A Compact Embedding Theorem
for Generalized Sobolev Spaces

by Seng-Kee Chua, Scott Rodney and Richard L. Wheeden

Abstract: We give an elementary proof of a compact embedding theorem in abstract Sobolev spaces. The result is first presented in a general context and later specialized to the case of degenerate Sobolev spaces defined with respect to nonnegative quadratic forms on $\mathbb{R}^n$. Although our primary interest concerns degenerate quadratic forms, our result also applies to nondegenerate cases, and we consider several such applications, including the classical Rellich-Kondrachov compact embedding theorem and results for the class of $s$-John domains in $\mathbb{R}^n$, the latter for weights equal to powers of the distance to the boundary. We also derive a compactness result for Lebesgue spaces on quasimetric spaces unrelated to $\mathbb{R}^n$ and possibly without any notion of gradient.

1 The General Theorem

The main goal of this paper is to generalize the classical Rellich-Kondrachov theorem concerning compact embedding of Sobolev spaces into Lebesgue spaces. Our principal result applies not only to the classical Sobolev spaces on open sets $\Omega \subset \mathbb{R}^n$ but also allows us to treat the degenerate Sobolev spaces defined in [SW2], and to obtain compact embedding of them into various $L^q(\Omega)$ spaces. These degenerate Sobolev spaces are associated with quadratic forms $Q(x, \xi) = \xi^t Q(x) \xi$, $x \in \Omega, \xi \in \mathbb{R}^n$, which are nonnegative but may vanish identically in $\xi$ for some values of $x$. Such quadratic forms and Sobolev spaces arise naturally in the study of existence and regularity of weak solutions of some second order subelliptic linear/quasilinear partial differential equations; see, e.g., [SW1, 2], [R1], [MRW], [RSW].

The Rellich-Kondrachov theorem is frequently used to study the existence of solutions to elliptic equations, a famous example being subcritical and critical Yamabe equations, resulting in the solution of Yamabe’s problem; see [Y], [T], [A], [S]. Further applications lie in proving the existence of weak solutions to Dirichlet problems for elliptic equations with rough boundary data and coefficients; see [GT]. In a sequel to this paper, we will apply our compact embedding results to study the existence of solutions for some classes of degenerate equations.

\footnote{2010 Mathematics Subject Classification: 46B50, 46E35, 35H20
Key words and phrases: compact embedding, Sobolev spaces, degenerate quadratic forms}
In this section, we will state and prove our most general compact embedding results. In Sections 2 and 3, we study some applications to classical and degenerate Sobolev spaces, respectively. In Section 4, more general results in quasimetric spaces are studied.

We begin by listing some useful notation. Let \( w \) be a measure on a \( \sigma \)-algebra \( \Sigma \) of subsets of a set \( \Omega \), with \( \Omega \in \Sigma \). For \( 0 < p \leq \infty \), let \( L^p_w(\Omega) \) denote the class of real-valued measurable functions \( f \) satisfying \( \|f\|_{L^p_w(\Omega)} < \infty \), where \( \|f\|_{L^p_w(\Omega)} = \left( \int_{\Omega} |f|^p \, dw \right)^{1/p} \) if \( p < \infty \) and \( \|f\|_{L^\infty_w(\Omega)} = \text{ess sup}_{\Omega} |f| \), the essential supremum being taken with respect to \( w \)-measure. When dealing with generic functions in \( L^p_w(\Omega) \), we will not distinguish between functions which are equal a.e.-\( w \). For \( E \in \Sigma \), \( w(E) \) denotes the \( w \)-measure of \( E \), and if \( 0 < w(E) < \infty \) then \( f_{E,w} \) denotes the \( w \)-average of \( f \) over \( E \): \( f_{E,w} = \frac{1}{w(E)} \int_E f \, dw \). Throughout the paper, positive constants will be denoted by \( C \) or \( c \) and their dependence on important parameters will be indicated.

For \( k \in \mathbb{N} \), let \( X(\Omega) \) be a normed linear space of measurable \( \mathbb{R}^k \)-valued functions \( g \) defined on \( \Omega \) with norm \( \|g\|_X(\Omega) \).

This is a normed linear space with norm

\[
\|(f, g)\|_{L^N_w(\Omega) \times X(\Omega)} = \|f\|_{L^N_w(\Omega)} + \|g\|_{X(\Omega)}.
\]  

A set \( S \subset L^N_w(\Omega) \times X(\Omega) \) will be called a bounded set in \( L^N_w(\Omega) \times X(\Omega) \) if

\[
\sup_{(f, g) \in S} \|(f, g)\|_{L^N_w(\Omega) \times X(\Omega)} < \infty.
\]  

Projection maps such as the one defined by

\[
\pi : (f, g) \to f, \quad (f, g) \in L^N_w(\Omega) \times X(\Omega),
\]  

(1.2)
will play a role in our results. If \( w(\Omega) < \infty \), then \( \pi(\mathcal{L}_w^N(\Omega) \times \mathcal{X}(\Omega)) \subset L_w^q(\Omega) \) if \( 1 \leq q \leq N \).

**Theorem 1.1.** Let \( w \) be a finite measure on a \( \sigma \)-algebra \( \Sigma \) of subsets of a set \( \Omega \), with \( \Omega \in \Sigma \). Let \( 1 \leq p < \infty, \, 1 < N \leq \infty \), \( \mathcal{X}(\Omega) \) be a normed linear space satisfying properties (A) and \((B_p)\) relative to a collection \( \Sigma_0 \subset \Sigma \), and let \( S \) be a bounded set in \( \mathcal{L}_w^N(\Omega) \times \mathcal{X}(\Omega) \).

Suppose that \( S \) satisfies the following: given \( \epsilon > 0 \), there are a finite number of pairs \( \{E_t, F_t\}_{t=1}^J \) with \( E_t \in \Sigma \) and \( F_t \in \Sigma_0 \) (the pairs and \( J \) may depend on \( \epsilon \)) such that

1. \( w(\Omega \setminus \bigcup E_t) < \epsilon \) and \( w(E_t) > 0 \);
2. \( \{F_t\} \) has bounded overlaps independent of \( \epsilon \) with the same overlap constant as in \((B_p)\), i.e.,
   \[
   \sum_{t=1}^J \chi_{F_t}(x) \leq C_1, \quad x \in \Omega, \tag{1.3}
   \]
3. for every \( (f, g) \in S \), the local Poincaré-type inequality
   \[
   ||f - f_{E_t, w}||_{L_w^p(E_t)} \leq \epsilon ||g\chi_{F_t}||_{\mathcal{X}(\Omega)} \tag{1.4}
   \]
holds for each \( (E_t, F_t) \).

Let \( \hat{S} \) be the set defined by

\[
\hat{S} = \{ f \in \mathcal{L}_w^N(\Omega) : \text{there exists } \{(f^j, g^j)\}_{j=1}^\infty \subset S \text{ with } f^j \to f \text{ a.e.-}w \}. \tag{1.5}
\]

Then \( \hat{S} \) is compactly embedded in \( L_w^q(\Omega) \) if \( 1 \leq q < N \) in the sense that for every sequence \( \{f_k\} \subset \hat{S} \), there is a single subsequence \( \{f_{k_j}\} \) and a function \( f \in \mathcal{L}_w^N(\Omega) \) such that \( f_{k_j} \to f \text{ pointwise a.e.-}w \) in \( \Omega \) and in \( L_w^q(\Omega) \) norm for \( 1 \leq q < N \).

Before proceeding with the proof of Theorem 1.1, we make several simple observations. First, in the definition of \( \hat{S} \), the property that \( f \in \mathcal{L}_w^N(\Omega) \) follows by Fatou’s lemma since the associated functions \( f^j \) are bounded in \( \mathcal{L}_w^N(\Omega) \), as \( S \) is bounded in \( \mathcal{L}_w^N(\Omega) \times \mathcal{X}(\Omega) \) by hypothesis. Fatou’s lemma also shows that \( \hat{S} \) is a bounded set in \( \mathcal{L}_w^N(\Omega) \). Moreover, since \( N > 1 \), if \( \{f^j\} \) is bounded in \( \mathcal{L}_w^N(\Omega) \) and \( f^j \to f \text{ a.e.-}w \), then \( (f^j)_{E, w} \to f_{E, w} \) for all \( E \in \Sigma \); in fact, in this situation, by using Egorov’s theorem, we have \( \int f^j \varphi dw \to \int f \varphi dw \) for all \( \varphi \in \mathcal{L}_w^{N'}(\Omega), \, 1/N + 1/N' = 1 \).
Next, while the hypothesis \( w(E_\ell) > 0 \) in assumption (i) ensures that the averages \( f_{E_\ell, w} \) in (1.4) are well-defined, it is not needed since we can discard any pair \( E_\ell, F_\ell \) with \( w(E_\ell) = 0 \) without affecting the inequality \( w(\Omega \setminus \bigcup \Omega_\ell) < \epsilon \) or (1.3) and (1.4).

Finally, since \( \hat{S} \) contains the first component \( f \) of any pair \( (f, g) \in S \), a simple corollary of Theorem 1.1 is that the projection \( \pi \) defined in (1.2) is a compact mapping of \( S \) into \( L^q_w(\Omega) \), \( 1 \leq q < N \), in the sense that for every sequence \( \{(f_k, g_k)\} \subset S \), there is a subsequence \( \{f_{k_i}\} \) and a function \( f \in L^N_w(\Omega) \) such that \( f_{k_i} \to f \) pointwise a.e.-w in \( \Omega \) and in \( L^q_w(\Omega) \) norm for \( 1 \leq q < N \).

**Proof:** Let \( S \) satisfy the hypotheses and suppose \( \{f_k\}_{k \in \mathbb{N}} \subset \hat{S} \). For each \( f_k \), use the definition of \( \hat{S} \) to choose a sequence \( \{(f^j_k, g^j_k)\} \subset S \) with \( f^j_k \to f_k \) a.e.-w as \( j \to \infty \). Since \( S \) is bounded in \( L^N_w(\Omega) \times \mathcal{X}(\Omega) \), there is \( M \in (0, \infty) \) so that \( \|(f^j_k, g^j_k)\|_{L^N_w(\Omega) \times \mathcal{X}(\Omega)} \leq M \) for all \( k \) and \( j \). Also, as noted above, \( \{f_k\} \) is bounded in \( L^N_w(\Omega) \) norm; in fact \( \|f_k\|_{L^N_w(\Omega)} \leq M \) for the same constant \( M \) and all \( k \).

Since \( \{f_k\} \) is bounded in \( L^N_w(\Omega) \), then if \( 1 < N < \infty \), it has a weakly convergent subsequence, while if \( N = \infty \), it has a subsequence which converges in the weak-star topology. In either case, we relabel the subsequence as \( \{f_k\} \) to preserve the index. Fix \( \epsilon > 0 \) and let \( \{E_\ell, F_\ell\}_{\ell=1}^J \) satisfy the hypotheses of the theorem relative to \( \epsilon \). Setting \( \Omega^\epsilon = \bigcup \Omega_\ell \), we have by assumption (i) that

\[
w(\Omega \setminus \Omega^\epsilon) < \epsilon. \tag{1.6}\]

Let us show that there is a positive constant \( C \) independent of \( \epsilon \) so that

\[
\sum_{\ell} \|f_k - (f_k)_{E_\ell, w}\|_{L^p_w(E_\ell)}^p \leq C\epsilon^p \tag{1.7}
\]

Fix \( k \) and let \( \Delta \) denote the expression on the left side of (1.7). Since \( f^j_k - (f^j_k)_{E_\ell, w} \to f_k - (f_k)_{E_\ell, w} \) a.e.-w as \( j \to \infty \), Fatou’s lemma gives

\[
\Delta \leq \sum_{\ell} \liminf_{j \to \infty} \|f^j_k - (f^j_k)_{E_\ell, w}\|_{L^p_w(E_\ell)}^p.
\]

Consequently, by using the Poincaré inequality (1.4) for \( S \) and superadditivity of \( \liminf \), we obtain

\[
\Delta \leq \liminf_{j \to \infty} \sum_{\ell} \epsilon^p \|g^j_k\chi_{F_\ell}\|_{\mathcal{X}(\Omega)}^p.
\]
By (1.3), the sets $F_\ell$ have finite overlaps uniformly in $\epsilon$, with the same overlap
constant $C_1$ as in property ($B_p$) of $\mathcal{X}(\Omega)$. Hence, by property ($B_p$) applied to the
last expression together with boundedness of $\mathcal{S}$,

$$
\Delta \leq C_2 \epsilon^p \liminf_{j \to \infty} ||g_j^i||_{\mathcal{X}(\Omega)}^p \leq C_2 M^p \epsilon^p.
$$

This proves (1.7) with $C = C_2 M^p$.

Next note that

$$
\int_{\hat{\Omega}} |f_m - f_k|^p dw \leq \sum_\ell \int_{E_\ell} |f_m - f_k|^p dw
\leq 2^{p-1} \left( \sum_\ell \int_{E_\ell} |f_m - f_k - (f_m - f_k)_{E_\ell,w}|^p dw + \sum_\ell |(f_m - f_k)_{E_\ell,w}|^p w(E_\ell) \right)
= 2^{p-1}(I + II).
$$

We will estimate I and II separately. We have

$$
I \leq 2^{p-1} \left( \sum_\ell \|f_m - (f_m)_{E_\ell,w}\|_{L^p_w(E_\ell)}^p + \sum_\ell \|f_k - (f_k)_{E_\ell,w}\|_{L^p_w(E_\ell)}^p \right)
\leq 2^{p-1}(C \epsilon^p + C \epsilon^p) = 2^p C \epsilon^p
$$

by (1.7). To estimate II, first note that

$$
II = \sum_{\ell=1}^J |(f_m - f_k)_{E_\ell,w}|^p w(E_\ell) = \sum_{\ell=1}^J \frac{1}{w(E_\ell)^{p-1}} \left| \int_{\Omega} (f_m - f_k) \chi_{E_\ell} dw \right|^p.
$$

Since $w(\Omega) < \infty$, each characteristic function $\chi_{E_\ell} \in L^{N'}_w(\Omega)$, $1/N + 1/N' = 1$
(with $N' = 1$ if $N = \infty$). As $\{f_k\}$ converges weakly in $L^N_w(\Omega)$ when $1 < N < \infty$,
or converges in the weak-star sense when $N = \infty$, then for $m,k$ sufficiently large
depending on $\epsilon$, and for all $1 \leq \ell \leq J$,

$$
\frac{1}{w(E_\ell)^{p-1}} \left| \int_{\Omega} (f_m - f_k) \chi_{E_\ell} dw \right|^p \leq \frac{\epsilon^p}{J}.
$$
Thus $II \leq \epsilon^p$ for $m, k$ sufficiently large depending on $\epsilon$. Combining this estimate with (1.8) and (1.9) shows that

$$\|f_m - f_k\|_{L^q_w(\Omega')} < C\epsilon$$  \hspace{1cm} (1.10)

for $m, k$ sufficiently large and $C = C(M, C_2)$.

Let us now show that $\{f_k\}$ is a Cauchy sequence in $L^1_w(\Omega)$. For $m, k$ as in (1.10), Hölder’s inequality and the fact that $||f_k||_{L^\infty_w(\Omega)} \leq M$ for all $k$ yield

$$\|f_m - f_k\|_{L^1_w(\Omega)} \leq \|f_m - f_k\|_{L^p_w(\Omega')} + \|f_m - f_k\|_{L^q_w(\Omega')}$$

$$\leq \|f_m - f_k\|_{L^p_w(\Omega')} w(\Omega')^{\frac{1}{p'}} + \|f_m - f_k\|_{L^q_w(\Omega')} w(\Omega' \setminus \Omega^e)^{\frac{1}{q'}}$$

$$< Ce^{-\epsilon^{q'}} + 2M\epsilon^{\frac{1}{q'}} \text{ by (1.6).}$$

Since $N' < \infty$, it follows that $\{f_k\}$ is Cauchy in $L^1_w(\Omega)$. Hence it has a subsequence (again denoted by $\{f_k\}$) that converges in $L^1_w(\Omega)$ and pointwise a.e. in $\Omega$ to a function $f \in L^1_w(\Omega)$. If $N = \infty$, $\{f_k\}$ is bounded in $L^\infty_w(\Omega)$ by hypothesis, so its pointwise limit $f \in L^\infty_w(\Omega)$. If $N < \infty$, since $\{f_k\}$ is bounded in $L^N_w(\Omega)$, Fatou’s Lemma implies that $f \in L^N_w(\Omega)$. This completes the proof in case $q = 1$.

For general $q$, we will use the same subsequence $\{f_k\}$ as above. Thus we only need to show that $\{f_k\}$ converges in $L^1_w(\Omega)$ for $1 < q < N$. We will use Hölder’s inequality. Given $q \in (1, N)$, choose $\lambda \in (0, 1)$, namely $\lambda = \left(\frac{1}{q} - \frac{1}{N}\right)/(1 - \frac{1}{N})$, hence $\lambda = 1/q$ if $N = \infty$, so that

$$\|f_m - f_k\|_{L^\lambda_w(\Omega)} \leq \|f_m - f_k\|_{L^\lambda_w(\Omega)}^{\frac{1}{\lambda}} \|f_m - f_k\|_{L^\lambda_w(\Omega)}^{1 - \frac{1}{\lambda}}.$$  \hspace{1cm} (1.11)

As before, $\|f_k\|_{L^\lambda_w(\Omega)} \leq M$, and therefore $\|f_m - f_k\|_{L^\lambda_w(\Omega)}^{1 - \frac{1}{\lambda}} \leq (2M)^{1 - \lambda}$, giving by (1.11) that $\{f_k\}$ is Cauchy in $L^\lambda_w(\Omega)$ as it is Cauchy in $L^1_w(\Omega)$. This completes the proof of Theorem 1.1. \square

A compact embedding result is also proved in [FSSC, Theorem 3.4] by using Poincaré type estimates. However, Theorem 1.1 applies to situations not considered in [FSSC] since it is not restricted to the context of Lipschitz vector fields in $\mathbb{R}^n$. Other abstract compact embedding results can be found in [HK1, Theorem 4] and [HK2, Theorem 8.1], including a version (see [HK1, Theorem 5]) for weighted Sobolev spaces with nonzero continuous weights, and a version in [HK2] for metric spaces with a single doubling measure. The proof in [HK1] assumes prior knowledge of the classical Rellich-Kondrachov compactness theorem (see e.g.
By making minor changes in the proof of Theorem 1.1, we can obtain a sufficient condition for a bounded set in $L^N_w(\Omega)$ to be precompact in $L^q_w(\Omega)$, $1 \leq q < N$, without mentioning the sets $\{F_\ell\}$, the space $E(\Omega)$, properties (A) and (B$_p$), or conditions (1.3) and (1.4). We state this result in the next theorem. An application is given in §4.

**Theorem 1.2.** Let $w$ be a finite measure on a $\sigma$-algebra $\Sigma$ of subsets of a set $\Omega$, with $\Omega \in \Sigma$. Let $1 \leq p < \infty$, $1 < N \leq \infty$ and $\mathcal{P}$ be a bounded subset of $L^N_w(\Omega)$. Suppose there is a positive constant $C$ so that for every $\epsilon > 0$, there are a finite number of sets $E_\ell \in \Sigma$ with

(i) $w(\Omega \setminus \cup_\ell E_\ell) < \epsilon$ and $w(E_\ell) > 0$;
(ii) for every $f \in \mathcal{P}$,
$$\sum_\ell ||f - f_{E_\ell,w}||_{L^p_w(E_\ell)}^p \leq C\epsilon^p.$$  
(1.12)

Let
$$\hat{\mathcal{P}} = \{f \in L^N_w(\Omega) : \text{there exists } \{f^j\} \subset \mathcal{P} \text{ with } f^j \to f \text{ a.e.-}w \}.$$

Then for every sequence $\{f_k\} \subset \hat{\mathcal{P}}$, there is a single subsequence $\{f_{k_l}\}$ and a function $f \in L^N_w(\Omega)$ such that $f_{k_l} \to f$ pointwise a.e.-$w$ in $\Omega$ and in $L^q_w(\Omega)$ norm for $1 \leq q < N$.

**Remark 1.3.**

1. Given $\epsilon > 0$, let $\{E_\ell\}$ satisfy hypothesis (i) of Theorem 1.2. Hypothesis (ii) of Theorem 1.2 is clearly true for $\{E_\ell\}$ if for every $f \in \mathcal{P}$, there are nonnegative constants $\{a_\ell\}$ such that
$$||f - f_{E_\ell,w}||_{L^p_w(E_\ell)} \leq \epsilon a_\ell$$
(1.13)
and
$$\sum_\ell a_\ell^p \leq C$$
(1.14)
with $C$ independent of $f, \epsilon$. The constants $\{a_\ell\}$ may vary with $f$ and $\epsilon$.

2. Theorem 1.1 is a corollary of Theorem 1.2. To see why, suppose that the hypothesis of Theorem 1.1 holds. Define $\mathcal{P}$ by $\mathcal{P} = \pi(\mathcal{S}) = \{f : (f, g) \in \mathcal{S}\}$. Let $\epsilon > 0$ and choose $\{(E_\ell, F_\ell)\}$ as in Theorem 1.1. Given $f \in \mathcal{P}$, choose any $g$ such that $(f, g) \in \mathcal{S}$ and set $a_\ell = ||g_{F_\ell}||_{E(\Omega)}$ for all $\ell$. Then (1.4), (1.3) and property (B$_p$) of $E(\Omega)$ imply (1.13) and (1.14). The preceding remark shows that the hypothesis of Theorem 1.2 holds. The conclusion of Theorem 1.1 now follows from Theorem 1.2.
Proof of Theorem 1.2: Theorem 1.2 can be proved by checking through the proof of Theorem 1.1. In fact, the nature of hypothesis (1.12) allows simplification of the proof. First recall that if $f^j \to f$ a.e.-$w$ and $\{f^j\}$ is bounded in $L^N_w(\Omega)$, then $(f^j)_{E,w} \to f_{E,w}$ for every $E \in \Sigma$. Therefore, by the definition of $\mathcal{P}$ and Fatou’s lemma, the truth of (1.12) for all $f \in \mathcal{P}$ implies its truth for all $f \in ˆ\mathcal{P}$. Given a sequence $\{f_k\}$ in $\mathcal{P}$, we follow the proof of Theorem 1.1 but no longer need to introduce the $\{f^j_k\}$ or prove (1.7) since (1.7) now follows from the fact that (1.12) holds for $\mathcal{P}$. Further details are left to the reader. □

We close this section by listing an alternate version of Theorem 1.1 that we will use in §3.4 when we consider local results.

Theorem 1.4. Let $w$ be a measure (not necessarily finite) on a $\sigma$-algebra $\Sigma$ of subsets of a set $\Omega$, with $\Omega \in \Sigma$. Let $1 \leq p < \infty$, $1 < N \leq \infty$, $\mathcal{X}(\Omega)$ be a normed linear space satisfying properties (A) and $(B_p)$ relative to a set $\Sigma_0 \subset \Sigma$, and let $\mathcal{S}$ be a collection of pairs $(f, g)$ such that $f$ is $\Sigma$-measurable and $g \in \mathcal{X}(\Omega)$.

Suppose that $\mathcal{S}$ satisfies the following conditions relative to a fixed set $\Omega' \in \Sigma$ (in particular $\Omega' \subset \Omega$): for each $\epsilon = \epsilon_j = 1/j$ with $j \in \mathbb{N}$, there are a finite number of pairs $\{E^\epsilon_\ell, F^\epsilon_\ell\}_\ell$ with $E^\epsilon_\ell \in \Sigma$ and $F^\epsilon_\ell \in \Sigma_0$ such that

(i) $w(\Omega' \setminus \bigcup_\ell E^\epsilon_\ell) = 0$ and $0 < w(E^\epsilon_\ell) < \infty$;

(ii) $\{F^\epsilon_\ell\}_\ell$ has bounded overlaps independent of $\epsilon$ with the same overlap constant as in $(B_p)$, i.e.,

$$\sum_\ell \chi_{F^\epsilon_\ell}(x) \leq C_1, \quad \text{for } x \in \Omega,$$

for $C_1$ as in $(B_p)$;

(iii) for every $(f, g) \in \mathcal{S}$, the local Poincaré-type inequality

$$\|f - f_{E^\epsilon_\ell,w}\|_{L^p_w(E^\epsilon_\ell)} \leq \epsilon \|g\chi_{F^\epsilon_\ell}\|_{\mathcal{X}(\Omega)}$$

holds for each $(E^\epsilon_\ell, F^\epsilon_\ell)$.

Then for every sequence $\{(f_k, g_k)\}$ in $\mathcal{S}$ with

$$\sup_k \left[ \|f_k\|_{L^p_w(\Omega')} + \|g_k\|_{\mathcal{X}(\Omega)} \right] < \infty,$$  \hspace{1cm} (1.15)

there is a subsequence $\{f_{k_i}\}$ of $\{f_k\}$ and a function $f \in L^N_w(\Omega')$ such that $f_{k_i} \to f$ pointwise a.e.-$w$ in $\Omega'$ and in $L^q_w(\Omega')$ norm for $1 \leq q \leq p$. If $p < N$, then also $f_{k_i} \to f$ in $L^q_w(\Omega')$ norm for $1 \leq q < N$. 

The principal difference between the assumptions in Theorems 1.1 and 1.4 occurs in hypothesis (i). When we apply Theorem 1.4 in §3.4, the sets \( \{ E_\epsilon \} \) will satisfy \( \Omega' \subset \cup_\epsilon E_\epsilon \) for each \( \epsilon \), and consequently the condition in hypothesis (i) that 
\[
\mathcal{w}(\Omega' \setminus \cup_\epsilon E_\epsilon) = 0
\]
for each \( \epsilon \) will be automatically true. Unlike Theorem 1.1, the value of \( q \) in Theorem 1.4 is always allowed to equal \( p \). Although \( \mathcal{w}(\Omega) \) is not assumed to be finite in Theorem 1.4, \( \mathcal{w}(\Omega') < \infty \) is true due to hypothesis (i) and the fact that the number of \( E_\epsilon \) is finite for each \( \epsilon \). As in Theorem 1.1, the hypothesis \( \mathcal{w}(E_\epsilon) > 0 \) is dispensible.

**Proof of Theorem 1.4:** The proof is like that of Theorem 1.1, with minor changes and some simplifications. We work directly with the pairs \((f_k, g_k)\) without considering approximations \((f^j_k, g^j_k)\). Due to the form of assumption (i) in Theorem 1.4, neither the set \( \Omega' \) nor estimate (1.6) is now needed. Since \( \mathcal{w}(\Omega' \setminus \cup_\epsilon E_\epsilon) = 0 \) for each \( \epsilon = 1/j \), we can replace \( \Omega \) by \( \Omega' \) in the proof, obtaining the estimate
\[
|f_m - f_k|_{L^p_w(\Omega')} < C\epsilon
\]
as an analogue of (1.10). In deriving (1.16), the weak and weak-star arguments are guaranteed since by (1.15),
\[
\sup_k |f_k|_{L^q_w(\cup_\epsilon E_\epsilon^{1/j})} < \infty.
\]
The main change in the proof comes by observing that the entire argument formerly used to show that \( \{ f_k \} \) is Cauchy in \( L^1_w(\Omega) \) is no longer needed. In fact, (1.16) proves that \( \{ f_k \} \) is Cauchy in \( L^p_w(\Omega') \), and therefore it is also Cauchy in \( L^q_w(\Omega') \) if \( 1 \leq q < p \) since \( \mathcal{w}(\Omega') < \infty \). The first conclusion in Theorem 1.4 then follows. To prove the second one, assuming that \( p, q < N \), we use an analogue of (1.11) with \( \Omega' \) in place of \( \Omega \) and the same choice of \( \lambda \), namely,
\[
|f_m - f_k|_{L^q_w(\Omega')} \leq |f_m - f_k|_{L^q_w(\Omega')}^{\lambda} |f_m - f_k|_{L^q_w(\Omega')}^{1-\lambda}.
\]
The desired conclusion then follows as before since we have already shown that the first factor on the right side tends to 0.

2 Applications in the Nondegenerate Case

Roughly speaking, a consequence of Theorem 1.1 is that a set of functions which is bounded in \( L^N_w(\Omega) \) is precompact in \( L^q_w(\Omega) \) for \( 1 \leq q < N \) if the gradients of the functions are bounded in an appropriate norm, and a *local* Poincaré inequality holds.
for them. The requirement of boundedness in $L^N_w(\Omega)$ will be fulfilled if, for example, the functions satisfy a *global* Poincaré or Sobolev estimate with exponent $N$ on the left-hand side. In order to illustrate this principle more precisely, we first consider the classical gradient operator and functions on $\mathbb{R}^n$ with the standard Euclidean metric. We include a simple way to see that the Rellich-Kondrachov compactness theorem follows from our results. Our derivation of this fact is different from those in [AF] and [GT]; in particular, it avoids using the Arzelá-Ascoli theorem and regularization of functions by convolution. We also list compactness results for the special class of $s$-John domains in $\mathbb{R}^n$. In [HK1], the authors mention that such results follow from their development without giving specific statements. See also [HK2, Theorem 8.1]. We list results for degenerate quadratic forms and vector fields in Section 3.

We begin by proving a compact embedding result for some Sobolev spaces involving two measures. Let $w$ be a measure on the Borel subsets of a fixed open set $\Omega \subset \mathbb{R}^n$, and let $\mu$ be a measure on the $\sigma$-algebra of Lebesgue measurable subsets of $\Omega$. We also assume that $\mu$ is absolutely continuous with respect to Lebesgue measure. If $1 \leq p < \infty$, let $E^p_\mu(\Omega)$ denote the class of locally Lebesgue integrable functions on $\Omega$ with distributional derivatives in $L^p_\mu(\Omega)$. If $1 \leq N \leq \infty$, we say that a set $Y \subset L^N_w(\Omega) \cap E^p_\mu(\Omega)$ (intersection of function spaces instead of normed spaces of equivalence classes) is *bounded* in $L^N_w(\Omega) \cap E^p_\mu(\Omega)$ if

$$\sup_{f \in Y} \{ ||f||_{L^N_w(\Omega)} + ||\nabla f||_{L^p_\mu(\Omega)} \} < \infty.$$ 

We use $D$ to denote a generic open Euclidean ball. The radius and center of $D$ will be denoted $r(D)$ and $x_D$, and if $C$ is a positive constant, $CD$ will denote the ball concentric with $D$ whose radius is $Cr(D)$.

**Theorem 2.1.** Let $\tilde{\Omega} \subset \Omega$ be open sets in $\mathbb{R}^n$. Let $w$ be a Borel measure on $\Omega$ with $w(\tilde{\Omega}) = w(\Omega) < \infty$ and $\mu$ be a measure on the Lebesgue measurable sets in $\Omega$ which is absolutely continuous with respect to Lebesgue measure. Let $1 \leq p < \infty$, $1 < N \leq \infty$ and $\mathcal{F} \subset L^N_w(\Omega) \cap E^p_\mu(\Omega)$, and suppose that for all $\epsilon > 0$, there exists $\delta_\epsilon > 0$ such that

$$||f - f_{D,w}||_{L^N_w(D)} \leq \epsilon ||\nabla f||_{L^p_\mu(D)} \text{ for all } f \in \mathcal{F}$$

(2.1)

and all Euclidean balls $D$ with $r(D) < \delta_\epsilon$ and $2D \subset \tilde{\Omega}$. Then for any sequence $\{f_k\} \subset \mathcal{F}$ that is bounded in $L^N_w(\Omega) \cap E^p_\mu(\Omega)$, there is a subsequence $\{f_{k_i}\}$ and a function $f \in L^N_w(\Omega)$ such that $\{f_{k_i}\} \rightarrow f$ pointwise a.e.-w in $\Omega$ and in $L^q_w(\Omega)$ norm for $1 \leq q < N$. 

Before proving Theorem 2.1, we give typical examples of \( \tilde{\Omega} \) and \( w \) with \( w(\tilde{\Omega}) = w(\Omega) < \infty \). For any two nonempty sets \( E_1, E_2 \subset \mathbb{R}^n \), let
\[
\rho(E_1, E_2) = \inf\{|x - y| : x \in E_1, y \in E_2\}
\] (2.2)
denote the Euclidean distance between \( E_1 \) and \( E_2 \). If \( x \in \mathbb{R}^n \) and \( E \) is a nonempty set, we will write \( \rho(x, E) \) instead of \( \rho(\{x\}, E) \). Let \( \tilde{\Omega} \) be an open subset of \( \Omega \). If \( \Omega \) is bounded and \( \Omega \setminus \tilde{\Omega} \) has Lebesgue measure 0, the measure \( w \) on \( \Omega \) defined by \( dw = \rho(x, \mathbb{R}^n \setminus \tilde{\Omega})^\alpha dx \) clearly has the desired properties if \( \alpha \geq 0 \). The range of \( \alpha \) can be increased to \( \alpha > 1 \) if \( \Omega \) is a Lipschitz domain and \( \Omega \setminus \tilde{\Omega} \) is a finite set. Indeed, if \( \partial \Omega \) is described in local coordinates \( x = (x_1, \ldots, x_n) \) by \( x_n = F(x_1, \ldots, x_{n-1}) \) with \( F \) Lipschitz, then the distance from \( x \) to \( \partial \Omega \) is equivalent to \( |x_n - F(x_1, \ldots, x_{n-1})| \), and consequently the restriction \( \alpha > 1 \) guarantees that \( w \) is finite near \( \partial \Omega \) by using Fubini’s theorem; see also [C1, Remark 3.4(b)]. If \( \Omega \) is bounded and \( \Omega \setminus \tilde{\Omega} \) is finite, but with no restriction on \( \partial \Omega \), the range can clearly be further increased to \( \alpha > -n \) for the measure \( \rho(x, \Omega \setminus \tilde{\Omega})^\alpha dx \). Also note that any \( w \) without point masses satisfies \( w(\tilde{\Omega}) = w(\Omega) \) if \( \tilde{\Omega} \) is obtained by deleting a countable subset of \( \Omega \).

**Proof of Theorem 2.1:** We will verify the hypotheses of Theorem 1.1. Let
\[
\mathcal{X}(\Omega) = \{g = (g_1, \ldots, g_n) : |g| = \left( \sum_{i=1}^n g_i^2 \right)^{1/2} \in L_\mu^p(\Omega) \}
\]
and \( \|g\|_{\mathcal{X}(\Omega)} = \|g\|_{L_\mu^p(\Omega)} \). Then
\[
\|\nabla f\|_{\mathcal{X}(\Omega)} = \|\nabla f\|_{L_\mu^p(\Omega)} \quad \text{if} \quad f \in E_\mu^p(\Omega).
\]
If \( f \in E_\mu^p(\Omega) \), we may identify \( f \) with the pair \((f, \nabla f)\) since the distributional gradient \( \nabla f \) is uniquely determined by \( f \) up to a set of Lebesgue measure zero. Then \( L_\mu^p(\Omega) \cap E_\mu^p(\Omega) \) can be viewed as a subset of \( L_\mu^N(\Omega) \times \mathcal{X}(\Omega) \). In Theorem 1.1, choose \( \mathcal{S} \) to be the particular sequence \( \{f_k\} \subset \mathcal{S} \) in the hypothesis of Theorem 2.1, and choose \( \Sigma \) to be the Lebesgue measurable subsets of \( \Omega \) and \( \Sigma_0 \) to be the collection of balls \( D \subset \Omega \). Then hypotheses (A) and (B_p) are valid with \( C_2 = C_1 \) for any \( C_1 \). Given \( \epsilon > 0 \), since \( w(\tilde{\Omega}) = w(\Omega) < \infty \), there is a compact set \( K \subset \tilde{\Omega} \) with \( w(\tilde{\Omega} \setminus K) < \epsilon \). Let \( 0 < \delta' < \rho(K, \mathbb{R}^n \setminus \tilde{\Omega}) \) (where \( \rho(K, \mathbb{R}^n \setminus \tilde{\Omega}) \) is interpreted as \( \infty \) if \( \tilde{\Omega} = \mathbb{R}^n \)), let \( \delta' \) be as in (2.1), and fix \( r_\epsilon \) with \( 0 < r_\epsilon < \min\{\delta, \delta'\} \). By considering the triples of balls in a maximal collection of pairwise disjoint balls of radius \( r_\epsilon/6 \) centered in \( K \), we obtain a collection \( \{E_\epsilon\}_\ell \) of balls of radius \( r_\epsilon/2 \) which satisfy \( 2E_\epsilon \subset \tilde{\Omega} \), have bounded overlaps with overlap constant independent
of $\epsilon$, and whose union covers $K$. Since $K$ is compact, we may assume the collection is finite. Also,

$$w(\Omega \setminus \cup_{\ell \in \ell'} E^\epsilon_{\ell}) \leq w(\Omega \setminus K) < \epsilon,$$

and (1.4) holds with $F_{\ell} = E_{\ell} = E^\epsilon_{\ell}$ by (2.1). Theorem 2.1 now follows from Theorem 1.1 applied to $\Omega$.

In particular, we obtain the following result when $w = \mu$ is a Muckenhoupt $A_p(\mathbb{R}^n)$ weight, i.e., when $d\mu = dw = \eta dx$ where $\eta(x)$ satisfies

$$\left(\frac{1}{|D|} \int_D \eta dx\right) \left(\frac{1}{|D|} \int_D \eta^{-1/(p-1)} dx\right)^{p-1} \leq C$$

if $1 < p < \infty$ and $|D|^{-1} \int_D \eta dx \leq C \text{essinf}_D w$ if $p = 1$ for all Euclidean balls $D$, with $C$ independent of $D$. As is well known, such a weight also satisfies the classical doubling condition

$$w(D_r(x)) \leq C \left(\frac{r}{r'}\right)^{\theta} w(D_{r'}(x)), \quad 0 < r' < r < \infty,$$

with $\theta \geq np - \epsilon$ for some $\epsilon > 0$ if $p > 1$, and with $\theta = n$ if $p = 1$, where $C$ and $\theta$ are independent of $r, r', x$.

We denote by $W^{1,p,w}(\Omega)$ the weighted Sobolev space defined as all functions in $L^p_w(\Omega)$ whose distributional gradient is in $L^p_w(\Omega)$. Thus $W^{1,p,w}(\Omega) = L^p_w(\Omega) \cap E^p_w(\Omega)$. If $w(\Omega) < \infty$, it follows that $L^N_w(\Omega) \cap E^p_w(\Omega) \subset W^{1,p,w}(\Omega)$ when $N \geq p$, and that the opposite containment holds when $N \leq p$.

**Theorem 2.2.** Let $1 \leq p < \infty$, $w \in A_p(\mathbb{R}^n)$ and $\Omega$ be an open set in $\mathbb{R}^n$ with $w(\Omega) < \infty$. If $1 < N \leq \infty$, then any bounded subset of $L^N_w(\Omega) \cap E^p_w(\Omega)$ is precompact in $L^q_w(\Omega)$ if $1 \leq q < N$. Consequently, if $N > p$ and $\mathcal{F}$ is a subset of $W^{1,p,w}(\Omega)$ with

$$\|f\|_{L^N_w(\Omega)} \leq C(\|f\|_{L^p_w(\Omega)} + \|\nabla f\|_{E^p_w(\Omega)}) \quad \text{for all } f \in \mathcal{F},$$

then any set in $\mathcal{F}$ that is bounded in $W^{1,p,w}(\Omega)$ is precompact in $L^q_w(\Omega)$ for $1 \leq q < N$.

If $\Omega$ is a John domain, there exists $N > p$ (N can be $\theta p/(\theta - p)$ for some $\theta > p$ as described after (2.3)) such that $W^{1,p,w}(\Omega)$ is compactly embedded in $L^q_w(\Omega)$ for $1 \leq q < N$. In particular, the embedding of $W^{1,p,w}(\Omega)$ into $L^p_w(\Omega)$ is compact when $w \in A_p(\mathbb{R}^n)$ and $\Omega$ is a John domain.
Remark 2.3. When $w = 1$ and $p < n$, the choices $N = np/(n - p)$ and $\mathcal{S} = W_0^{1,p}(\Omega)$ guarantee (2.4) by the classical Sobolev inequality for functions in $W_0^{1,p}(\Omega)$ (see e.g. [GT, Theorem 7.10]); here $W_0^{1,p}(\Omega)$ denotes the closure in $W^{1,p}(\Omega)$ of the class of Lipschitz functions with compact support in $\Omega$. Consequently, the classical Rellich-Kondrachov theorem giving the compact embedding of $W_0^{1,p}(\Omega)$ in $L^q(\Omega)$ for $1 \leq q < np/(n - p)$ follows as a special case of the first part of Theorem 2.2.

Proof. We will apply Theorem 2.1 with $w = \mu$. Fix $p$ and $w$ with $1 \leq p < \infty$ and $w \in A_p(\mathbb{R}^n)$. By [FKS], there is a constant $C$ such that the weighted Poincaré inequality
\[
||f - f_{D,w}||_{L^p_w(D)} \leq Cr(D)||\nabla f||_{L^p_w(D)}, \quad f \in C^\infty(\Omega),
\]
holds for all Euclidean balls $D \subset \Omega$. Then since $C^\infty(\Omega)$ is dense in $L_w^N(\Omega) \cap E^p_w(\Omega)$ if $1 \leq N < \infty$ (see e.g. [Tur]), by fixing any $\epsilon > 0$ we obtain from Fatou’s lemma that for all balls $D \subset \Omega$ with $Cr(D) \leq \epsilon$,
\[
||f - f_{D,w}||_{L^p_w(D)} \leq \epsilon||\nabla f||_{L^p_w(D)} \quad \text{if} \quad f \in L_w^N(\Omega) \cap E^p_w(\Omega).
\]
The same holds when $N = \infty$ since $L_w^\infty(\Omega) = L^\infty(\Omega) \subset L^p_w(\Omega)$ due to the assumptions $w \in A_p(\mathbb{R}^n)$ and $w(\Omega) < \infty$. With $1 < N \leq \infty$, the first statement of the theorem now follows from Theorem 2.1, and the second statement is a corollary of the first one.

Next, let $\Omega$ be a John domain. Choose $\theta > p$ so that $w$ satisfies (2.3) and define $N = \theta p/(\theta - p)$. Then $N > p$ and by [CW1, Theorem 1.8 (b) or Theorem 4.1],
\[
||f - f_{\Omega,w}||_{L^p_w(\Omega)} \leq C||\nabla f||_{L^p_w(\Omega)}, \quad \forall f \in C^\infty(\Omega).
\]
Again, the inequality remains true for functions in $W^{1,p,w}(\Omega)$ by density and Fatou’s lemma. It is now clear that (2.4) holds, and the last part of the theorem follows. \qed

Our next example involves domains in $\mathbb{R}^n$ which are more restricted. For special $\Omega$, there are values $N > 1$ such that
\[
||f||_{L^N(\Omega)} \leq C(||f||_{L^1(\Omega)} + ||\nabla f||_{L^p(\Omega)}) \quad (2.5)
\]
for all $f \in L^1(\Omega) \cap E^p(\Omega)$. Note that if $\Omega$ has finite Lebesgue measure, then $W^{1,p}(\Omega) \subset L^1(\Omega) \cap E^p(\Omega)$. As we will explain, (2.5) is true for some $N > 1$ if $\Omega$ is an $s$-John domain in $\mathbb{R}^n$ and $1 \leq s < 1 + \frac{p}{n-1}$. Recall that for $1 \leq s < \infty$, a
bounded domain $\Omega \subset \mathbb{R}^n$ is called an $s$-John domain with central point $x' \in \Omega$ if for some constant $c > 0$ and all $x \in \Omega$ with $x \neq x'$, there is a curve $\Gamma : [0, l] \to \Omega$ so that $\Gamma(0) = x, \Gamma(l) = x'$,

$$|\Gamma(t_1) - \Gamma(t_2)| \leq t_2 - t_1 \quad \text{for all } [t_1, t_2] \subset [0, l],$$

and

$$\rho(\Gamma(t), \Omega^c) \geq ct^s \quad \text{for all } t \in [0, l].$$

The terms 1-John domain and John domain are the same. When $\Omega$ is an $s$-John domain for some $s \in [1, 1 + p/(n - 1))$, it is shown in [KM], [CW1], [CW2] that (2.5) holds for all finite $N$ with

$$\frac{1}{N} \geq \frac{s(n - 1) - p + 1}{np} \quad (2.6)$$

and for all $f \in W^{1,p}(\Omega)$ without any support restrictions. Note that the right side of (2.6) is strictly less than $1/p$ for such $s$, and consequently there are values $N > p$ which satisfy (2.6). For $N$ as in (2.6), the global estimate

$$\|f - f_\Omega\|_{L^N(\Omega)} \leq C\|\nabla f\|_{L^p(\Omega)}, \quad f_\Omega = \int_\Omega f(x)dx/|\Omega|, \quad (2.7)$$

is shown to hold if $f \in Lip_{loc}(\Omega)$ in [CW2], and then follows for all $f \in L^1(\Omega) \cap E^p(\Omega)$; see the proof of Theorem 2.4 for related comments. Inequality (2.5) is clearly a consequence of (2.7).

More generally, weighted versions of (2.7) hold for $s$-John domains and lead to weighted compactness results, as we now show. Let $1 \leq p < \infty$, and for real $\alpha$ and $\rho(x, \Omega^c)$ as in (2.2), let $L_{\rho^{\alpha, dx}}^p(\Omega)$ be the class of Lebesgue measurable $f$ on $\Omega$ with

$$\|f\|_{L_{\rho^{\alpha, dx}}^p(\Omega)} = \left(\int_\Omega |f(x)|^p \rho(x, \Omega^c)^\alpha dx\right)^{1/p} < \infty.$$

**Theorem 2.4.** Suppose that $1 \leq s < \infty$ and $\Omega$ is an $s$-John domain in $\mathbb{R}^n$. Let $p, a, b$ satisfy $1 \leq p < \infty, a \geq 0, b \in \mathbb{R}$ and $b - a < p$.

(i) If

$$n + a > s(n - 1 + b) - p + 1, \quad (2.8)$$

then for any $1 \leq q < \infty$ such that

$$\frac{1}{q} > \max \left\{\frac{1}{p} - \frac{1}{n}, \frac{s(n - 1 + b) - p + 1}{(n + a)p}\right\}, \quad (2.9)$$
$L^1_{\rho^a dx}(\Omega) \cap E^p_{\rho^b dx}(\Omega)$ is compactly embedded in $L^q_{\rho^a dx}(\Omega)$.

(ii) If $p > 1$ and

$$n + ap > s(n - 1 + b) - p + 1 \geq n + a,$$

then for any $1 \leq q < \infty$ such that

$$\frac{a}{q} > \max \left\{ \frac{b}{p} - 1, \frac{s(n - 1 + b) - p - n + 1}{p} \right\},$$

$L^1_{\rho^a dx}(\Omega) \cap E^p_{\rho^b dx}(\Omega)$ is compactly embedded in $L^q_{\rho^a dx}(\Omega)$.

**Remark 2.5.**

1. If $a = b = 0$, (2.8) is the same as $s < 1 + \frac{p}{n-1}$. If $a = 0$, (2.10) never holds.

2. The requirement that $b - a < p$ follows from (2.8) and (2.9) by considering the cases $n - 1 + b \geq 0$ and $n - 1 + b < 0$ separately. Hence $b - a < p$ automatically holds in part (i), but it is an assumption in part (ii). Also, (2.10) and (2.11) imply that $q < p$, and consequently that $p > 1$.

3. Conditions (2.8) and (2.9) imply there exists $N \in (p, \infty)$ with

$$\frac{1}{q} > \frac{1}{N} > \max \left\{ \frac{1}{p} - \frac{1}{n}, \frac{s(n - 1 + b) - p + 1}{(n + a)p} \right\}.$$

Conversely, (2.8) holds if there exists $N \in (p, \infty)$ so that (2.12) holds.

4. Assumption (2.11) ensures that there exists $N \in (q, \infty)$ such that (2.11) holds with $q$ replaced by $N$.

**Proof:** This result is also a consequence of Theorem 2.1, but we will deduce it from Theorem 1.1 by using arguments like those in the proofs of Theorems 2.1 and 2.2. Fix $a, b, p, q$ as in the hypothesis and denote $\rho(x) = \rho(x, \Omega^c)$. Choose $w = \rho^a dx$ and note that $w(\Omega) < \infty$ since $a \geq 0$ and $\Omega$ is now bounded. Define

$$\mathcal{X}(\Omega) = \{ g = (g_1, \ldots, g_n) : |g| \in L^p_{\rho^a dx}(\Omega) \}$$

and $||g||_{\mathcal{X}(\Omega)} = ||g||_{L^p_{\rho^a dx}(\Omega)}$. Fix $\epsilon > 0$ and choose a compact set $K \subset \Omega$ with $|\Omega \setminus K|_{\rho^a dx} := \int_{\Omega \setminus K} \rho^a dx < \epsilon$. Also choose $\delta'_\epsilon$ with $0 < \delta'_\epsilon < \rho(K, \Omega^c)$, where $\rho(K, \Omega^c)$ is the Euclidean distance between $K$ and $\Omega^c$. 
If $D$ is a Euclidean ball with center $x_D \in K$ and $r(D) < \frac{1}{2} \delta'$, then $2D \subset \Omega$ and $\rho(x)$ is essentially constant on $D$; in fact, for such $D$,

$$\frac{1}{2} \rho(x_D) \leq \rho(x) \leq \frac{3}{2} \rho(x_D), \quad x \in D.$$ 

We claim that for such $D$, the simple unweighted Poincaré estimate

$$\| f - f_D \|_{L^p(D)} \leq Cr(D) \| \nabla f \|_{L^p(D)}, \quad f \in Lip_{loc}(\Omega),$$

where $f_D = f_{D, dx}$, implies that for $f \in Lip_{loc}(\Omega)$,

$$\| f - f_{D, \rho^a dx} \|_{L^p_{\rho^a dx}(D)} \leq \tilde{C} \left( r(D) \frac{a-b}{p} + \text{diam}(\Omega) \frac{a-b}{p} \right) r(D) \| \nabla f \|_{L^p_{\rho^a dx}(D)}, \quad (2.13)$$

where $f_{D, \rho^a dx} = \int_D f \rho^a dx / \int_D \rho^a dx$ and $\tilde{C}$ depends on $C, a, b$ but is independent of $D, f$. To show this, first note that for such $D$, since $\rho \sim \rho(x_D)$ on $D$, the simple Poincaré estimate immediately gives

$$\| f - f_D \|_{\rho^a dx(D)} \leq \tilde{C} \rho(x_D) \frac{a-b}{p} r(D) \| \nabla f \|_{L^p_{\rho^a dx}(D)}, \quad f \in Lip_{loc}(\Omega),$$

and then a similar estimate with $f_D$ replaced by $f_{D, \rho^a dx}$ follows by standard arguments. Clearly (2.13) will now follow if we show that

$$\rho(x_D) \frac{a-b}{p} \leq r(D) \frac{a-b}{p} + \text{diam}(\Omega) \frac{a-b}{p} \quad \text{for such } D.$$ 

However, this is clear since $r(D) \leq \rho(x_D) \leq \text{diam}(\Omega)$ for $D$ as above, and (2.13) is proved.

We can now apply the weighted density result of [H], [HK1] to conclude that (2.13) holds for all $f \in L^1_{\rho^a dx}(\Omega) \cap E^p_{\rho^a dx}(\Omega)$ and all balls $D$ with $x_D \in K$ and $r(D) < \frac{1}{2} \delta'$.

Recall that $\frac{a-b}{p} + 1 > 0$. Thus there exists $r_\epsilon$ with $0 < r_\epsilon < \frac{1}{2} \delta'$ and

$$\tilde{C} \left( r_\epsilon \frac{a-b}{p} + \text{diam}(\Omega) \frac{a-b}{p} \right) r_\epsilon < \epsilon.$$

Let $\Sigma$ and $\Sigma_0$ be as in the proof of Theorem 2.1, and let $\{E_\ell\}_\ell = \{F_\ell\}_\ell$ be the triples of balls in a maximal collection of pairwise disjoint balls centered in $K$ with radius $\frac{1}{4} r_\epsilon$. Then (2.13) and the choice of $r_\epsilon$ give the desired version of (1.4), namely

$$\| f - f_{D, \rho^a dx} \|_{L^p_{\rho^a dx}(D)} \leq \epsilon \| \nabla f \|_{L^p_{\rho^a dx}(D)}$$
for $D = E_t$ and $f \in L^1_{p^d} d\Omega \cap E^p_{q^d} d\Omega$. Next, use the last two parts of Remark 2.5 to choose $N \in (q, \infty)$ so that either (2.9) or (2.11) holds with $q$ there replaced by $N$. Every $f \in L^1_{p^d} d\Omega \cap E^p_{q^d} d\Omega$ then satisfies the global Poincaré estimate

$$
||f - f_{\Omega, \rho^d}||_{L^N_{p^d} d\Omega} \leq C||\nabla f||_{L^p_{q^d} d\Omega}, \quad f \in L^1_{p^d} d\Omega \cap E^p_{q^d} d\Omega,
$$

where $f_{\Omega, \rho^d} = \int_{\Omega} f \rho^d d\Omega / \int_{\Omega} \rho^d d\Omega$. In fact, under the hypothesis of Theorem 2.4, this is proved for $f \in Lip_{loc}(\Omega) \cap L^1_{p^d} d\Omega \cap E^p_{q^d} d\Omega$ in [CW2] for example, and then follows for all $f \in L^1_{p^d} d\Omega \cap E^p_{q^d} d\Omega$ by the density result of [H], [HK1] and Fatou’s lemma. By (2.14),

$$
||f||_{L^N_{p^d} d\Omega} \leq C||f||_{L^1_{p^d} d\Omega} + C||\nabla f||_{L^p_{q^d} d\Omega},
$$

for the same class of $f$. The remaining details of the proof are left to the reader. □

In passing, we mention that the role played by the distance function $\rho(x, \Omega^c)$ in Theorem 2.4 can instead be played by

$$
\rho_0(x) = \inf\{|x - y| : y \in \Omega_0\}, \quad x \in \Omega,
$$

for certain $\Omega_0 \subset \Omega^c$; see [CW2, Theorem 1.6] for a description of such $\Omega_0$ and the required Poincaré estimate, and note that the density result in [HK1] holds for positive continuous weights.

### 3 Applications in the Degenerate Case

In this section, $\Omega$ denotes a fixed open set in $\mathbb{R}^n$, possibly unbounded. For $(x, \xi) \in \Omega \times \mathbb{R}^n$, we consider a nonnegative quadratic form $\xi^t Q(x) \xi$ which may degenerate, i.e., which may vanish for some $\xi \neq 0$. Such quadratic forms occur naturally in the context of subelliptic equations and give rise to degenerate Sobolev spaces as discussed below. Our goal is to apply Theorem 1.1 to obtain compact embedding of these degenerate spaces into Lebesgue spaces related to the gain in integrability provided by Poincaré-Sobolev inequalities. The framework that we will use contains the subelliptic one developed in [SW1, 2], where regularity theory for weak solutions of linear subelliptic equations of second order in divergence form is studied.
3.1 Standing Assumptions

We now list some notation and assumptions that will be in force everywhere in §3 even when not explicitly mentioned.

**Definition 3.1.** A function $d$ is called a finite symmetric quasimetric (or simply a quasimetric) on $\Omega$ if $d : \Omega \times \Omega \to [0, \infty)$ and there is a constant $\kappa \geq 1$ such that for all $x, y, z \in \Omega$,

$$
\begin{align*}
d(x, y) &= d(y, x), \\
d(x, y) &= 0 \iff x = y, \text{ and} \\
d(x, y) &\leq \kappa[d(x, z) + d(z, y)]. \\
\end{align*}
$$

(3.1)

If $d$ is a quasimetric on $\Omega$, we refer to the pair $(\Omega, d)$ as a quasimetric space. In some applications, $d$ is closely related to $Q(x)$. For example, $d$ is sometimes chosen to be the Carnot-Carathéodory control metric related to $Q$; cf. [SW1].

Given $x \in \Omega$, $r > 0$, and a quasimetric $d$, the subset of $\Omega$ defined by

$$
B_r(x) = \{ y \in \Omega : d(x, y) < r \}
$$

will be called the quasimetric $d$-ball centered at $x$ of radius $r$. Note that every $d$-ball $B = B_r(x)$ satisfies $B \subset \Omega$ by definition.

It is sometimes possible, and desirable in case the boundary of $\Omega$ is rough, to be able to work only with $d$-balls that are deep inside $\Omega$ in the sense that their Euclidean closures $\overline{B}$ lie in $\Omega$. See part (ii) of Remark 3.6 for comments about being able to use such balls.

Recall that $D_s(x)$ denotes the ordinary Euclidean ball of radius $s$ centered at $x$. We always assume that $d$ is related as follows to the standard Euclidean metric:

$$
\forall x \in \Omega \text{ and } r > 0, \exists s = s(x, r) > 0 \text{ so that } D_s(x) \subset B_r(x). \\
$$

(3.2)

**Remark 3.2.** Condition (3.2) is clearly true if $d$-balls are open, and it is weaker than the well-known condition of C. Fefferman and Phong stating that for each compact $K \subset \Omega$, there are constants $\beta, r_0 > 0$ such that $D_{r,\beta}(x) \subset B_r(x)$ for all $x \in K$ and $0 < r < r_0$.

Throughout §3, $Q(x)$ denotes a fixed Lebesgue measurable $n \times n$ nonnegative symmetric matrix on $\Omega$ and we assume that every $d$-ball $B$ centered in $\Omega$ is Lebesgue measurable. We will deal with three locally finite measures $\nu, \nu, \mu$ on the Lebesgue measurable subsets of $\Omega$, each with a particular role. In §3.3, where
only global results are developed, we will assume \( w(\Omega) < \infty \) but this assumption is not required for the local results of §3.4. The measure \( \mu \) is assumed to be absolutely continuous with respect to Lebesgue measure; the comment following (3.4) explains why this assumption is natural. In §3, we sometimes assume that \( w \) is absolutely continuous with respect to \( \nu \), but we drop this assumption completely in the Appendix.

We do not require the existence of a doubling measure for the collection of \( d \)-balls, but we always assume that \( (\Omega, d) \) satisfies the weaker local geometric doubling property given in the next definition; see [HyM] for a global version.

**Definition 3.3.** A quasimetric space \((\Omega, d)\) satisfies the local geometric doubling condition if for every compact \( K \subset \Omega \), there exists \( \delta' = \delta'(K) > 0 \) such that for all \( x \in K \) and all \( 0 < r' < r < \delta' \), the number of disjoint \( d \)-balls of radius \( r' \) contained in \( B_r(x) \) is at most a constant \( C_{r/r'} \) depending on \( r/r' \) but not on \( K \).

### 3.2 Degenerate Sobolev Spaces \( W_{\nu,\mu}^{1,p}(\Omega, Q) \), \( W_{\nu,\mu,0}^{1,p}(\Omega, Q) \)

We will define weighted degenerate Sobolev spaces by using an approach like the one in [SW2] for the unweighted case. We first define an appropriate space of vectors, including vectors which will eventually play the role of gradients, where size is measured relative to the nonnegative quadratic form

\[
Q(x, \xi) = \xi' Q(x) \xi, \quad (x, \xi) \in \Omega \times \mathbb{R}^n.
\]

For \( 1 \leq p < \infty \), consider the collection of measurable \( \mathbb{R}^n \)-valued functions \( \vec{g}(x) = (g_1(x), \ldots, g_n(x)) \) satisfying

\[
||\vec{g}||_{L^p_{\nu,\mu}(\Omega)} = \left\{ \int_{\Omega} Q(x, \vec{g}(x))^{\frac{p}{2}} d\mu \right\}^{\frac{1}{p}} = \left\{ \int_{\Omega} |\sqrt{Q(x)} \vec{g}(x)|^p d\mu \right\}^{\frac{1}{p}} < \infty. \tag{3.3}
\]

We identify any two functions \( \vec{g}, \vec{h} \) in the collection for which \( ||\vec{g} - \vec{h}||_{L^p_{\nu,\mu}(\Omega)} = 0 \). Then (3.3) defines a norm on the resulting space of equivalence classes. The form-weighted space \( \mathcal{L}^p_{\mu}(\Omega, Q) \) is defined to be the collection of these equivalence classes, with norm (3.3). By using methods similar to those in [SW2], it follows that \( \mathcal{L}^2_{\mu}(\Omega, Q) \) is a Hilbert space and \( \mathcal{L}^p_{\mu}(\Omega, Q) \) is a Banach space for \( 1 \leq p < \infty \).

Now consider the (possibly infinite) norm on \( \text{Lip}_{\text{loc}}(\Omega) \) defined by

\[
||f||_{W_{\nu,\mu}^{1,p}(\Omega, Q)} = ||f||_{L^p_{\nu}(\Omega)} + ||\nabla f||_{\mathcal{L}^p_{\mu}(\Omega, Q)}. \tag{3.4}
\]
We comment here that our standing assumption that \( \mu(Z) = 0 \) when \( Z \) has Lebesgue measure 0 assures that \( ||\nabla f||_{L^p(\Omega)} \) is well-defined if \( f \in Lip_{\text{loc}}(\Omega) \); in fact, for such \( f \), the Rademacher-Stepanov theorem implies that \( \nabla f \) exists a.e. in \( \Omega \) with respect to Lebesgue measure.

**Definition 3.4.** Let \( 1 \leq p < \infty \).

1. The degenerate Sobolev space \( W_{1,p}^{1, \nu, \mu}(\Omega, Q) \) is the completion under the norm (3.4) of the set
   \[
   Lip_Q(\Omega) = Lip_Q,_{p, \nu, \mu}(\Omega) = \{ f \in Lip_{\text{loc}}(\Omega) : ||f||_{W_{1,p}^{1, \nu, \mu}(\Omega, Q)} < \infty \}.
   \]

2. The degenerate Sobolev space \( W_{1,p}^{1, \nu, \mu, 0}(\Omega, Q) \) is the completion under the norm (3.4) of the set \( Lip_Q,_{p, 0}(\Omega) = Lip_0(\Omega) \cap Lip_Q, p(\Omega) \), where \( Lip_0(\Omega) \) denotes the collection of Lipschitz functions with compact support in \( \Omega \). If \( Q \in L^{p/2}_{\text{loc}}(\Omega) \), then \( Lip_Q,_{p, 0}(\Omega) = Lip_0(\Omega) \) since \( \nu \) and \( \mu \) are locally finite.

We now make some comments about \( W_{1,p}^{1, \nu, \mu}(\Omega, Q) \), most of which have analogues for \( W_{1,p}^{1, \nu, \mu, 0}(\Omega, Q) \). By definition, \( W_{1,p}^{1, \nu, \mu}(\Omega, Q) \) is the Banach space of equivalence classes of Cauchy sequences of \( Lip_Q, p(\Omega) \) functions with respect to the norm (3.4). Given a Cauchy sequence \( \{ f_j \} \) of \( Lip_Q, p(\Omega) \) functions, we denote its equivalence class by \( [\{ f_j \}] \). If \( \{ v_j \} \in [\{ f_j \}] \), then \( \{ v_j \} \) is a Cauchy sequence in \( L^p(\Omega) \) and \( \{ \nabla v_j \} \) is a Cauchy sequence in \( L^p(\Omega, Q) \). Hence, there is a pair \( (f, \vec{g}) \in L^p(\Omega) \times L^p(\Omega, Q) \) so that
   \[
   ||v_j - f||_{L^p(\Omega)} \to 0 \quad \text{and} \quad ||\nabla v_j - \vec{g}||_{L^p(\Omega, Q)} \to 0
   \]
as \( j \to \infty \). The pair \( (f, \vec{g}) \) is uniquely determined by the equivalence class \( [\{ f_j \}] \), i.e., is independent of a particular \( \{ v_j \} \in [\{ f_j \}] \). We will say that \( (f, \vec{g}) \) is represented by \( \{ v_j \} \). We obtain a Banach space isomorphism \( J \) from \( W_{1,p}^{1, \nu, \mu}(\Omega, Q) \) onto a closed subspace \( W_{1,p}^{1, \nu, \mu}(\Omega, Q) \) of \( L^p(\Omega) \times L^p(\Omega) \) by setting
   \[
   J([\{ f_j \}]) = (f, \vec{g}).
   \]
We will often not distinguish between \( W_{1,p}^{1, \nu, \mu}(\Omega, Q) \) and \( W_{1,p}^{1, \nu, \mu}(\Omega, Q) \). Similarly, \( W_{1,p}^{1, \nu, \mu, 0}(\Omega, Q) \) will denote the image of \( W_{1,p}^{1, \nu, \mu, 0}(\Omega, Q) \) under \( J \), but we often consider these spaces to be the same.

It is important to think of a typical element of \( W_{1,p}^{1, \nu, \mu}(\Omega, Q) \), or \( W_{1,p}^{1, \nu, \mu}(\Omega, Q) \), as a pair \( (f, \vec{g}) \) as above, and not simply as the first component \( f \). In fact, if
\((f, \vec{g}) \in W^{1,p}_{\nu, \mu}(\Omega, Q)\), the vector \(\vec{g}\) may not be uniquely determined by \(f\); see [FKS, Section 2.1] for a well known example.

If \(f \in \text{Lip}_{\nu, \mu}(\Omega)\), then the pair \((f, \nabla f)\) may be viewed as an element of \(W^{1,p}_{\nu, \mu}(\Omega, Q)\) by identifying it with the equivalence class \([f]\) corresponding to the sequence each of whose entries is \(f\). When viewed as a class, \((f, \nabla f)\) generally contains pairs whose first components are not Lipschitz functions; for example, if \(f \in \text{Lip}_{\nu, \mu}(\Omega)\) and \(F\) is any function with \(F = f\) a.e.-\(\nu\), then \((f, \nabla f) = (F, \nabla f)\) in \(W^{1,p}_{\nu, \mu}(\Omega, Q)\). However, in what follows, when we consider a pair \((f, \nabla f)\) with \(f \in \text{Lip}_{\nu, \mu}(\Omega)\), we will not adopt this point of view. Instead we will identify an \(f \in \text{Lip}_{\nu, \mu}(\Omega)\) with the single pair \((f, \nabla f)\) whose first component is \(f\) (defined everywhere in \(\Omega\)) and whose second component is \(\nabla f\), which exists a.e. with respect to Lebesgue measure by the Rademacher-Stepanov theorem. This convention lets us avoid assuming that \(w\) is absolutely continuous with respect to \(\nu\), written \(w \ll \nu\), in Poincaré-Sobolev estimates for \(\text{Lip}_{\nu, \mu}(\Omega)\) functions. We will reserve the notation \(\mathcal{H}\) for subsets of \(\text{Lip}_{\nu, \mu}(\Omega)\) viewed in this way.

On the other hand, \(W\) will denote various subsets of \(W^{1,p}_{\nu, \mu}(\Omega, Q)\) with elements viewed as equivalence classes. When our hypotheses are phrased in terms of such \(W\), we will assume that \(w \ll \nu\) in order to avoid technical difficulty associated with sets of measure 0; see the comment after (3.18). In the Appendix, we drop the assumption \(w \ll \nu\) altogether.

We will abuse the notation (3.4) by writing

\[
|| (f, \nabla f) ||_{W^{1,p}_{\nu, \mu}(\Omega, Q)} = || f ||_{L^p(\Omega)} + || \nabla f ||_{L^p(\Omega, Q)}, \quad f \in \text{Lip}_{\nu, \mu}(\Omega),
\]

and we extend this to generic \((f, \vec{g}) \in W^{1,p}_{\nu, \mu}(\Omega, Q)\) by writing

\[
|| (f, \vec{g}) ||_{W^{1,p}_{\nu, \mu}(\Omega, Q)} = || f ||_{L^p(\Omega)} + || \vec{g} ||_{L^p(\Omega, Q)}.
\]

### 3.3 Global Compactness Results for Degenerate Spaces

In this section, we state and prove compactness results which apply to the entire set \(\Omega\). Results which are more local are given in §3.4.

In order to apply Theorem 1.1 in this setting, we will use the following version of Poincaré’s inequality for \(d\)-balls.

**Definition 3.5.** Let \(1 \leq p < \infty\), \(\text{Lip}_{\nu, \mu}(\Omega)\) be as in Definition 3.4, and \(\mathcal{H} \subset \text{Lip}_{\nu, \mu}(\Omega)\). We say that the Poincaré property of order \(p\) holds for \(\mathcal{H}\) if there is a constant \(c_0 \geq 1\) so that for every \(\epsilon > 0\) and every compact set \(K \subset \Omega\), there exists
\[ \delta = \delta(\epsilon, K) > 0 \] such that for all \( f \in \mathcal{H} \) and every \( d \)-ball \( B_r(y) \) with \( y \in K \) and \( 0 < r < \delta \),

\[
\left( \int_{B_r(y)} |f - f_{B_r(y),w}|^p \, dw \right)^{\frac{1}{p}} \leq \epsilon \| (f, \nabla f) \|_{W_{1,p}^w(B_{c_r}(y), Q)}.
\] (3.8)

**Remark 3.6.** (i) Inequality (3.8) is not of standard Poincaré form. A more typical form is

\[
\left( \frac{1}{w(B_r(y))} \int_{B_r(y)} |f - f_{B_r(y),w}|^p \, dw \right)^{\frac{1}{p}} \leq Cr \left( \frac{1}{\mu(B_{c_r}(y))} \int_{B_{c_r}(y)} |\sqrt{Q} \nabla f|^{p} \, d\mu \right)^{\frac{1}{p}}.
\] (3.9)

In [SW1, 2] and [R1], the unweighted version of (3.9) with \( p = 2 \) is used. Let \( \rho(x, \partial \Omega) \) and \( \rho(E, \partial \Omega) \) be as in (2.2). In [SW2], the unweighted form of (3.9) with \( p = 2 \) is assumed for all \( f \in \text{Lip}_{Q,2}(\Omega) \) and all \( B_r(y) \) with \( y \in \Omega \) and \( 0 < r < \delta_0 \rho(y, \partial \Omega) \) for some \( \delta_0 \in (0,1) \) independent of \( y, r \). If \( K \) is a compact set in \( \Omega \), this version would then hold for all \( B_r(y) \) with \( y \in K \) and \( 0 < r < \delta_0 \rho(K, \partial \Omega) \). For general \( p, w \) and \( \mu \), if for every compact \( K \subset \Omega \), (3.9) is valid for all \( B_r(y) \) with \( y \in K \) and \( 0 < r < \delta_0 \rho(K, \partial \Omega) \), then (3.8) follows easily provided

\[
\lim_{r \to 0} \left\{ \sup_{y \in K} r^p \frac{w(B_r(y))}{\mu(B_{c_r}(y))} \right\} = 0
\] (3.10)

for every compact \( K \subset \Omega \). Note that (3.10) automatically holds if \( w = \mu \).

If both (3.9) and (3.10) hold, then (3.8) is true for any choice of \( \nu \). In this situation, one can pick \( \nu = w \) in order to avoid technicalities encountered below when \( w \) is not absolutely continuous with respect to \( \nu \).

(ii) Especially when \( \partial \Omega \) is rough, it is simplest to deal only with \( d \)-balls \( B \) which stay away from \( \partial \Omega \), i.e., which satisfy

\[ \overline{B} \subset \Omega. \] (3.11)

We can always assume this for the balls in (3.8) if the converse of (3.2) is also true, namely if

\[
\forall x \in \Omega \text{ and } r > 0, \exists s = s(r, x) > 0 \text{ such that } B_s(x) \subset D_r(x).
\] (3.12)
To see why, let us first show that given a compact set $K$ and an open set $G$ with $K \subset G \subset \Omega$, there exists $t > 0$ so that $B_t(y) \subset G$ for all $y \in K$. Indeed, for such $K$ and $G$, let $t' = \frac{1}{2} \rho(K,G^c)$. By (3.12), for each $x \in K$ there exists $r(x) > 0$ so that $B_r(x) \subset D_r(x)$. Further, by (3.2), there exists $s(x) > 0$ so that $D_{s(x)}(x) \subset B_r(x)/(2\kappa)(x)$, where $\kappa$ is as in (3.1). Since $K$ is compact, we may choose finite collections $\{B_{r_i/(2\kappa)}(x_i)\}$ and $\{D_{s_i}(x_i)\}$ with $x_i \in K$, $r_i = r(x_i)$, $s_i = s(x_i)$, and $K \subset \bigcup D_{s_i}(x_i) \subset \bigcup B_{r_i/(2\kappa)}(x_i)$. Now set $t = \min\{r_i/(2\kappa)\}$. Let $y \in K$ and choose $i$ such that $y \in B_{r_i/(2\kappa)}(x_i)$. By (3.1), $B_t(y) \subset B_{r_i}(x_i)$ and consequently $B_t(y) \subset D_{r_i}(x_i)$. Since $D_{r_i}(x_i) \subset G$, we obtain $B_t(y) \subset G$ for every $y \in K$, as desired. In particular, $B_t(y) \subset \Omega$ for all $y \in K$. Since the validity of (3.8) for some $\delta = \delta(\epsilon,K)$ implies its validity for $\min\{\delta,t\}$, it follows that we may assume (3.11) for every $B_t(y)$ in (3.8) when (3.12) holds. Similarly, since the constant $c_0$ in (3.8) is independent of $K$, we may assume as well that every $B_{\alpha r}(y)$ in (3.8) has closure in $\Omega$.

(iii) We can often slightly weaken the assumption in Definition 3.5 that $K$ is an arbitrary compact set in $\Omega$. For example, in our results where $w(\Omega) < \infty$, it is generally enough to assume that for each $\epsilon > 0$, there is a particular compact $K$ with $w(\Omega \setminus K) < \epsilon$ such that (3.8) holds. However, in §3.4, where we do not assume $w(\Omega) < \infty$, it is convenient to keep the hypothesis that $K$ is arbitrary.

Given a set $\mathcal{H} \subset Lip_{Q,p}(\Omega)$, define

$$
\hat{\mathcal{H}} = \{f : \text{there exists } \{f^j\} \subset \mathcal{H} \text{ with } f^j \to f \text{ a.e.-}w\}. 
$$

(3.13)

It will be useful later to note that if $\mathcal{H}$ is bounded in $L^N_w(\Omega)$ for some $N$, then $\hat{\mathcal{H}}$ is also bounded in $L^N_w(\Omega)$ by Fatou’s lemma; in particular, every $f \in \mathcal{H}$ then belongs to $L^N_w(\Omega)$. See (3.15) for a relationship between $\hat{\mathcal{H}}$ and the closure of $\mathcal{H}$ in $W^{1,p}_w(\Omega,Q)$ in case $w << \nu$.

We now state our simplest global result. Its proof is given after Corollary 3.11.

**Theorem 3.7.** Let the assumptions of §3.1 hold, $w(\Omega) < \infty$, $1 \leq p < \infty$, $1 < N \leq \infty$ and $\mathcal{H} \subset Lip_{Q,p}(\Omega)$. Suppose that the Poincaré property of order $p$ in Definition 3.5 holds for $\mathcal{H}$ and that

$$
\sup_{f \in \hat{\mathcal{H}}} \{|f|_{L^p_w(\Omega)} + |f|_{L^p_\nu(\Omega)} + |\nabla f|_{L^p_\nu(\Omega,Q)}\} < \infty.
$$

(3.14)

Then any sequence $\{f_k\} \subset \hat{\mathcal{H}}$ has a subsequence that converges in $L^q_w(\Omega)$ norm for every $1 \leq q < N$ to a function belonging to $L^N_w(\Omega)$.  

Let $\mathcal{H} \subset \text{Lip}_{Q,p}(\Omega)$ and $\hat{\mathcal{H}}$ be as in (3.13). We reserve the notation $\overline{\mathcal{H}}$ for the closure of $\mathcal{H}$ in $W^{1,p}_{\nu,\mu}(\Omega)$, i.e., for the closure of the collection $\{(f, \nabla f) : f \in \mathcal{H}\}$ with respect to the norm (3.6). Elements of $\overline{\mathcal{H}}$ are viewed as equivalence classes.

If $w \ll \nu$, then

$$\{f : \text{there exists } \vec{g} \text{ such that } (f, \vec{g}) \in \overline{\mathcal{H}}\} \subset \hat{\mathcal{H}}.$$  \hspace{1cm} (3.15)

Indeed, if $(f, \vec{g}) \in \overline{\mathcal{H}}$, there is a sequence $\{f_j\} \subset \mathcal{H}$ such that $(f_j, \nabla f_j) \to (f, \vec{g})$ in $W^{1,p}_{\nu,\mu}(\Omega)$ norm, and consequently $f_j \to f$ in $L^p_{\nu}(\Omega)$. By using a subsequence, we may assume that $f_j \to f$ pointwise a.e.-$\nu$, and hence by absolute continuity that $f_j \to f$ pointwise a.e.-$w$. This proves (3.15). In fact, it can be verified by using Egorov’s theorem that

$$\{f : \text{there exists } \{(f_j, \vec{g}_j)\} \subset \mathcal{H} \text{ with } f_j \to f \text{ a.e.-}w \} \subset \hat{\mathcal{H}}.$$  \hspace{1cm} (3.16)

Theorem 3.7 and (3.15) immediately imply the following corollary.

**Corollary 3.8.** Let the assumptions of §3.1 hold, $w(\Omega) < \infty$ and $w \ll \nu$. Let $1 \leq p < \infty$, $1 < N \leq \infty$, $\mathcal{H} \subset \text{Lip}_{Q,p}(\Omega)$ and $\overline{\mathcal{H}}$ be the closure of $\mathcal{H}$ in $W^{1,p}_{\nu,\mu}(\Omega, Q)$. Suppose that the Poincaré property of order $p$ in Definition 3.5 holds for $\mathcal{H}$ and that

$$\sup_{f \in \mathcal{H}} \left\{ ||f||_{L^p_w(\Omega)} + ||(f, \nabla f)||_{W^{1,p}_{\nu,\mu}(\Omega, Q)} \right\} < \infty. \hspace{1cm} (3.17)$$

Then any sequence $\{f_k\}$ in

$$\{f : \text{there exists } \vec{g} \text{ such that } (f, \vec{g}) \in \overline{\mathcal{H}}\}$$

has a subsequence that converges in $L^q_w(\Omega)$ norm for $1 \leq q < N$ to a function that belongs to $L^N_w(\Omega)$.

**Remark 3.9.** Corollary 3.8 may be thought of as an analogue in the degenerate setting of the Rellich-Kondrachov theorem since it contains this classical result as a special case. To see why, set $Q(x) = \text{Id}$ and $w = \nu = \mu$ to be Lebesgue measure. Then, given a bounded sequence $\{(f_k, \vec{g}_k)\} \subset W^{1,p}_0(\Omega) = W^{1,p}_{\text{dx},\text{dx},0}(\Omega, Q)$ we may choose $\{f_{kj}\} \subset \text{Lip}_0(\Omega)$ with $(f_{kj}, \nabla f_{kj}) \to (f, \vec{g})$ in $W^{1,p}(\Omega)$ norm. Thus, setting $\mathcal{H} = \{f_{kj}\}_{k \in \mathbb{N}, j > J_k}$ where each $J_k$ is chosen sufficiently large to preserve boundedness, the classical Sobolev inequality gives (3.17) with $N = np/(n - p)$ for $1 \leq p < n$. The Rellich-Kondrachov theorem now follows from Corollary 3.8.
We next mention analogues of these results when $\mathcal{H}$ is replaced by a set $\mathcal{W} \subset W^{1,p}_{\nu,\mu}(\Omega, Q)$ with elements viewed as equivalence classes, assuming that $w << \nu$.

We then modify Definition 3.5 by replacing (3.8) with the analogous estimate

$$\left( \int_{B_r(y)} |f - f_{B_r(y),w}|^pdw \right)^{\frac{1}{p}} \leq \epsilon \|(f,\tilde{g})\|_{W^{1,p}_{\nu,\mu}(B_{r^0(y),Q})}$$

if $(f,\tilde{g}) \in \mathcal{W}$. (3.18)

The assumption $w << \nu$ guarantees that the left side of (3.18) does not change when the first component of a pair is arbitrarily altered in a set of $\nu$-measure zero.

If Poincaré’s inequality is known to hold for subsets of Lipschitz functions in the form (3.8), it can often be extended by approximation to the similar form (3.18) for subsets of $W^{1,p}_{\nu,\mu}(\Omega, Q)$. Indeed, let us show without using weak convergence that if $w << \nu$ and the Radon-Nikodym derivative $dw/d\nu \in L^p_{\nu,loc}(\Omega)$, then (3.18) holds if $\mathcal{W} = W^{1,p}_{\nu,\mu}(\Omega, Q)$ and we choose $\{f_j\} \subset Lip_{Q,p}(\Omega)$ with $(f_j, \nabla f_j) \to (f,\tilde{g})$ in $W^{1,p}_{\nu,\mu}(\Omega, Q)$, then for any ball $B$, since $f_j \to f$ in $L^p_{\nu}(\Omega)$, we have

$$(f_j)_{B,w} = \frac{1}{w(B)} \int_B f_j \frac{dw}{d\nu} d\nu \to \frac{1}{w(B)} \int_B f \frac{dw}{d\nu} d\nu = f_{B,w}.$$  

Of course we may also assume that $f_j \to f$ a.e.-$w$ by selecting a subsequence of $\{f_j\}$ which converges to $f$ a.e.-$\nu$. The same argument shows that if (3.18) holds for all pairs in any set $\mathcal{W} \subset W^{1,p}_{\nu,\mu}(\Omega, Q)$, then it also holds for pairs in the closure $\overline{\mathcal{W}}$ of $\mathcal{W}$ in $W^{1,p}_{\nu,\mu}(\Omega, Q)$. Moreover, if all balls $B$ in question satisfy $\overline{B} \subset \Omega$ (cf. (3.11)), then the assumption can clearly be weakened to $dw/d\nu \in L^p_{\nu,loc}(\Omega)$. As we observed in Remark 3.6(ii), the balls in (3.8) can be assumed to satisfy (3.11) provided (3.12) is true.

Analogues of Theorem 3.7 and Corollary 3.8 for a set $\mathcal{W} \subset W^{1,p}_{\nu,\mu}(\Omega, Q)$ are given in the next result, which also includes the Rellich-Kondrachov theorem as a special case.

**Theorem 3.10.** Let the assumptions of §3.1 hold, $w(\Omega) < \infty$ and $w << \nu$. Let $1 \leq p < \infty$, $1 < N \leq \infty$ and $\mathcal{W} \subset W^{1,p}_{\nu,\mu}(\Omega, Q)$. Suppose that the Poincaré property in Definition 3.5 holds, but in the modified form given in (3.18), and that

$$\sup_{(f,\tilde{g}) \in \mathcal{W}} \left\{ \|f\|_{L^p_{\nu}(\Omega)} + \|(f,\tilde{g})\|_{W^{1,p}_{\nu,\mu}(\Omega, Q)} \right\} < \infty.$$  

(3.19)
Let
\[ \mathcal{W} = \{ f : \text{there exists } \{(f^j, g^j)\} \subset \mathcal{W} \text{ with } f^j \to f \text{ a.e.-}w \}. \]
Then any sequence in \( \mathcal{W} \) has a subsequence that converges in \( L^q_w(\Omega) \) norm for every \( 1 \leq q < N \) to a function belonging to \( L^N_w(\Omega) \). In particular, if \( \overline{\mathcal{W}} \) denotes the closure of \( \mathcal{W} \) in \( W^{1,p}_{\nu,\mu}(\Omega,Q) \), then the same is true for any sequence in
\[ \{ f : \text{there exists } \overline{g} \text{ such that } (f, \overline{g}) \in \overline{\mathcal{W}} \}. \]

As a corollary, we obtain a result for arbitrary sequences \( \{(f_k, g_k)\} \) which are bounded in \( W^{1,p}_{\nu,\mu}(\Omega,Q) \) and whose first components \( \{f_k\} \) are bounded in \( L^N_w(\Omega) \).

**Corollary 3.11.** Let the assumptions of §3.1 hold, \( w(\Omega) < \infty, w \ll \nu, 1 \leq p < \infty \) and \( 1 < N \leq \infty \). Suppose that the Poincaré property of order \( p \) in Definition 3.5 holds for all of \( W^{1,p}_{\nu,\mu}(\Omega,Q) \), i.e., Definition 3.5 holds with (3.8) replaced by (3.18) for \( W = W^{1,p}_{\nu,\mu}(\Omega,Q) \). Then if \( \{ (f_k, g_k) \} \) is any sequence in \( W^{1,p}_{\nu,\mu}(\Omega,Q) \) such that
\[ \sup_k \left[ ||f_k||_{L^q_w(\Omega)} + ||(f_k, g_k)||_{W^{1,p}_{\nu,\mu}(\Omega,Q)} \right] < \infty, \]
there is a subsequence of \( \{f_k\} \) that converges in \( L^q_w(\Omega) \) norm for \( 1 \leq q < N \) to a function belonging to \( L^N_w(\Omega) \). If in addition \( dw/d\nu \in L^{p'}(\Omega), 1/p + 1/p' = 1 \), the conclusion remains valid if the Poincaré property holds just for \( \text{Lip}_{Q,p}(\Omega) \).

In fact, the first conclusion in Corollary 3.11 follows by applying Theorem 3.10 with \( \mathcal{W} \) chosen to be the specific sequence \( \{(f_k, g_k)\}_k \) in question, and the second statement follows from the first one and our observation above that (3.18) holds with \( \mathcal{W} = W^{1,p}_{\nu,\mu}(\Omega,Q) \) if \( dw/d\nu \in L^{p'}(\Omega), 1/p + 1/p' = 1 \), and if (3.8) holds with \( \mathcal{H} = \text{Lip}_{Q,p}(\Omega) \).

**Proofs of Theorems 3.7 and 3.10.** We will concentrate on the proof of Theorem 3.7. The proof of Theorem 3.10 is similar and omitted. We begin with a useful covering lemma.

**Lemma 3.12.** Let the assumptions of §3.1 hold and \( w(\Omega) < \infty \). Fix \( p \in [1, \infty) \) and a set \( \mathcal{H} \subset \text{Lip}_{Q,p}(\Omega) \). Suppose the Poincaré property of order \( p \) in Definition 3.5 holds for \( \mathcal{H} \), and let \( \kappa \) be as in (3.1) and \( c_0 \) be as in (3.8). Then for every \( \epsilon > 0 \), there are positive constants \( r = r(\epsilon, \kappa, c_0), M = M(\kappa, c_0) \) and a finite
collection \( \{B_r(y_k)\}_k \) of \( d \)-balls, so that

\[
\begin{align*}
(i) & \quad w(\Omega \setminus \bigcup_k B_r(y_k)) < \varepsilon, \\
(ii) & \quad \sum_k \chi_{B_{c_0 r}(y_k)}(x) \leq M \quad \text{for all } x \in \Omega, \\
(iii) & \quad ||f - f_{B_r(y_k),w}||_{L^p_w(B_r(y_k))} \leq \varepsilon ||(f, \nabla f)||_{W^1,p(B_{c_0 r}(y_k), \mathcal{Q})}
\end{align*}
\]  

for all \( f \in \mathcal{H} \) and all \( k \). Note that \( M \) is independent of \( \varepsilon \).

**Proof:** We first recall the “swallowing” property of \( d \)-balls: There is a constant \( \gamma \geq 1 \) depending only on \( \kappa \) so that if \( x, y \in \Omega \), \( 0 < r_1 \leq r_2 < \infty \) and \( B_{r_1}(x) \cap B_{r_2}(y) \neq \emptyset \), then

\[
B_{r_1}(x) \subset B_{\gamma r_2}(y).
\]  

Indeed, by [CW1, Observation 2.1], \( \gamma \) can be chosen to be \( \kappa + 2\kappa^2 \).

Fix \( \varepsilon > 0 \). Since \( w(\Omega) < \infty \), there is a compact set \( K \subset \Omega \) with \( w(\Omega \setminus K) < \varepsilon \). Let \( \delta' = \delta'(\varepsilon) \) be as in Definition 3.3 for \( K \), and let \( \delta = \delta(\varepsilon) \) be as in (3.8). Fix \( r \) with \( 0 < r < \min\{\delta, \delta'/(c_0 \gamma)\} \) where \( c_0 \) is as in (3.8). For each \( x \in K \), use (3.2) to pick \( s(x, r) > 0 \) so that \( D_{s(x, r)}(x) \subset B_{r/\gamma}(x) \). Since \( K \) is compact, there are finitely many points \( \{x_j\} \) in \( K \) so that \( K \subset \bigcup_j B_{r/\gamma}(x_j) \). Choose a maximal pairwise disjoint subcollection \( \{B_{r/\gamma}(y_k)\} \) of \( \{B_{r/\gamma}(x_j)\} \). We will show that the collection \( \{B_r(y_k)\} \) satisfies (3.20)–(3.22).

To verify (3.20), it is enough to show that \( K \subset \bigcup_k B_r(y_k) \). Let \( y \in K \). Then \( y \in B_{r/\gamma}(x_j) \) for some \( x_j \). If \( x_j = y_k \) for some \( y_k \) then \( y \in B_r(y_k) \). If \( x_j \neq y_k \) for all \( y_k \), there exists \( y_\ell \) so that \( B_{r/\gamma}(y_\ell) \cap B_{r/\gamma}(x_j) \neq \emptyset \). Then \( B_{r/\gamma}(x_j) \subset B_r(y_\ell) \) by (3.23), and \( y \in B_r(y_\ell) \). In either case, we obtain \( y \in \bigcup_k B_r(y_k) \) as desired.

To verify (3.21), suppose that \( \{k_i\}_{i=1}^L \) satisfies \( \cap_i B_{c_0 r}(y_{k_i}) \neq \emptyset \). Then by (3.23), \( B_{c_0 r}(y_{k_i}) \subset B_{c_0 \gamma r}(y_{k_i}) \) for \( 1 \leq i \leq L \). Since \( \gamma, c_0 \geq 1 \), we have \( B_{r/\gamma}(y_k) \subset B_{c_0 r}(y_k) \) for all \( k \), and consequently

\[
\bigcup B_{r/\gamma}(y_k) \subset \bigcup B_{c_0 r}(y_k) \subset B_{c_0 \gamma r}(y_{k_1}).
\]

By construction, \( \{B_{r/\gamma}(y_k)\} \) is pairwise disjoint in \( k \). Since \( 0 < r/\gamma < c_0 \gamma r < \delta' \), the corresponding constant \( C \) in the definition of geometric doubling depends only on \( (c_0 \gamma r)/(r/\gamma) = c_0 \gamma^2 \), i.e., \( C \) depends only on \( \kappa \) and \( c_0 \). Choosing \( M \) to be this constant, we obtain that \( L \leq M \) as desired. The same argument shows that the collection \( \{B_{c_0 r}(y_k)\} \) has the stronger bounded intercept property with the same bound \( M \), i.e., any ball in the collection intersects at most \( M - 1 \) others.
Finally, let us verify (3.22). Recall that $0 < r < \delta$ by construction. Hence (3.8) implies that for each $k$ and all $f \in \mathcal{H}$,

$$
\| f - f_{B_r(y_k),w} \|_{L_w^p(B_r(y_k))} \leq \varepsilon \| (f, \nabla f) \|_{W^1_p(B_{\alpha r}(y_k),Q)},
$$

(3.24)
as required. This completes the proof of Lemma 3.12. \(\Box\)

The proof of Theorem 3.7 will be deduced from Theorem 1.1 by choosing $\mathcal{X}(\Omega) = L^p_\nu(\Omega) \times L^p_\mu(\Omega, Q)$ and considering the product space $B_N, \mathcal{X}(\Omega) = L^N_w(\Omega) \times (L^p_\nu(\Omega) \times L^p_\mu(\Omega, Q))$.

We always choose $\Sigma$ to be the Lebesgue measurable subsets of $\Omega$ and $\Sigma_0 = \{ B_r(x) : r > 0, x \in \Omega \}$. Note that $\mathcal{X}(\Omega)$ and $B_{N,\mathcal{X}(\Omega)}$ are normed linear spaces (even Banach spaces), and the norm in $B_{N,\mathcal{X}(\Omega)}$ is

$$
\|(h, (f, \vec{g}))\|_{B_{N,\mathcal{X}(\Omega)}} = \|h\|_{L^\infty_\nu(\Omega)} + \|f\|_{L^\infty_\mu(\Omega)} + \|\vec{g}\|_{L^\infty_p(\Omega, Q)}.
$$

(3.25)

The roles played in §1 by $g$ and $(f, g)$ are now played by $(f, \vec{g})$ and $(h, (f, \vec{g}))$ respectively.

Let us verify properties (A) and $(B_p)$ in §1 with $\mathcal{X}(\Omega)$ and $\Sigma_0$ chosen as above. To verify (A), fix $B \in \Sigma_0$ and $(f, \vec{g}) \in \mathcal{X}(\Omega)$. Clearly $f \chi_B \in L^p_\nu(\Omega)$ since $f \in L^p_\nu(\Omega)$. Also,

$$
\int_{\Omega} \left( (\vec{g} \chi_B)' Q(\vec{g} \chi_B) \right)^{\frac{p}{2}} d\mu = \int_B \left( \vec{g}' Q(x) \vec{g} \right)^{\frac{p}{2}} d\mu \leq \int_{\Omega} \left( \vec{g}' Q(x) \vec{g} \right)^{\frac{p}{2}} d\mu < \infty.
$$

Thus $(f, \vec{g}) \chi_B \in \mathcal{X}(\Omega)$ and property (A) is proved.

To verify $(B_p)$, let $\{ B_l \}$ be a finite collection of $d$-balls satisfying $\sum_l \chi_{B_l}(x) \leq C_1$ for all $x \in \Omega$. Then if $(f, \vec{g}) \in \mathcal{X}(\Omega)$,

$$
\sum_l \| (f, \vec{g}) \chi_{B_l} \|_{\mathcal{X}(\Omega)}^p = \sum_l \left( \| f \chi_{B_l} \|_{L^p_\nu(\Omega)} + \| \vec{g} \chi_{B_l} \|_{L^p_\mu(\Omega, Q)} \right)^p
$$

$$
\leq 2^{p-1} \sum_l \left( \| f \chi_{B_l} \|_{L^p_\nu(\Omega)}^p + \| \vec{g} \chi_{B_l} \|_{L^p_\mu(\Omega, Q)}^p \right)
$$

$$
= 2^{p-1} \int_{\Omega} |f|^p \left( \sum_l \chi_{B_l} \right)^{\frac{p}{2}} d\nu + \int_{\Omega} \left( \vec{g}' Q \vec{g} \right)^{\frac{p}{2}} \left( \sum_l \chi_{B_l} \right) d\mu
$$
\[
\leq 2^{p-1} C_1 \left( \|f\|_{L_p^p(\Omega)}^p + \|g\|_{L_p^p(\Omega,Q)}^p \right) \leq 2^p C_1 \|(f,\vec{g})\|_{X(\Omega)}^p.
\]
This verifies \((B_p)\) with \(C_2\) chosen to be \(2^p C_1\).

The proof of Theorem 3.7 is now very simple. Let \(H\) satisfy its hypotheses and choose \(S\) in Theorem 1.1 to be the set
\[
S = \{(f,(f,\nabla f)) : f \in H\}.
\]
Note that \(S\) is a bounded subset of \(B_{N,p}^p(\Omega)\) by hypothesis (3.14). Next, in order to choose the pairs \(\{E_\ell,F_\ell\}_\ell\) and verify conditions (i)–(iii) of Theorem 1.1 (see (1.3) and (1.4)), we appeal to Lemma 3.12. Given \(\varepsilon > 0\), let \(\{E_\ell,F_\ell\}_\ell = \{B_{r}(y_k),B_{c_0r}(y_k)\}_k\) where \(\{y_k\}\) and \(r\) are as in Lemma 3.12. Then \(E_\ell,F_\ell \in \Sigma_0\), and conditions (i)–(iii) of Theorem 1.1 are guaranteed by Lemma 3.12. Finally, by noting that the set \(\hat{H}\) defined in (3.13) is the same as the set \(\hat{S}\) defined in (1.5), the conclusion of Theorem 3.7 follows from Theorem 1.1. □

For special domains \(\Omega\) and special choices of \(N\), the boundedness assumption (3.14) (or (3.17)) can be weakened to
\[
\sup_{f \in H} \{\|f\|_{L_p^p(\Omega)} + \|\nabla f\|_{L_p^p(\Omega,Q)}\} = \sup_{f \in H} \|(f,\nabla f)\|_{W^{1,p}_p(\Omega,Q)} < \infty. \quad (3.26)
\]
This is clearly the case for any \(\Omega\) and \(N\) for which there exists a global Sobolev-Poincaré estimate that bounds \(\|f\|_{L_p^p(\Omega)}\) by \(\|(f,\nabla f)\|_{W^{1,p}_p(\Omega,Q)}\) for all \(f \in H\). We now formalize this situation assuming that \(w << \nu\). In the appendix, we consider a case when \(w << \nu\) fails.

The form of the global Sobolev-Poincaré estimate we will use is given in the next definition. It guarantees that (3.14) and (3.26) are the same when \(N = p\sigma\).

**Definition 3.13.** Let \(1 \leq p < \infty\) and \(H \subset Lip_{Q,p}(\Omega)\). Then the global Sobolev property of order \(p\) holds for \(H\) if there are constants \(C > 0\) and \(\sigma > 1\) so that
\[
\|f\|_{L_p^p(\Omega)} \leq C\|(f,\nabla f)\|_{W^{1,p}_p(\Omega,Q)} \quad \text{for all } f \in H. \quad (3.27)
\]
If \(w << \nu\), then (3.27) extends to \((f,\vec{g}) \in \overline{H}\). In fact, let \((f,\vec{g}) \in \overline{H}\) and choose \(\{f_j\} \subset H\) with \((f_j,\nabla f_j) \to (f,\vec{g})\) in \(W^{1,p}_p(\Omega,Q)\). Then \(f_j \to f\) in \(L_p^p(\Omega)\) norm, and by choosing a subsequence we may assume that \(f_j \to f\) a.e.-\(\nu\). Hence \(f_j \to f\) a.e.-\(w\) because \(w << \nu\). Since each \(f_j\) satisfies (3.27), it follows that
\[
\|f\|_{L_p^p(\Omega)} \leq C\|(f,\vec{g})\|_{W^{1,p}_p(\Omega,Q)} \quad \text{if } (f,\vec{g}) \in \overline{H}. \quad (3.28)
\]
Under the same assumptions, namely that Definition 3.13 holds for a set \( H \subset \text{Lip}_{Q,p}(\Omega) \) and that \( w << \nu \), the same sequence \( \{f_j\} \) as above is also bounded in \( L^p_w(\Omega) \) norm and so satisfies \( (f_j)_{E,w} \to f_{E,w} \) for measurable \( E \) by the same weak convergence argument given after the statement of Theorem 1.1. Hence the Poincaré estimate in Definition 3.5 also extends to \( H \) in the same form as (3.18), with \( \mathcal{W} \) there replaced by \( \overline{\mathcal{H}} \), i.e.,

\[
\left( \int_{B_r(y)} |f - f_{B_r(y),w}|^p \, dw \right)^{\frac{1}{p}} \leq \epsilon \| (f, \vec{g}) \|_{W^{1,p}_w(B_{qr}(y),Q)} \quad \text{if } (f, \vec{g}) \in \overline{\mathcal{H}}. \tag{3.29}
\]

Hence, we immediately obtain the next result by choosing \( \mathcal{W} = \overline{\mathcal{H}} \) and \( N = p\sigma \) in Theorem 3.10.

**Theorem 3.14.** Let the assumptions of §3.1 hold, \( w(\Omega) < \infty \) and \( w << \nu \). Fix \( p \in [1, \infty) \) and a set \( H \subset \text{Lip}_{Q,p}(\Omega) \). Suppose the Poincaré and global Sobolev properties of order \( p \) in Definitions 3.5 and 3.13 hold for \( H \), and let \( \sigma \) be as in (3.27). If \( \{(f_k, \vec{g}_k)\} \) is a sequence in \( \overline{\mathcal{H}} \) with

\[
\sup_k \|(f_k, \vec{g}_k)\|_{W^{1,p}_w(\Omega, Q)} < \infty, \tag{3.30}
\]

then \( \{f_k\} \) has a subsequence which converges in \( L^q_w(\Omega) \) for \( 1 \leq q < p\sigma \), and the limit of the subsequence belongs to \( L^p_w(\Omega) \).

A result for the entire space \( W^{1,p}_{\nu,\mu}(\Omega, Q) \) follows by choosing \( \mathcal{H} = \text{Lip}_{Q,p}(\Omega) \) in Theorem 3.14 or Corollary 3.8:

**Corollary 3.15.** Suppose that the hypotheses of Theorem 3.14 hold for \( \mathcal{H} = \text{Lip}_{Q,p}(\Omega) \). If \( \{(f_k, \vec{g}_k)\} \subset W^{1,p}_{\nu,\mu}(\Omega, Q) \) and (3.30) is true then \( \{f_k\} \) has a subsequence which converges in \( L^q_w(\Omega) \) for \( 1 \leq q < p\sigma \), and the limit of the subsequence belongs to \( L^p_w(\Omega) \).

See the Appendix for analogues of Theorem 3.14 and Corollary 3.15 without the assumption \( w << \nu \).

### 3.4 Local Compactness Results for Degenerate Spaces

In this section, for general bounded measurable sets \( \Omega' \) with \( \overline{\Omega'} \subset \Omega \), we study compact embedding of subsets of \( W^{1,p}_{\nu,\mu}(\Omega, Q) \) into \( L^q_w(\Omega') \) without assuming a global Sobolev estimate for \( \Omega \) or \( \Omega' \) and without assuming \( w(\Omega) < \infty \). For some applications, see the comment at the end of the section.

The theorems below will assume a much weaker condition than the global Sobolev estimate (3.27), namely the following local estimate.
Definition 3.16. Let $1 \leq p < \infty$. We say that the local Sobolev property of order $p$ holds if for some fixed constant $\sigma > 1$ and every compact set $K \subset \Omega$, there is a constant $r_1 > 0$ so that for all $d$-balls $B = B_r(y)$ with $y \in K$ and $0 < r < r_1$,

$$\|f\|_{L_w^p(B)} \leq C(B) \|(f, \nabla f)\|_{W_1^p(\Omega, Q)}$$

if $f \in \text{Lip}_0(B)$, \hspace{1cm} (3.31)

where $C(B)$ is a positive constant independent of $f$. We will view any $f \in \text{Lip}_0(B)$ as extended by 0 to all of $\Omega$.

Remark 3.17. (i) A more standard assumption than (3.31) is a normalized inequality that includes a factor $r$ in the gradient term on the right side:

$$\left( \frac{1}{w(B_r(y))} \int_{B_r(y)} |f|^p \, dw \right)^{\frac{1}{p}} \leq C \left( \frac{1}{\nu(B_r(y))} \int_{B_r(y)} |f|^p \, d\nu \right)^{\frac{1}{p}}$$

$$+ Cr \left( \frac{1}{\mu(B_r(y))} \int_{B_r(y)} |\sqrt{Q} \nabla f|^p \, d\mu \right)^{\frac{1}{p}},$$

with $C$ independent of $r, y$; see e.g. [SW1] and [R1] in the unweighted case with $p = 2$. Clearly (3.32) is a stronger requirement than (3.31).

(ii) In the classical $n$-dimensional elliptic case for linear second order equations in divergence form, $Q$ satisfies $c|\xi|^2 \leq Q(x, \xi) \leq C|\xi|^2$ for some fixed constants $c, C > 0$ and $d$ is the standard Euclidean metric $d(x, y) = |x - y|$. For $1 \leq p < n$ and $\sigma = n/(n - p)$, (3.31) then holds with $dw = d\nu = d\mu = dx$ since the corresponding version of (3.32) is true with $|\sqrt{Q} \nabla f|$ replaced by $|\nabla f|$.

We will also use a notion of Lipschitz cutoff functions on $d$-balls:

Definition 3.18. For $s \geq 1$, we say that the cutoff property of order $s$ holds for $\mu$ if for each compact $K \subset \Omega$, there exists $\delta = \delta(K) > 0$ so that for every $d$-ball $B_r(y)$ with $y \in K$ and $0 < r < \delta$, there is a function $\phi \in \text{Lip}_0(\Omega)$ and a constant $\gamma = \gamma(y, r) \in (0, r)$ satisfying

(i) $0 \leq \phi \leq 1$ in $\Omega$,

(ii) $\text{supp} \, \phi \subset B_r(y)$ and $\phi = 1$ in $B_\gamma(y)$,

(iii) $\nabla \phi \in \mathcal{L}_p^s(\Omega, Q)$.

Since $\mu$ is always assumed to be locally finite, the strongest form of Definition 3.18, namely the version with $s = \infty$, automatically holds if $Q$ is locally bounded in $\Omega$ and (3.12) is true; recall that we always assume (3.2). To see why, fix a compact set $K \subset \Omega$ and consider $B_r(y)$ with $y \in K$ and $r < 1$. Use (3.2) to choose
open Euclidean balls $D', D$ with common center $y$ such that $\overline{D'} \subset D \subset B_r(y) (\subset \Omega$ by definition). Construct a smooth function $\phi$ in $\Omega$ with support in $D$ such that $0 \leq \phi \leq 1$ and $\phi = 1$ on $D'$. By (3.12), there is $\gamma > 0$ such that $B_r(y) \subset D'$. Then $\phi$ satisfies parts (i)-(iii) of Definition 3.18 with $s = \infty$; for (iii), we use the fact that $\nabla \phi$ has compact support in $\Omega$ together with local boundedness of $Q$ and local finiteness of $\mu$.

To compensate for the lack of a global Sobolev estimate, given $\mathcal{H} \subset \text{Lip}_{Q,p}(\Omega)$, we will assume in conjunction with the cutoff property of some order $s \geq p\sigma'$ that for every compact set $K \subset \Omega$, there exists $\delta = \delta(K) > 0$ such that for every $d$-ball $B$ with center in $K$ and radius less than $\delta$, there is a constant $C_1(B)$ so that

$$||f||_{L_p^w(B)} \leq C_1(B)||f, \nabla f||_{W_1^{p,w}(\Omega,Q)}$$

if $f \in \mathcal{H}$, (3.33)

where $t = s/p$ and $1/t + 1/t' = 1$. Note that $1 \leq t' \leq \sigma$ since $s \geq p\sigma'$.

**Remark 3.19.** Inequality (3.33) is different in nature from (3.31) even if $t' = \sigma$ and $w = \mu$ since there is a restriction on supports in (3.31) but not in (3.33). However, (3.33) implies (3.31) when $s = p\sigma'$, $w = \mu$ and $\mathcal{H}$ contains all Lipschitz functions with support in any ball. On the other hand, (3.33) is often automatic if $\mu = \nu$. For example, as mentioned earlier, if $Q$ is locally bounded and (3.12) is true, then the cutoff property holds with $s = \infty$, giving $t = \infty$ and $t' = 1$. In this case, when $\mu = \nu$, the left side of (3.33) is clearly smaller than the right side (in fact smaller than $||f||_{L_p^w(\Omega)}$).

We can now state our main local result.

**Theorem 3.20.** Let the assumptions of §3.1 and condition (3.12) hold, and let $w << \nu$. Fix $p \in [1, \infty)$ and suppose the Poincaré property of order $p$ in Definition 3.5 holds for a fixed set $\mathcal{H} \subset \text{Lip}_{Q,p}(\Omega)$ and the local Sobolev property of order $p$ in Definition 3.16 holds. Assume the cutoff property of some order $s \geq p\sigma'$ is true for $\mu$, with $\sigma$ as in (3.31), and that (3.33) holds for $\mathcal{H}$ with $t = s/p$. Then for every $\{(f_k, g_k)\} \subset \overline{\mathcal{H}}$ that is bounded in $W_1^{1,p}(\Omega,Q)$ norm, there is a subsequence $\{f_{k_i}\}$ of $\{f_k\}$ and an $f \in L_1^w, loc(\Omega)$ such that $f_{k_i} \to f$ pointwise a.e.-$w$ in $\Omega$ and in $L_0^q(\Omega')$ norm for all $1 \leq q < p\sigma$ and every bounded measurable $\Omega'$ with $\overline{\Omega'} \subset \Omega$.

See the Appendix for a version of Theorem 3.20 without assuming $w << \nu$.

Recall that $\overline{\mathcal{H}} = W_{1,p}^1(\Omega,Q)$ if $\mathcal{H} = \text{Lip}_{Q,p}(\Omega)$. In the important case when $Q \in L_{loc}^\infty(\Omega)$, Theorem 3.20 and Remark 3.19 immediately imply the next result.
Corollary 3.21. Let $Q$ be locally bounded in $\Omega$ and suppose that (3.12) holds. Fix $p \in [1, \infty)$, and with $w = \nu = \mu$, assume the Poincaré property of order $p$ holds for $\text{Lip}_Q(\mu)$ and the local Sobolev property of order $p$ holds. Then for every bounded sequence $\{(f_k, \tilde{g}_k)\} \subset W^{1,p}_{w,\text{loc}}(\Omega, Q)$, there is a subsequence $\{f_{k_i}\}$ of $\{f_k\}$ and a function $f \in L^p_{w,\text{loc}}(\Omega)$ such that $f_{k_i} \to f$ pointwise a.e.-$w$ in $\Omega$ and in $L^q_{\mu}(\Omega')$ norm, $1 \leq q < p\sigma$, for every bounded measurable $\Omega'$ with $\overline{\Omega'} \subset \Omega$.

Proof of Theorem 3.20: We begin by using the cutoff property in Definition 3.18 to construct a partition of unity relative to $d$-balls and compact subsets of $\Omega$.

Lemma 3.22. Fix $\Omega$ and $s \geq 1$, and suppose the cutoff property of order $s$ holds for $\mu$. If $K$ is a compact subset of $\Omega$ and $r > 0$, there is a finite collection of \(d\)-balls $\{B_r(y_j)\}$ with $y_j \in K$ together with Lipschitz functions $\{\psi_j\}$ on $\Omega$ such that

(a) $K \subset \bigcup_j B_r(y_j)$,

(b) $0 \leq \psi_j \leq 1$ in $\Omega$ for each $j$, and $\sum_j \psi_j(x) = 1$ for all $x \in K$,

(c) $\nabla \psi_j \in L^s_{\mu}(\Omega, Q)$ for each $j$.

Proof: The argument is an adaptation of one in [Ru] for the usual Euclidean case. The authors thank D. D. Monticelli for related discussions. Fix $r > 0$ and a compact set $K \subset \Omega$, and set $\beta = \min\{\delta/2, r\}$ for $\delta = \delta(K)$ as in Definition 3.18. Since $\beta < \delta$, Definition 3.18 implies that for each $y \in K$, there exist $\gamma(y) \in (0, \beta)$ and $\phi_y(x) \in \text{Lip}(\Omega)$ so that $0 \leq \phi_y \leq 1$ in $\Omega$, $\text{supp} \phi_y \subset B_\beta(y)$, $\phi_y = 1$ in $B_\gamma(y)$ and $\nabla \phi_y \in L^s_{\mu}(\Omega, Q)$. The collection $\{B_{\gamma(y)}\}_{y \in K}$ covers $K$, so by (3.2) and the compactness of $K$, there is a finite subcollection $\{B_{\gamma(y_j)}\}_{j=1}^m$ whose union covers $K$. Part (a) follows since $\gamma(y_j) < r$. Next let $\phi_j(x) = \phi_{y_j}(x)$ and define $\{\psi_j\}_{j=1}^m$ as follows: set $\psi_1 = \phi_1$ and $\psi_j = (1 - \phi_1) \cdots (1 - \phi_{j-1}) \phi_j$ for $j = 2, \ldots, m$. Then each $\psi_j$ is a Lipschitz function in $\Omega$, and $\text{supp} \phi_j \subset B_r(y_j)$ since $\beta < r$. Also, $0 \leq \psi_j \leq 1$ in $\Omega$ and

$$\sum_{j=1}^m \psi_j(x) = 1 - \prod_{j=1}^m (1 - \phi_j(x)), \quad x \in \Omega.$$ 

If $x \in K$ then $x \in B_{\gamma(y_j)}(y_j)$ for some $j$. Hence some $\phi_j(x) = 1$ and consequently $\sum_j \psi_j(x) = 1$. This proves part (b). Lastly, we use Leibniz’s product rule to compute $\nabla \psi_j$ and then apply Minkowski’s inequality $j$ times to obtain part (c)
from the fact that \( \nabla \phi_j \in L^p_\mu(\Omega, Q) \). \( \square \)

The next lemma shows how the local Sobolev estimate (3.31) and Lemma 3.22 lead to a local analogue of the global Sobolev estimate (3.27).

**Lemma 3.23.** Let \( \Omega' \) be a bounded measurable set with \( \overline{\Omega'} \subset \Omega \). Suppose that both Definition 3.16 and the cutoff property for \( \mu \) of some order \( s \geq p \sigma' \) hold, and also that (3.33) holds with \( t = s/p \) for a fixed set \( \mathcal{H} \subset \text{Lip}_{1}(\Omega) \). Then there is a finite constant \( C(\Omega') \) such that

\[
\|f\|_{L^p_\omega(\Omega')} \leq C(\Omega') \|(f, \nabla f)\|_{W^{1,p}_{\psi}(\Omega, Q)} \quad \text{if } f \in \mathcal{H}.
\]

**(Proof):** Let \( r_1 \) be as in Definition 3.16 relative to the compact set \( \overline{\Omega'} \subset \Omega \), and let \( \delta \) be as in (3.33). Use Lemma 3.22 to cover \( \overline{\Omega'} \) by the union of a finite number of \( \mathcal{B} \) balls \( \{B_j\} \) each of radius smaller than \( \min\{r_1, \delta\} \). Associated with this cover is a collection \( \{\psi_j\} \subset \text{Lip}(\Omega) \) with \( \text{supp} \psi_j \subset B_j \), \( \sum_j \psi_j = 1 \) in \( \Omega' \), and \( \nabla \psi_j \in L^\infty_\mu(\Omega, Q) \). If \( f \in \mathcal{H} \), then

\[
\|f\|_{L^p_\omega(\Omega')} = \|f \sum_j \psi_j\|_{L^p_\omega(\Omega')} \leq \sum_j \|\psi_j f\|_{L^p_\omega(B_j)}.
\]

Since \( \psi_j f \in \text{Lip}_0(B_j) \), (3.31) and the product rule give

\[
\|\psi_j f\|_{L^p_\omega(B_j)} \leq C(B_j) \|(\psi_j f, \nabla (\psi_j f))\|_{W^{1,p}_{\psi}(B_j, Q)} = C(B_j) \left( \|\psi_j f\|_{L^p_\omega(B_j)} + \|\sqrt{Q} \nabla (\psi_j f)\|_{L^p_\mu(B_j)} \right) \leq C(B_j) \left( \|\psi_j f\|_{L^p_\omega(B_j)} + \|\sqrt{Q} \nabla f\|_{L^p_\mu(B_j)} + \|f \sqrt{Q} \nabla \psi_j\|_{L^p_\mu(B_j)} \right) \leq C(B_j) \left( \|(f, \nabla f)\|_{W^{1,p}_{\psi}(\Omega, Q)} + \|f \sqrt{Q} \nabla \psi_j\|_{L^p_\mu(B_j)} \right),
\]

where we have used \( |\psi_j| \leq 1 \). We will estimate the second term on the right of (3.36) by using (3.33). Recall that \( t = s/p \geq \sigma' \) and \( 1/t + 1/t' = 1 \). Let

\[
\overline{C} = \max_j \|\sqrt{Q} \nabla \psi_j\|_{L^p_\mu(B_j)}.
\]

By Hölder’s inequality and (3.33),

\[
\|f \sqrt{Q} \nabla \psi_j\|_{L^p_\mu(B_j)} \leq \|f\|_{L^{p'}_\mu(B_j)} \|\sqrt{Q} \nabla \psi_j\|_{L^p_\omega(B_j)} \leq \overline{C} C_1(B_j) \|(f, \nabla f)\|_{W^{1,p}_{\psi}(\Omega, Q)}.
\]
Combining this with (3.36) gives
\[ ||\psi_j f||_{L^p(w)(B_j)} \leq C(B_j) (1 + C C_1(B_j)) ||(f, \nabla f)||_{W^{1,p}_w(\Omega, Q)} . \]
By (3.35), for any \( f \in \mathcal{H} \),
\[ ||f||_{L^p(w)(\Omega')} \leq ||(f, \nabla f)||_{W^{1,p}_w(\Omega, Q)} \sum_j C(B_j) (1 + C C_1(B_j)) = C(\Omega') ||(f, \nabla f)||_{W^{1,p}_w(\Omega, Q)} , \]
which completes the proof of Lemma 3.23. \( \square \)

Theorem 3.20 follows from Lemma 3.23 and Theorem 1.4. We will sketch the proof, omitting some familiar details. By choosing a sequence of compact sets increasing to \( \Omega \) and using a diagonalization argument, it is enough to prove the conclusion for a fixed measurable \( \Omega' \) with compact closure \( \overline{\Omega'} \) in \( \Omega \). Fix such a \( \Omega' \) and select a bounded open \( \Omega'' \) with \( \overline{\Omega'} \subset \Omega'' \subset \overline{\Omega'} \subset \Omega \). For \( \mathcal{H} \) as in Theorem 3.20, apply Lemma 3.23 to the set \( \Omega'' \) to obtain
\[ ||f||_{L^p_w(\Omega'')} \leq C(\Omega'') ||(f, \nabla f)||_{W^{1,p}_w(\Omega, Q)} , \quad f \in \mathcal{H} . \] (3.38)
By assumption, \( w << \nu \), so (3.38) extends to \( \overline{\mathcal{H}} \) in the form
\[ ||f||_{L^p_w(\Omega'')} \leq C(\Omega'') ||(f, \tilde{g})||_{W^{1,p}_w(\Omega, Q)} , \quad (f, \tilde{g}) \in \overline{\mathcal{H}} . \] (3.39)

Let \( \epsilon > 0 \). By hypothesis, \( \mathcal{H} \) satisfies the Poincaré estimate (3.8) for balls \( B_r(y) \) with \( y \in \overline{\Omega'} \) and \( r < \delta(\epsilon, \Omega') \). Since the Euclidean distance between \( \overline{\Omega'} \) and \( \partial \Omega'' \) is positive and we have assumed (3.12), we may also assume by Remark 3.6(ii) that all such balls lie in the larger set \( \Omega'' \). Next we claim that (3.8) extends to \( \overline{\mathcal{H}} \), i.e.,
\[ \left( \int_{B_r(y)} |f - f_{B_r(y), w}|^p dw \right)^{\frac{1}{p}} \leq \epsilon ||(f, \tilde{g})||_{W^{1,p}_w(B_{\delta r(y)}, Q)} \quad \text{if } (f, \tilde{g}) \in \overline{\mathcal{H}} , \] (3.40)
for the same class of balls \( B_r(y) \). In fact, if \( (f, \tilde{g}) \in \overline{\mathcal{H}} \) and \( \{f^j\} \subset \mathcal{H} \) satisfies \( (f^j, \nabla f^j) \to (f, \tilde{g}) \) in \( W^{1,p}_w(\Omega, Q) \) norm, then there is a subsequence, still denoted \( \{f^j\} \), with \( f^j \to f \) a.e.-\( \nu \) in \( \Omega \), and so with \( f^j \to f \) a.e.-\( w \) in \( \Omega \) since \( w << \nu \). By (3.38), \( \{f^j\} \) is bounded in \( L^p_w(\Omega'') \). Hence, since the balls in (3.40) satisfy \( B_r(y) \subset \Omega'' \), we obtain \( f^j_{B_r(y), w} \to f_{B_r(y), w} \) by our usual weak convergence argument, and (3.40) follows by Fatou’s lemma from its analogue (3.8) for the \( (f^j, \nabla f^j) \).
Now let $\{(f_k, \tilde{g}_k)\} \subset \overline{\mathcal{H}}$ be bounded in $W^{1,p}_{\nu,\mu}(\Omega, Q)$ norm and apply Theorem 1.4 with $\mathcal{X}(\Omega) = L^p_\mu(\Omega) \times L^p_\mu(\Omega, Q)$ to the set $\mathcal{S}$ defined by

$$\mathcal{S} = \{(f_k, (f_k, \tilde{g}_k))\}_k,$$

and with $\{(E'_\ell, F'_\ell)\}_\ell$ chosen to be a finite number of pairs $\{(B_r(y_t), B_{c_r}(y_t))\}_\ell$ as in (3.40), but now with $r$ fixed depending on $\epsilon$, and with $\Omega' \subset \bigcup \overline{B_r(y_t)}$. Such a finite choice exists by (3.2) and the Heine-Borel theorem since $\overline{\Omega'}$ is compact; cf. the proof of Lemma 3.12. Since $\Omega'$ is completely covered by $\bigcup \overline{E'_\ell}$, assumption (i) of Theorem 1.4 is fulfilled. Moreover, the collection $\{F'_\ell\}$ has bounded overlaps uniformly in $\epsilon$ by the geometric doubling argument used to prove Lemma 3.12.

Finally, (1.15) follows from (3.39) applied to the bounded sequence $\{(f_k, \tilde{g}_k)\}$ since $\bigcup \overline{E'_\ell} \subset \Omega''$. Thus Theorem 1.4 implies that there is a subsequence $\{f_{k_i}\}$ of $\{f_k\}$ and a function $f \in L^p_w(\Omega')$ such that $f_{k_i} \to f$ a.e.-w in $\Omega'$ and in $L^q_w(\Omega')$ norm, $1 \le q < p\sigma$. This completes the proof of Theorem 3.20.

For functions which are compactly supported in a fixed bounded measurable $\Omega'$ with $\overline{\Omega'} \subset \Omega$, the proof of Theorem 3.20 can be modified to yield compact embedding into $L^q_w(\Omega')$ for the same $\Omega'$ without assuming (3.12). Of course we always require (3.2). Given such $\Omega'$ and a set $\mathcal{H} \subset \text{Lip}_{Q,p,0}(\Omega')$, we may view $\mathcal{H}$ as a subset of $\text{Lip}_{Q,p,0}(\Omega)$ simply by extending functions in $\mathcal{H}$ to all of $\Omega$ as $0$ in $\Omega \setminus \Omega'$. In this way, the proof of Theorem 3.20 works without (3.12). For example, choosing $\mathcal{H} = \text{Lip}_{Q,p,0}(\Omega')$, we obtain

**Theorem 3.24.** Let the assumptions of §3.1 hold and $w << \nu$. Let $\Omega'$ be a bounded measurable set with $\overline{\Omega'} \subset \Omega$. Fix $p \in [1, \infty)$ and suppose the Poincaré property of order $p$ in Definition 3.5 holds for $\text{Lip}_{Q,p,0}(\Omega')$, with $\text{Lip}_{Q,p,0}(\Omega')$ viewed as a subset of $\text{Lip}_{Q,p,0}(\Omega)$ using extension by 0, and suppose the local Sobolev property of order $p$ in Definition 3.16 holds. Assume the cutoff property of some order $s \ge p\sigma'$ is true for $\mu$, with $\sigma$ as in (3.31), and that (3.33) holds for $\text{Lip}_{Q,p,0}(\Omega')$ with $t = s/p$. Then for every sequence $\{(f_k, \tilde{g}_k)\} \subset W^{1,p}_{\nu,\mu,0}(\Omega', Q)$ which is bounded in $W^{1,p}_{\nu,\mu,0}(\Omega', Q)$ norm, there is a subsequence $\{f_{k_i}\}$ of $\{f_k\}$ and a function $f \in L^p_w(\Omega')$ such that $f_{k_i} \to f$ pointwise a.e.-w in $\Omega'$ and in $L^q_w(\Omega')$ norm, $1 \le q < p\sigma$.

The full force of the local Sobolev estimate in Definition 3.16 is not needed to prove Theorem 3.24. In fact, it is enough to assume that (3.31) holds only for balls centered in the fixed compact set $\overline{\Omega'}$.

The proof of Theorem 3.24 is like that of Theorem 3.20, working with the set $\Omega'$ that occurs in the hypotheses of Theorem 3.24. However, now (3.34) in the conclusion of Lemma 3.23 (with $\mathcal{H} = \text{Lip}_{Q,p,0}(\Omega')$) remains valid if $\Omega'$ is replaced.
on the left side by \( \Omega \) since every \( f \in \text{Lip}_{Q,p,0}(\Omega') \) vanishes on \( \Omega \setminus \Omega' \). The resulting estimate serves as a replacement for (3.38), so it is not necessary to demand that the \( E^\epsilon \ell \) are subsets of a compact set \( \overline{\Omega'} \subset \Omega \). Hence (3.12) is no longer required. Finally, the Poincaré estimate extends as usual to \( W^{1,p}_\nu,\mu,0(\Omega',Q) \) (the closure of \( \text{Lip}_{Q,p,0}(\Omega') \)), and due to support considerations, the \( E^\epsilon \ell \) can be restricted to subsets of \( \Omega' \) by replacing \( E^\epsilon \ell \) by \( E^\epsilon \ell \cap \Omega' \); this guarantees \( w(E^\epsilon \ell) < \infty \) since \( w \) is locally finite by hypothesis.

Recalling the comments made immediately after Definition 3.18 and in Remark 3.19, we obtain a useful special case of Theorem 3.24:

**Corollary 3.25.** Let the assumptions of §3.1 hold, \( \Omega \) and \( Q \) be bounded, \( w = \nu = \mu \) and (3.12) be true. Let \( \Omega' \) be a measurable set with \( \overline{\Omega'} \subset \Omega \). Fix \( p \in [1, \infty) \) and suppose the Poincaré property of order \( p \) in Definition 3.5 holds for \( \text{Lip}_{Q,p,0}(\Omega') \) and the local Sobolev property of order \( p \) in Definition 3.16 holds. Then for every \( \{(f_k, g_k)\} \subset W^{1,p}_\nu,\mu,0(\Omega',Q) \) which is bounded in \( W^{1,p}_\nu,\mu(\Omega',Q) \) norm, there is a subsequence \( \{f_k\} \) of \( \{f_k\} \) and a function \( f \in L^p(\Omega') \) such that \( f_k \rightarrow f \) pointwise a.e.-w in \( \Omega' \) and in \( L^q(\Omega') \) norm, \( 1 \leq q < p\sigma \).

In case \( p = 2 \) and all measures are Lebesgue measure, Corollary 3.25 is used in [R1] to show existence of weak solutions to Dirichlet problems for some linear subelliptic equations. It is also used in [R2] to derive the global Sobolev inequality

\[
\|f\|_{L^2(\Omega')} \leq C \left( \int_{\Omega'} |\sqrt{Q} \nabla f|^2 \, dx \right)^{1/2}
\]

(3.41)

for open \( \Omega' \) with \( \overline{\Omega'} \subset \Omega \) from the local estimate (3.32).

### 4 Precompact subsets of \( L^N \) in a quasimetric space

In this section, we will consider the situation of an open set \( \Omega \) in a topological space \( X \) when \( X \) is also endowed with a quasimetric \( d \). As there is no easy way to define Sobolev spaces on general quasimetric spaces, this section concentrates on establishing a simple criterion not directly related to Sobolev spaces ensuring that bounded subsets of \( L^N_w(\Omega) \) are precompact in \( L^q_w(\Omega) \) when \( 1 \leq q < N \leq \infty \).

We begin by further describing the setting for our result. The topology on \( X \) is expressed in terms of a fixed collection \( T \) of subsets of \( X \) which may not be related to the quasimetric \( d \). Thus when we say that a set \( \mathcal{O} \subset X \) is open, we mean that

\[
\|f\|_{L^2(\Omega')} \leq C \left( \int_{\Omega'} |\sqrt{Q} \nabla f|^2 \, dx \right)^{1/2}
\]
\( \mathcal{O} \in \mathcal{T} \). Given an open \( \Omega \), we will assume each of the following:

(i) \( \forall x \in X \) and \( r > 0 \), the \( d \)-ball \( B_r(x) = \{ y \in X : d(x, y) < r \} \) is a Borel set;

(ii) \( \forall x \in X \) and \( r > 0 \), there is an open set \( \mathcal{O} \) so that \( x \in \mathcal{O} \subset B_r(x) \);

(iii) if \( X \neq \Omega \), then \( \forall x \in \Omega \), \( d(x, \Omega^c) = \inf \{ d(x, y) : y \in \Omega^c \} > 0 \).

Property (ii) serves as a substitute for (3.2).

Unlike the situation in §3, \( d \)-balls centered in \( \Omega \) may not be subsets of \( \Omega \) unless \( X = \Omega \). However, we note the following fact.

**Remark 4.1.** Properties (ii) and (iii) guarantee that for any compact set \( K \subset \Omega \), there exists \( \varepsilon(K) > 0 \) such that \( B_r(x) \subset \Omega \) if \( x \in K \) and \( r < \varepsilon(K) \). In fact, first note that for any \( x \in \Omega \), (iii) implies that the \( d \)-ball \( B(x) \) with center \( x \) and radius \( r = d(x, \Omega^c)/(2\kappa) \) lies in \( \Omega \). If \( K \) is a compact set in \( \Omega \), (ii) shows that \( K \) can be covered by a finite number of such balls \( \{ B(x_i) \} \). With \( \varepsilon(K) \) chosen to be a suitably small multiple (depending on \( \kappa \)) of \( \min \{ r_{x_i} \} \), the remark then follows easily from the swallowing property of \( d \)-balls.

Further, we assume that \( (\Omega, d) \) satisfies the local geometric doubling condition in Definition 3.3, i.e., for each compact set \( K \subset \Omega \), there exists \( \delta'(K) > 0 \) such that for all \( x \in K \) and all \( 0 < r' < r < \delta'(K) \), the number of disjoint \( d \)-balls of common radius \( r' \) contained in \( B_r(x) \) is at most a constant \( C_{r/r'} \) depending on \( r/r' \) but not on \( K \). We will choose \( \delta'(K) \leq \varepsilon(K) \) in the above.

With this framework in force, we now state the main result of the section.

**Theorem 4.2.** Let \( \Omega \subset X \) be as above, and let \( w \) be a finite Borel measure on \( \Omega \) such that given any \( \varepsilon > 0 \), there is a compact set \( K \subset \Omega \) with \( w(\Omega \setminus K) < \varepsilon \). Let \( 1 \leq p < \infty \) and \( 1 < N \leq \infty \), and suppose \( S \subset L_w^N(\Omega) \) has the property that for any compact set \( K \subset \Omega \), there exists \( \delta_K > 0 \) such that

\[
\| f - f_{B,x} \|_{L_w^p(B)} \leq b(f, B) \quad \text{if } f \in S \text{ and } B = B_r(x), \ x \in K, \ 0 < r < \delta_K, \quad (4.1)
\]

where \( b(f, B) \) is a nonnegative ball set function. Further, suppose there is a constant \( c_0 \geq 1 \) so that for every \( \varepsilon > 0 \) and every compact set \( K \subset \Omega \), there exists \( \delta_{\varepsilon,K} > 0 \) such that

\[
\sum_{B \in \mathcal{F}} b(f, B)^p \leq c^p \quad \text{for all } f \in S \quad (4.2)
\]

for every finite family \( \mathcal{F} = \{ B \} \) of \( d \)-balls centered in \( K \) with common radius less than \( \delta_{\varepsilon,K} \) for which \( \{ c_0 B \} \) is a pairwise disjoint family of subsets of \( \Omega \). Then any sequence in \( S \) that is bounded in \( L_w^N(\Omega) \) has a subsequence that converges in \( L_w^q(\Omega) \) for \( 1 \leq q < N \) to a function in \( L_w^N(\Omega) \).
Proof. Let $\epsilon > 0$ and choose a compact set $K \subset \Omega$ with $w(\Omega \setminus K) < \epsilon$. Next, for $c_0 \geq 1$, as in the proof of Lemma 3.12 there is a positive constant $r = r(\epsilon, K, c_0) < \min\{\delta_K, \delta(K), \varepsilon(K)/(\gamma c_0)\}$ (see (4.1),(4.2), Definition 3.3 and Remark 4.1), where $\gamma = \kappa + 2\kappa^2$ with $\kappa$ as in (3.1), and a finite family $\{B_r(y_k)\}_k$ of $d$-balls centered in $K$ satisfying $K \subset \bigcup_k B_r(y_k)$ and whose dilates $\{B_{c_0r}(y_k)\}_k$ lie in $\Omega$ and have the bounded intercept property (with intercept constant $M$ independent of $\epsilon$). Since $\{B_{c_0r}(y_k)\}_k$ has bounded intercepts with bound $M$, it can be written as the union of at most $M$ families of disjoint $d$-balls; see e.g. the proof of [CW1, Lemma 2.5]. By (4.2), we conclude that

$$\sum_k b(f, B_{c_0r}(y_k))^p \leq M\epsilon^p.$$ 

Theorem 4.2 then follows immediately from Theorem 1.2; see also Remark 1.3(1).

As an application of Theorem 4.2 we present a version of [HK2, Theorem 8.1] in the case $p \geq 1$. Our version improves the one in [HK2] by allowing two different measures and by relaxing the assumptions made about embedding and doubling. Furthermore, while the analogue in [HK2] of our (4.3) uses only the $L^1_w(B)$ norm on the left side, it automatically self-improves to the $L^p_w(B)$ norm due to the doubling assumption, with a further fixed enlargement of the ball $c_0B$ on the right side; see e.g. [HK2, Theorem 5.1].

Corollary 4.3. Let $X, d, \Omega, w$ be as above, and let $\mu$ be a Borel measure on $\Omega$. Fix $1 \leq p < \infty$, $1 < N \leq \infty$ and $c_0 \geq 1$. Consider a sequence of pairs $\{(f_i, g_i)\} \subset L^N_w(\Omega) \times L^p_\mu(\Omega)$ such that for any compact set $K \subset \Omega$, there exists $\tilde{\delta}_K > 0$ with

$$||f_i - (f_i)_{B_{c_0B}}||_{L^p_w(B)} \leq a_+(B)||g_i||_{L^p_\mu(c_0B)}$$  \quad (4.3)

for all $i$ and all $d$-balls $B$ centered in $K$ with $c_0B \subset \Omega$ and $r(B) < \tilde{\delta}_K$, where $a_+(B)$ is a non-negative ball set function satisfying

$$\lim_{r \to 0} \left\{ \sup_{y \in K} a_+(B_r(y)) \right\} = 0.$$  \quad (4.4)

Then if $\{f_i\}$ and $\{g_i\}$ are bounded in $L^N_w(\Omega)$ and $L^p_\mu(\Omega)$ respectively, $\{f_i\}$ has a subsequence converging in $L^q_w(\Omega)$ for $1 \leq q < N$ to a function belonging to $L^N_w(\Omega)$.

Proof. Given $\epsilon > 0$ and compact set $K \subset \Omega$, use (4.4) to choose $r_0 > 0$ so that $a_+(B_r) < \epsilon/\beta$ for any $d$-ball $B_r$ centered in $K$ with $r < r_0$, where $\beta =$
sup_i \|g_i\|_{L^p_\mu(\Omega)} < \infty. In Theorem 4.2, choose \( S = \{f_i\} \), \( \delta_K = \tilde{\delta}_K \), \( b(f_i, B) = a_*(B)\|g_i\|_{L^p_\mu(c_0 B)} \) and

\[
\tilde{\delta}_{\epsilon,K} = \min\{\delta_K, \delta'(K), r_0, \epsilon(K)/c_0\}.
\]

If \( B \) is a \( d \)-ball with center in \( K \) and \( r(B) < \tilde{\delta}_{\epsilon,K} \), then \( c_0 B \subset \Omega \). Hence,

\[
\sum_{B \in \mathcal{F}} (a_*(B)\|g_i\|_{L^p_\mu(c_0 B)})^p \leq \epsilon^p \|g_i\|_{L^p_\mu(\Omega)}^p / \beta^p \leq \epsilon^p
\]

for every \( \mathcal{F} \) as in Theorem 4.2. The conclusion now follows from Theorem 4.2. \( \square \)

**Remark 4.4.**

1. The \( g_i \) in (4.3) are usually the modulus of a fixed derivative of the corresponding \( f_i \), such as \(|\nabla f_i|\) when \( X \) is a Riemannian manifold. More generally, \( g_i \) may be the upper gradient of \( f_i \) (see [Hei] for the definition).

2. Theorem 4.2 can also be used to obtain an extension of Theorem 2.3 to \( s \)-John domains in quasimetric spaces; see [CW2, Theorem 1.6].

## 5 Appendix

Here we briefly consider analogues of Theorem 3.14, Corollary 3.15 and Theorem 3.20 without assuming \( w << \nu \), but adding the assumption that \( \mathcal{H} \) is linear. In this case, (3.27) can be extended by continuity to obtain a bounded linear map from \( \overline{\mathcal{H}} \) into \( L^p_w(\Omega) \). Here, as always, \( \overline{\mathcal{H}} \) denotes the closure of \( \{(f, \nabla f) : f \in \mathcal{H}\} \) in \( W^{1,p}_{\nu,\mu}(\Omega, Q) \). However, when \( w << \nu \) fails, there is no natural way to obtain the extension for every \((f, \bar{g}) \in \overline{\mathcal{H}}\) keeping the same \( f \) on the left side. In fact, let \((f, \bar{g}) \in \overline{\mathcal{H}}\) and choose \( \{f_j\} \subset \mathcal{H} \) with \((f_j, \nabla f_j) \to (f, \bar{g}) \) in \( W^{1,p}_{\nu,\mu}(\Omega, Q) \). Linearity of \( \mathcal{H} \) allows us to apply (3.27) to differences of the \( f_j \) and conclude that \( \{f_j\} \) is a Cauchy sequence in \( L^p_w(\Omega) \). Therefore \( f_j \to f^* \) in \( L^p_w(\Omega) \) for some \( f^* \in L^p_w(\Omega) \), and

\[
\|f^*\|_{L^p_w(\Omega)} \leq C\|(f, \bar{g})\|_{W^{1,p}_{\nu,\mu}(\Omega, Q)} \quad \text{if} \quad (f, \bar{g}) \in \overline{\mathcal{H}}.
\]

The function \( f^* \) is determined by \((f, \bar{g})\), i.e., \( f^* \) is independent of the particular sequence \( \{f_j\} \subset \mathcal{H} \) above. Indeed, if \( \{\tilde{f}_j\} \) is another sequence in \( \mathcal{H} \) with \((\tilde{f}_j, \nabla \tilde{f}_j) \to (f, \bar{g}) \) in \( W^{1,p}_{\nu,\mu}(\Omega, Q) \), and if \( \tilde{f}_j \to \tilde{f}^* \) in \( L^p_w(\Omega) \), then by (3.27) and linearity of \( \mathcal{H} \),

\[
\|\tilde{f}_j - f_j\|_{L^p_w(\Omega)} \leq C\|((\tilde{f}_j - f_j, \nabla \tilde{f}_j - \nabla f_j))\|_{W^{1,p}_{\nu,\mu}(\Omega, Q)} \to 0.
\]
Consequently $||f^* - f^*||_{L^p_w(\Omega)} = 0$. Thus $(f, \bar{g})$ determines $f^*$ uniquely as an element of $L^p_w(\Omega)$. Define a mapping

$$T : \mathcal{H} \to L^p_w(\Omega) \quad \text{by setting } T(f, \bar{g}) = f^*.$$  

(5.1)

Note that $\mathcal{H}$ is a linear set in $W^{1,p}_{v,\mu}(\Omega, Q)$ since $\mathcal{H}$ is linear, and that $T$ is a bounded linear map from $\mathcal{H}$ into $L^p_w(\Omega)$. Also note that $T$ satisfies $T(f, \nabla f) = f$ when restricted to those $(f, \nabla f)$ with $f \in \mathcal{H}$. Furthermore, if $w << \nu$ then $T(f, \bar{g}) = f$ for all $(f, \bar{g}) \in \mathcal{H}$, i.e., $f^* = f$ a.e.-$w$ for all $(f, \bar{g}) \in \mathcal{H}$. This follows since $f_j \to f$ in $L^p_w(\Omega)$ norm and $f_j \to f^*$ in $L^p_w(\Omega)$ norm. In this appendix, where it is not assumed that $w << \nu$, $f^*$ plays a main role. One can find a function $h$ such that $h = f^*$ a.e.-$w$ and $h = f$ a.e.-$\nu$, but as this fact is not needed, we omit its proof.

An analogue of Theorem 3.14 is given in the next result.

**Theorem 5.1.** Let all the assumptions of Theorem 3.14 hold except that now the set $\mathcal{H}$ is linear and we do not assume $w << \nu$. Then the map $T : \mathcal{H} \to L^p_w(\Omega)$ defined in (5.1) is compact if $1 \le q < p \sigma$. Equivalently, if $\{(f_k, \bar{g}_k)\}$ is a sequence in $\mathcal{H}$ with $\sup_k ||(f_k, \bar{g}_k)||_{W^{1,p}_{v,\mu}(\Omega, Q)} < \infty$, then $\{f_k^*\}$ has a subsequence which converges in $L^p_w(\Omega)$ for $1 \le q < p \sigma$, where $f_k^* = T(f_k, \bar{g}_k)$. Moreover, the limit of the subsequence belongs to $L^p_w(\Omega)$.

**Proof:** Let $\mathcal{H}$ satisfy the hypothesis of the theorem and let $\{(f_k, \bar{g}_k)\} \subset \mathcal{H}$ be bounded in $W^{1,p}_{v,\mu}(\Omega, Q)$. For each $k$, choose $h_k \in \mathcal{H}$ so that

$$||(f_k, \bar{g}_k) - (h_k, \nabla h_k)||_{W^{1,p}_{v,\mu}(\Omega, Q)} \le 2^{-k}.$$  

(5.2)

Set $\mathcal{H}_1 = \{h_k\}_k \subset \mathcal{H}$. Then $\{(h_k, \nabla h_k) : h_k \in \mathcal{H}_1\}$ is bounded in $W^{1,p}_{v,\mu}(\Omega, Q)$. Further, (3.27) implies a version of (3.14), namely

$$\sup_{f \in \mathcal{H}_1} \left\{ ||f||_{L^p_w(\Omega)} + ||(f, \nabla f)||_{W^{1,p}_{v,\mu}(\Omega, Q)} \right\} < \infty.$$

Theorem 3.7 now applies to $\mathcal{H}_1$ with $N = p \sigma$ and gives that any sequence in $\mathcal{H}_1$ has a subsequence which converges in $L^p_w(\Omega)$ norm for $1 \le q < p \sigma$ to a function belonging to $L^p_w(\Omega)$. The sequence $\{h_k\}$ lies in $\mathcal{H}_1$, as is easily seen by considering, for each fixed $k$, the constant sequence $\{f^j\}$ defined by $f^j = h_k$ for all $j$. We conclude that $\{h_k\}$ has a subsequence $\{h_{k_i}\}$ converging in $L^p_w(\Omega)$ norm for $1 \le q < p \sigma$ to a function $h \in L^p_w(\Omega)$. By linearity and boundedness of $T$ from $\mathcal{H}$ to $L^p_w(\Omega)$ together with (5.2), we have (writing $f^*_k = T(f_k, \bar{g}_k)$)

$$||f^*_k - h_k||_{L^p_w(\Omega)} = ||T(f_k, \bar{g}_k) - T(h_k, \nabla h_k)||_{L^p_w(\Omega)} \le C 2^{-k} \to 0.$$
Restricting \( k \) to \( \{k_i\} \) and using \( w(\Omega) < \infty \), we conclude that \( \{f^*_k\} \) also converges to \( h \) in \( L^q_w(\Omega) \) for \( 1 \leq q < p\sigma \), which completes the proof. \( \square \)

Setting \( \mathcal{H} = \text{Lip}_{Q,p}(\Omega) \) in Theorem 5.1 gives an analogue of Corollary 3.15:

**Corollary 5.2.** Let the hypotheses of Theorem 5.1 hold for \( \mathcal{H} = \text{Lip}_{Q,p}(\Omega) \). Then the map \( T \) defined by (5.1) is a compact map of \( W^{1,p}_{\nu,\mu}(\Omega, Q) \) into \( L^q_w(\Omega) \) for \( 1 \leq q < p\sigma \), i.e., if \( \{(f_k, \vec{g}_k)\} \subset W^{1,p}_{\nu,\mu}(\Omega, Q) \) and \( \sup_k ||(f_k, \vec{g}_k)||_{W^{1,p}_{\nu,\mu}(\Omega, Q)} < \infty \), then \( \{f^*_k\} \) has a subsequence which converges in \( L^q_w(\Omega) \) for \( 1 \leq q < p\sigma \), where \( f^*_k = T(f_k, \vec{g}_k) \). Moreover, the limit of the subsequence belongs to \( L^{p\sigma}_w(\Omega) \).

Theorem 3.20 also has an analogue without assuming \( w << \nu \) provided \( \mathcal{H} \) is linear, and in this instance (3.27) is not required: the subsequence \( \{f_k\} \) of \( \{f_k\} \) in the conclusion is then replaced by a subsequence of \( \{f^*_k\} \), where \( f^*_k \) is constructed as above but now using bounded measurable \( \Omega' \) whose closures increase to \( \Omega \). Now \( f^* \) arises when (3.38) is extended to \( \overline{\mathcal{H}} \), namely, instead of (3.39), we obtain

\[
||f^*||_{L^{p\sigma}_w(\Omega')} \leq C(\Omega'') ||(f, \vec{g})||_{W^{1,p}_{\nu,\mu}(\Omega, Q)} \quad \text{if } (f, \vec{g}) \in \overline{\mathcal{H}}
\]

where \( f^* \) is constructed for a pair \( (f, \vec{g}) \in \overline{\mathcal{H}} \) by using linearity of \( \mathcal{H} \) and (3.38) for a particular \( (\Omega', \Omega'') \). It is easy to see that \( f^* \in L^{p\sigma}_{w,loc}(\Omega) \) by letting \( \Omega' \nearrow \Omega \). The Poincaré inequality analogous to (3.40) is

\[
\left( \int_{B_r(\overline{y})} |f^* - f^*_r(\overline{y}), w|^p dw \right)^{1/p} \leq \epsilon ||(f, \vec{g})||_{W^{1,p}_{\nu,\mu}(B_{r_0}(\overline{y}), Q)} \quad \text{if } (f, \vec{g}) \in \overline{\mathcal{H}},
\]

obtained by extending (3.8) from \( \mathcal{H} \) to \( \overline{\mathcal{H}} \). Further details are omitted.
