is a key feature of the KSW power counting scheme, however, that at LO the amplitude has the right pole, or the correct scattering length. This implies $C_{0,-1} = C_{0,-1}(\gamma)$. Note that in general the exact pole in the amplitude has a complicated dependence on pion physics, and in particular $\gamma = \gamma(m_\pi)$. At higher orders there are contributions from pion graphs that move the position of the pole in the amplitude, but these effects have already been accounted for. Counterterms must be introduced to cancel these effects, which are in general complicated (non-analytic) functions of $m_\pi$. This has already been shown to happen: satisfying the matching conditions Eq. (8.4) (introduced indeed to keep the pole from moving), implied explicit $m_\pi$ dependence of $B_{0,0}$ (Eq. (8.6)).

Once it is understood that RG constants such as $m_\pi$ and $\gamma$ can enter the couplings, the $\mu$ dependence is not enough for determining the $Q$ counting. It is possible, however, that a more careful statement is true, concerning the leading couplings. We demonstrate this point by discussing directly the coupling $C_4$, which has power counting of $1/Q^3$. The second term in the solution of the RG equation for $C_4$ (Eq. (8.8)) is $\sim \xi_{C_4}/\mu^2$. In order for it to contribute at NNLO, $\xi_{C_4}$ should be $O(1/Q)$. Since $C_4$ has a sensible large scattering length ($\gamma \to 0$) limit, the possibility $\xi_{C_4} \sim 1/\gamma$ is ruled out. It is also assumed that $C_4$ is fundamentally independent of pion physics, and that absorbing pion effects in it (as in going from $C_0(\gamma_\rho)$ to $C_{0,-1}(\gamma)$) introduces explicit $m_\pi$ dependence only in the sub-leading couplings. These considerations allow setting $\xi_{C_4} = 0$ at this order, and have $C_4$ be completely determined by $C_0$ and $C_2$.

There are in fact no new parameters at NNLO!

In the next subsection we check how well the EFT reproduces the phase shifts of the toy model when the matching conditions derived in the last two subsections are imposed.

**IX. RESULTS**

In this subsection we examine the EFT expansion when it is compared to the exact two Yukawa theory. We consider how well the “data” is reproduced by the EFT, whether the expansion is converging, and what is the breakdown scale.

$C_0$ is fixed at LO by $\gamma$, and $C_2$ at NLO by $\gamma$ and $s_0$. By the RG equations, $C_4 = C_2^2/C_0$.

The results are presented in Fig. 8(a). Fig. 8(b) shows the normalized errors at each order, $\Delta \equiv |\cot \delta_{\text{predicted}} - \cot \delta_{\text{exact}}|$ on a log-log scale.

The graphs show a clear improvement of the fit at NLO compared to LO. There is also improvement at NNLO, without introducing any new free parameters. The error plot shows that the errors at NNLO are smaller than those at NLO. The breakdown scale, where the errors become comparable, can be read off of the error plot to be $\sim 1000$ MeV. This is clearly an unrealistic bound since $\rho$ exchange introduces a cut in the amplitude already at $m_\rho/2$. 

16
FIG. 8. (a) The phase shift \( \delta \) for the \( ^1S_0 \) channel. (b) Log-log plot of \( \Delta \equiv |\cot \delta_{\text{predicted}} - \cot \delta_{\text{exact}}| \) vs. \( p \) (MeV). The exact phase shift is described by the solid curve. The long-dashed curves denote the LO phase shift and error, the dashed curves are the NLO results, and the dot-dashed curves describe NNLO.

The table below shows the couplings at \( \mu = m_\pi \). The entries are given in units of \( \text{fm}^2 \).

| LO | NLO | NNLO |
|----|-----|------|
| \( C_0 \) | \( C_2 m_\pi^2 \) | \( B_{0,0} \) | \( B_{2,-1} m_\pi^2 \) | \( C_4 m_\pi^4 \) |
| -3.526 | 0.06912 | 1.412 | 0.5620 | 0.2886 | -0.001355 |

From the table we see a hierarchy in the sizes of the couplings corresponding to the orders in the expansion. This is a verification of the power counting scheme. A rough estimate of the expansion parameter is \( Q \sim m_\pi/(m_\rho/2) \sim 1/3 \), which is also suggested by the table.

X. SUMMARY AND CONCLUSIONS

In this paper, an NNLO calculation for N-N scattering was presented, in the \( ^1S_0 \) channel for a two Yukawa model. This calculation also describes the potential pion contribution to the real \( ^1S_0 \) scattering data.

Matching conditions for the amplitude at low momentum were derived. These matching conditions and RG constraints were used so that no new free parameters are introduced at NNLO.

We find significant improvement at NNLO over the NLO result. From the hierarchy in the sizes of the couplings we conclude that the expansion is converging. The scale where the errors from different orders in the expansion become comparable is about 1000 MeV, which is higher than the possible breakdown scale for this theory.

The matching procedure employed in this paper could be applied to the experimental N-N scattering data. Since the relativistic corrections and radiation pion effects are small, we expect the analysis and observations in this paper to hold even for real nucleons.
We thank David Kaplan and Martin Savage for many helpful discussions. We would also like to thank the following people for providing us with interesting and useful feedback on various subjects: Paulo Bedaque, Harald Grießhammer, Dan Phillips and James Steele.

APPENDICES

In many cases it is easier to calculate the integrals in this theory in coordinate space. Finite integrals of this type are $I_1$, $I_2$ and $I_3$. When the integrals are divergent in $D = 3$ and/or $D = 4$, some care is needed\(^1\). $P_2$ is such an example.

In the following subsections, the integrals $P_2$, $I_3$ are computed in coordinate space. For $I_1$ and $I_2$, only the result is presented. In Appendix C we discuss the special integrals appearing first at NNLO when a $C_2 p^2$ acts inside a loop with a pion across.

Appendix A: $P_2$

After performing the $q^0$ integral and for convenience making the integral dimensionless, Eq. (6.2) gives

$$P_2 = -i \frac{g_A^2}{2 f^2} m_\pi^{D-6} \left( \frac{\mu}{2} \right)^{8-2D} M^2 \int \frac{d^{D-1}q}{(2\pi)^{D-1}} \frac{1}{q^2 - \rho^2 - i\epsilon} \frac{1}{1 \times (1 - \rho^2 - i\epsilon (1 - p)^2 + 1)},$$

where $\rho = p/m_\pi$ is dimensionless. Fourier transforming to coordinate space yields

$$P_2 = -i \frac{g_A^2}{2 f^2} m_\pi^{D-6} \left( \frac{\mu}{2} \right)^{8-2D} M^2 \int d^{D-1}x G_N(x)G_N(-x)G_\pi(-x),$$

where

$$G_N(x) = \int \frac{d^{D-1}q}{(2\pi)^{D-1}} \frac{e^{i\mathbf{q} \cdot \mathbf{x}}}{\mathbf{k}^2 - \rho^2 - i\epsilon}$$

$$G_\pi(x) = \int \frac{d^D q}{(2\pi)^D} \frac{e^{i\mathbf{q} \cdot \mathbf{x}}}{\mathbf{k}^2 + 1}$$

are the rescaled ($\rho = p/m_\pi$) Fourier transformed nucleon and pion propagators in $D$ dimensions respectively. Now, consider the general form

\(^1\)We would like to thank Prof. L.S. Brown for showing us how to extend the integrals off $D = 4$ dimension, and specifically for providing us with an example the calculation of $P_2$ is based upon.
\[ I = \int d^{D-1}x \prod_i G(\kappa_i; x) \]

\[ = 2\pi^{(D-1)/2} \frac{1}{\Gamma\left(\frac{D-1}{2}\right)} \frac{1}{(2\pi)^{3(D-1)/2}} \int dx x^{D-2} \prod_i \left(\frac{\kappa_i}{x}\right)^{\frac{D-3}{2}} K_{\frac{D-3}{2}}(\kappa_i x) \]

\[ = 2\pi^{(D-1)/2} \frac{1}{\Gamma\left(\frac{D-1}{2}\right)} \frac{1}{(2\pi)^{3(D-1)/2}} \int dx x^{-2D} \prod_i (\kappa_i x)^{\frac{D-3}{2}} K_{\frac{D-3}{2}}(\kappa_i x), \]

where

\[ G(\kappa_i; x) = \int \frac{d^{D-1}q}{(2\pi)^{D-1}} \frac{e^{iq\cdot x}}{\kappa_i^2 + q^2} \]

\[ \lim_{\delta \to 0} K_{\nu}(\delta) = \frac{2^{\nu-1}\Gamma(\nu)}{\delta^{\nu}}. \]

The divergence in the above integral comes from small distance \( x \), corresponding to UV divergence. The integral is split into its finite and divergent pieces as

\[ I = I^< + I^> \]

\[ I^< = 2\pi^{(D-1)/2} \frac{1}{\Gamma\left(\frac{D-1}{2}\right)} \frac{1}{(2\pi)^{3(D-1)/2}} \int_0^\delta dx x^{D-2} \prod_i (\kappa_i x)^{\frac{D-3}{2}} K_{\frac{D-3}{2}}(\kappa_i x) \]

\[ I^> = 2\pi^{(D-1)/2} \frac{1}{\Gamma\left(\frac{D-1}{2}\right)} \frac{1}{(2\pi)^{3(D-1)/2}} \int_0^\delta dx x^{D-2} \prod_i (\kappa_i x)^{\frac{D-3}{2}} K_{\frac{D-3}{2}}(\kappa_i x). \]

Integrating by parts gives

\[ I^< = 2\pi^{(D-1)/2} \frac{1}{\Gamma\left(\frac{D-1}{2}\right)} \frac{1}{(2\pi)^{3(D-1)/2}} \frac{\delta^{D-2}}{7 - 2D} \prod_i 2^{\frac{D-5}{2}} \Gamma\left(\frac{D-1}{2}\right) \]

\[ \lim_{D \to 4} - \frac{1}{32\pi^2(D-4)} + \frac{1 + \gamma_E + \ln(4\pi) + 2\ln(\delta)}{32\pi^2} + O((D-4)^1), \]

since only the surface term survives when \( \delta \to 0 \). The other integral \( I^> \) is finite in \( D = 4 \), so we get

\[ I^> = \frac{1}{16\pi^2} \int_0^{\infty} dx x^2 e^{-\kappa_1 x^3} \]

\[ = -\gamma_E + \ln(k_1 + k_2 + k_3) + \ln(\delta) \]
and so,
\[ I = I^< + I^> = -\frac{1}{32\pi^2(D-4)} + \frac{1 - \gamma_E + \ln(4\pi) - 2\ln(k_1 + k_2 + k_3)}{32\pi^2}. \]

For the integral \( P_2 \), using \( k_1 = \sqrt{-\rho^2 - i\epsilon} = k_2; \quad k_3 = 1 \), we finally have,
\[ P_2 = -i \frac{g^2}{2f^2} m_\pi^2 M^2 \frac{1}{32\pi^2} \left( -\gamma_E + 1 + \ln(\pi) - 2\ln(\frac{m_\pi}{\mu}) - 2\ln(1 - 2i\rho) \right). \]

**Appendix B: \( I_1, I_2, I_3 \)**

From Fig. 7(e), we define
\[ I_3 = -i \left( \frac{g^2}{2f^2} \right)^2 m_\pi^4 M^3 \bar{I}_3 \]
\[ \bar{I}_3 = \left\langle \int \frac{d^3k}{(2\pi)^3} \frac{1}{k^2 - p^2 - i\epsilon} I(k, p)^2 \right\rangle \]
\[ I(k, p) = \int \frac{d^3q}{(2\pi)^3} \frac{1}{q^2 - p^2 - i\epsilon} \frac{1}{(q-k)^2 + m_\pi^2} \]
where we average over the final momentum for the \(^1S_0\) state. \( I(k, p) \) is finite in \( D = 4 \) and gives
\[ I(k, p) = \frac{1}{4\pi} \int_0^{\infty} dx \frac{\sin(xk)}{xk} e^{-(m_\pi - ip)x}, \]
and so,
\[ \bar{I}_3 = \frac{1}{32\pi^4} \int dx dy e^{-((m_\pi - ip)(x+y))} \int_0^{\infty} \frac{\sin(xk) \sin(yk)}{k^2 - p^2 - i\epsilon} \]
\[ = \frac{1}{16\pi^4} \int_0^{\infty} ds \int_0^{1/2} dt e^{-(m_\pi - ip)s} \int_0^{\infty} \frac{\sin(kst) \sin(kst(1-t))}{k^2 - p^2 - i\epsilon} \]
For \( p \geq 0 \), after performing a contour integral in \( k \) we get
\[ \bar{I}_3 = \frac{i}{64\pi^3 \rho m_\pi} \int_0^{1/2} dt \frac{1}{t(1-t)} \int_0^{\infty} ds e^{-(m_\pi - ip)s} e^{-i2\pi s t} - 1 \]
\[ = \frac{i}{64\pi^3 \rho m_\pi} \left( \ln \left( \frac{1 - i\rho}{1 - i2\rho} \right) \ln(i\rho) + L_2 \left( \frac{-i\rho}{1 - i2\rho} \right) ight. \\
+ L_2(1 - i\rho) - L_2(1 - i2\rho) \)
\[ (10.1) \]
where \( \rho = p/m_\pi \)
Now, we present the result for $I_1$ and $I_2$ in terms of one dimensional finite integrals which can be done numerically or analytically, but the final expressions are not illuminating.

\[
I_1 = i \left( \frac{g^2}{2f^2} \right)^2 m_n^4 M \bar{I}_1
\]

\[
\bar{I}_1 = \left\langle \int \frac{d^3q}{(2\pi)^3} \frac{1}{q^2 - p^2 - i\epsilon} \frac{1}{(q - p)^2 + m_n^2 (q - p')^2 + m_n^2} \right\rangle
\]

\[
= \frac{1}{32\pi^3 \rho^3} (iL(\rho) + M(\rho))
\]

\[
L(\rho) = \int_0^{1/2} dt \frac{1}{t(1-t)} \ln \left( \frac{(1 + 4\rho^2 t)(1 + 4\rho^2 (1-t))}{1 + 4\rho^2} \right)
\]

\[
M(\rho) = 2 \int_0^{1/2} dt \frac{1}{t(1-t)} \left( \tan^{-1}(2\rho \sqrt{1 + 4\rho^2 t(1-t)}) - \tan^{-1}(2\rho) \right)
\]

where the average is over the outgoing momentum $p'$, and

\[
I_2 = \left( \frac{g^2}{2f^2} \right)^2 m_n^4 M^2 \bar{I}_2
\]

\[
\bar{I}_2 = \int \frac{d^3q}{(2\pi)^3} \frac{d^3l}{(2\pi)^3} \frac{1}{q^2 - p^2 - i\epsilon} \frac{1}{(q - p)^2 + m_n^2 l^2 - p^2 - i\epsilon} \frac{1}{(q - l)^2 + m_n^2}
\]

\[
= \frac{i}{128\pi^3 m_n^2 \rho} \int_{-\infty}^{\infty} dx \ln \left( \frac{i + x + \rho}{i - x + \rho} \right) \ln \left( \frac{(x + \rho)^2 + 1}{(x - \rho)^2 + 1} \right) \frac{1}{x^2 - \rho^2 - i\epsilon}
\]

**Appendix C: $Q_1, Q_2$**

In this appendix we discuss the action of a $C_2 p^2$ operator in a loop containing pions. From the Lagrangian Eq. (3.2) we rewrite the operator corresponding to $C_2$ as:

\[
\frac{C_2}{2} (q_1^2 + q_2^2)
\]

with $q_1, q_2$ the single nucleon incoming and outgoing momenta, in the center of mass system. At tree level $q_1 = q_2 = p$, and the contribution from each piece is $\frac{C_2}{2} p^2$. This is, in fact, the contribution from each piece of $C_2$ even when the legs are not external, so long as the loops attached to the vertex have no pions. In the diagrams of Fig 9 , however, corresponding to the types Fig. 6(a) and (d), the situation is different. The vertex reads $\frac{C_2}{2} (p^2 + q^2)$, with $q$ being the loop momentum. Using the fact that the loop still contains a nucleon propagator we write (after performing the $q^0$ integral):

\[
\frac{q^2}{q^2 - p^2 - i\epsilon} = 1 + \frac{p^2}{q^2 - p^2 - i\epsilon}
\]

The second term looks like the $p^2$ term; the contributions (each with $C_2/2$) add up to give
FIG. 9. Diagrams in which one cannot use the replacement $\nabla^2 \rightarrow p^2$. The integrals that result are (a) $P_1$ and $Q_1$, and (b) $P_2$ and $Q_2$.

the “naive” answer (i.e. the answer one gets by replacing $\nabla^2 \rightarrow p^2$). But the “1” remains, giving rise to different integrals.

In the case of Fig. 9(a), when the derivatives act on the external legs we get the loop integral $P_1$ as defined in Eq. (6.1); when they act on the internal legs we have

$$Q_1 \equiv \frac{g_A^2}{2f^2} \frac{m^2_\pi}{4\pi} M \left( \frac{\mu^2}{\pi^2} \right)^{4-D} \int \frac{d^{D-1}q}{(2\pi)^{D-1}} \frac{1}{(q-p)^2 + m^2_\pi}$$

Similarly the contribution from diagram Fig. 9(b) can be expressed in terms of the loop integral $P_2$ as defined in Eq. (6.2) and

$$Q_2 \equiv -i \frac{g_A^2}{2f^2} \frac{m^2_\pi}{4\pi} M \left( \frac{\mu^2}{\pi^2} \right)^{8-2D} \int \frac{d^{D-1}q}{(2\pi)^{D-1}} \frac{d^{D-1}l}{(2\pi)^{D-1}} \frac{1}{l^2 - p^2 - i\epsilon (q-p)^2 + m^2_\pi}$$

In carrying out the subtractions in $Q_1$ and $Q_2$, some care is needed. The poles and the corresponding counterterms should be calculated treating $C_0$ perturbatively.
