RELATION BETWEEN NON-EXCHANGEABILITY AND MEASURES OF CONCORDANCE OF COPULAS

DAMJANA KOKOL BUKOVŠEK, TOMAŽ KOŠIR, BLAŽ MOJŠKERC, AND MATJAŽ OMLADIČ

ABSTRACT. An investigation is presented of how a comprehensive choice of five most important measures of concordance (namely Spearman’s rho, Kendall’s tau, Gini’s gamma, Blomqvist’s beta, and their weaker counterpart Spearman’s footrule) relate to non-exchangeability, i.e., asymmetry on copulas. Besides these results, the method proposed also seems to be new and may serve as a raw model for exploration of the relationship between a specific property of a copula and some of its measures of dependence structure, or perhaps the relationship between various measures of dependence structure themselves.

1. INTRODUCTION

Copulas are mathematical objects that capture the dependence structure among random variables. Since they were introduced by A. Sklar in 1959 [34] they have gained a lot of popularity and applications in several fields, e.g., in finance, insurance and reliability theory. Through them we model the dependence between random variables by building (bivariate) distributions with given marginal distributions. When deciding about which copulas to apply in real life scenarios the practitioners need to compare how certain statistical concepts behave on their data and on a class of copulas they intend to exploit.

An important family of the kind of notions are measures of concordance (cf. [27, 11]) such as Kendall’s tau and Spearman’s rho. Perhaps even more important is the notion of symmetry, also called exchangeability, or the lack of it. These notions have been studied extensively and increasingly. Nevertheless, the main contribution of this paper, i.e., the investigation of the relation between the two, appears to be new. What we do here is study a comprehensive choice of five most important measures of concordance (namely Spearman’s rho, Kendall’s tau, Gini’s gamma, Blomqvist’s beta, and their weaker counterpart Spearman’s footrule) on a narrow class of copulas that are equally nonexchangeable, in other words, they are asymmetric in an equivalent way to be defined later.

Let us present here some notation needed in the paper. We denote by $C$ the set of all bivariate copulas and by $I$ the interval $[0, 1] \subseteq \mathbb{R}$. For a copula $C \in C$ we denote throughout the paper by $C^t$ the transpose of $C$, i.e., $C^t(u, v) = C(v, u)$ for all $(u, v) \in I^2$. We also denote
by $C^{σ_1}$ and $C^{σ_2}$ the two reflections on a copula $C$ defined by $C^{σ_1}(u,v) = v - C(1-u,v)$ and $C^{σ_2}(u,v) = u - C(u,1-v)$ (see [11, §1.7.3]), and by $\hat{C}$ the survival copula of $C$.

Several orders can be introduced on $C$. Copula $C$ is preceding $D$ in the concordance order if $C(u,v) \leq D(u,v)$ and $\hat{C}(u,v) \leq \hat{D}(u,v)$ for all $(u,v) \in I^2$ [22, Definition 2.4]. Copula $C$ is preceding $D$ in the pointwise order if only $C(u,v) \leq D(u,v)$ for all $(u,v) \in I^2$. (See [21, Definition 2.8.1] and [22, §2.11] for further details.) The concordance order and the pointwise order coincide on the set of two-dimensional copulas. (See [21, §2.2.1] for a proof of this statement.) Hence, we will simply refer to them as the order, and write $C \leq D$ for $C, D \in \mathcal{C}$ if $C(u,v) \leq D(u,v)$ for all $(u,v) \in I^2$. It is well known that $\mathcal{C}$ is a partially ordered set with respect to the order, but not a lattice [32, Theorem 2.1], and that $W(u,v) = \max\{0,u + v - 1\}$ and $M(u,v) = \min\{u,v\}$ are the lower and the upper bound of all copulas, respectively. Copulas $W$ and $M$ are called the Fréchet-Hoeffding lower and upper bound, respectively.

Besides these global bounds one often studies local bounds of certain sets of copulas. Perhaps among the first known examples of the kind is given in Theorem 3.2.3 of Nelsen’s book [27] (cf. also [29, Theorem 1]), where the bounds of the set of copulas $C \in \mathcal{C}$ with $C(a,b) = \theta$ for fixed $a,b \in I$ and $\theta \in [W(a,b), M(a,b)]$ are given. In general, if $C_0$ is a set of copulas, we let

\[
C = \inf C_0 \quad \text{and} \quad \overline{C} = \sup C_0.
\]

In [29] the authors study the bounds for the set of copulas whose Kendall’s tau equals a given number $t \in (-1,1)$ and for the set of copulas whose Spearman’s rho equals a given number $t \in (-1,1)$. In both cases the bounds are copulas which do not belong to the set. Similar bounds for the set of copulas having a fixed value of Blomqvist’s beta were found in [31]. In [3] the authors present the local bounds for the set of copulas having a fixed value of the degree of nonexchangeability. Observe that this amounts to the same as studying the set of copulas having a fixed value of Blomqvist’s beta. We determine the local bounds of this set given by (1). For any $c$ of the kind we compute the possible range of a certain measure of concordance on this set. We believe that the so defined set is more appropriate to investigate the relationship between asymmetry and measures of concordance than the set proposed in [3].

We are now in position to explain some of our main results. The authors of [24] introduce in §2 following the ideas of [23] the so-called maximal asymmetry function. This function determines maximal possible asymmetry $d^*(a,b)$ on the set of all copulas $\mathcal{C}$ at a given point $(a,b)$ of the unit square $I^2$. Given a fixed $c \in [0,d^*(a,b)]$ we define $C_c$ as the set of copulas for which the value of the maximal asymmetry function at $(a,b)$ equals $c$. We determine the local bounds of this set given by (1). For any $c$ of the kind we compute the possible range of a certain measure of concordance on this set. We believe that the so defined set is more appropriate to investigate the relationship between asymmetry and measures of concordance than the set proposed in [3].

The paper is organized as follows. Section 2 contains preliminaries on asymmetry leading to Theorem 2 of our main results. Section 3 contains preliminaries on measures of concordance. In Section 4 we present the elaboration of measures of concordance on local bounds described in Theorem 2. This part of the paper is technically quite involved. The relations between the two notions are then studied in Sections 5 to 9 for Spearman’s rho, Kendall’s tau, Spearman’s footrule, Gini’s gamma, and Blomqvist’s beta, respectively. So, among the main
results of the paper we should point out Theorems 9, 12, 15, 18 and 20 and Corollaries 10, 13, 
16, 19 and 21 together with Figures 6 to 11. Some concluding thoughts are given in Section 10.

2. Maximally asymmetric copulas

In this paper we study relations between various measures of concordance and a measure of 
non-exchangeability $\mu$. The topic of non-exchangeability or asymmetry of copulas is attracting 
much attention (see e.g. [4, 8, 9, 10, 15, 19, 23, 24, 28]). To quantify the non-exchangeability 
or asymmetry the authors in [7] introduced the notion of a measure of asymmetry. We use 
their axioms in the following definition. Other sets of axioms might be also reasonable from 
applications point of view.

A function $\mu : \mathcal{C} \rightarrow [0, \infty)$ is a measure of asymmetry (or a measure of non-exchangeability) 
for copula $C$ if it satisfies the following properties:

(B1): there exists $K \in [0, \infty)$ such that, for all $C \in \mathcal{C}$ we have $\mu(C) \leq K$,

(B2): $\mu(C) = 0$ if and only if $C$ is symmetric, i.e. $C = C^t$,

(B3): $\mu(C) = \mu(C^t)$ for every $C \in \mathcal{C}$,

(B4): $\mu(C) = \mu(\hat{C})$ for every $C \in \mathcal{C}$,

(B5): if $(C_n)_{n \in \mathbb{N}}$ and $C$ are in $\mathcal{C}$, and if $(C_n)_{n \in \mathbb{N}}$ converges uniformly to $C$, then $(\mu(C_n))_{n \in \mathbb{N}}$ 
converges to $\mu(C)$.

A large class of measures of asymmetry is provided in [7, Theorem 1]: Let $d_p$ be the classical 
$L_p$ distance in $\mathcal{C}$ for $p \in [1, \infty]$. When $p = \infty$, we have

$$d_\infty(C, D) = \max_{u, v \in \mathbb{I}} |C(u, v) - D(u, v)|.$$

Then, the measure of asymmetry $\mu_x : \mathcal{C} \rightarrow [0, \infty)$ is given by

$$\mu_x(C) = d_\infty(C, C^t).$$

Sometimes in the literature this measure is normalized to $3\mu_x$ (e.g. [3]).

In [24, §2], the so-called maximal asymmetry function is introduced; its value at a fixed point 
$(u, v) \in \mathbb{I}^2$ is given by

$$d_x^* (u, v) = \sup_{C \in \mathcal{F}} |C(u, v) - C(v, u)|,$$

where $\mathcal{F} \subseteq \mathcal{C}$ is an arbitrary family of copulas. If $\mathcal{F} = \mathcal{C}$ this supremum is attained since $\mathcal{C}$ is 
a compact set by [11, Theorem 1.7.7]. Klement and Mesiar [23] showed that

$$d_x^* (u, v) = \min\{u, v, 1 - u, 1 - v, |v - u|\}.$$

Confer also [28] where only $\leq$ inequality is established.

Now, choose $(a, b) \in \mathbb{I}^2$. Furthermore, choose a $c \in \mathbb{I}$ such that

$$0 \leq c \leq d_x^* (a, b).$$

According to [11, Theorem 1.4.5] the set $\mathcal{C}$ is convex, so it follows easily that there exits a 
copula $C \in \mathcal{C}$ such that

$$C(a, b) - C(b, a) = c.$$
Lemma 1. For any $c$ such that $0 \leq c \leq \min\{a, b, 1-a, 1-b\}$ functions

(4) \[ C^{(a,b)}_c(u,v) = \max\{W(u,v), \min\{d_1, u-a+d_1, v-b+d_1, u+v-a-b+d_1\}\}, \]

and

(5) \[ C^{(a,b)}_c(u,v) = \min\{M(u,v), \max\{d_2, u-b+d_2, v-a+d_2, u+v-a-b+d_2\}\}, \]

are copulas. Here $W$ respectively $M$ are the Fréchet Hoeffding lower bound respectively upper bound,

(6) \[ d_1 = d^{(a,b)}_{1,c} = W(a,b) + c \]

and

(7) \[ d_2 = d^{(a,b)}_{2,c} = M(a,b) - c. \]

Furthermore, the following relations hold:

(8) \[ C^{(a,b)}_c = (C^{(b,a)}_c)^t, \quad C^{(a,b)}_c = (C^{(b,a)}_c)^t, \]

(9) \[ C^{(a,b)}_c = (C^{(b,1-a)}_c)^{\sigma_1} = (C^{(1-b,a)}_c)^{\sigma_2}, \]

and

(10) \[ d^{(a,b)}_{2,c} = a - d^{(1-b,a)}_{1,c} = b - d^{(b,1-a)}_{1,c}. \]

Proof. Functions $C^{(a,b)}_c(u,v)$ and $C^{(a,b)}_c(u,v)$ are exactly copulas $C_L$ and $C_U$, respectively, given in [27, Theorem 3.2.3]. Observe that reflecting the scatterplot of $C^{(a,b)}_c(u,v)$ (see Figure 2) over the lines $x = \frac{1}{2}$ and $y = \frac{1}{2}$, respectively, gives the scatterplots of $C^{(1-a,b)}_c$ and $C^{(a,1-b)}_c$, respectively (see Figure 1). Thus equalities in (9) hold. A simple comparison of parameters also shows that the equalities in (10) hold. Finally, equalities in (8) follow if we reflect the two scatterplots in Figures 1 and 2 along the main diagonal of the unit square.

Figure 1. The surface of $C^{(a,b)}_c$ and its scatterplot
Observe that \( c \) is small enough so that everywhere close to the boundary of the square \( \mathbb{R}^2 \) copula \( W \) prevails in the definition of \( C_{c}^{(a,b)} \) and copula \( M \) prevails in the definition of \( C_{c}^{(a,b)} \). Note that \( C_{c}^{(a,b)} \) is a flipped shuffle of \( M \) (see [11, §3.6]) and \( C_{c}^{(a,b)} \) is a (straight) shuffle of \( M \). Observe also that condition \( c \in [0,d_1^*(a,b)] \) is stronger than the assumption \( 0 \leq c \leq \min\{a,b,1-a,1-b\} \) on \( c \) in Lemma [1]. Then, equality (3) fails for \( c \) such that \( 0 \leq c \leq \min\{a,b,1-a,1-b\} \) but \( c > |b-a| \).

**Theorem 2.** For any \( c \in [0,d_1^*(a,b)] \) there exist copulas \( C, \overline{C} \) satisfying Condition (3) such that for every copula \( C \) satisfying (3) we have \( C \leq C \leq \overline{C} \).

**Proof.** We use the copulas introduced in Lemma [1]. We write \( C(u, v) = C_{c}^{(a,b)}(u, v) \) and \( \overline{C}(u, v) = C_{c}^{(a,b)}(u, v) \). Note that \( d_1 \) and \( d_2 \) are given in (6) and (7), respectively. It is clear that \( C \) satisfies Condition (3), since \( C(b, a) = W(b, a) \) and \( C(a, b) = d_1 = W(a, b) + c \). The fact that \( \overline{C} \) satisfies this condition goes similarly using the definition of \( d_2 \).
Suppose that \( C \) is a copula satisfying (3). Let us now show that \( \underline{C} \leq C \). It is clear that 
\[
C(p, b, a) = W(p, b, a) + c = W(a, b) + c = \underline{C}(a, b) = d_1.
\]
The general proof will be given in 5 cases, corresponding to the areas, shown in Figure 3.

Case 0: If \( p, u, v \) does not belong to any of the sets 1, 2, 3, or 4, then \( C = \underline{C} \) and we are done.

Case 1: \( a \geq u, b \geq v, a + b - d_1 \leq u + v \). Here \( C(u, v) = u + v - a - b + d_1 \). Since 
\[
C(a, v) - C(u, v) \leq a - u
\]
by the 1-Lipschitz property, and 
\[
C(a, b) - C(a, v) \leq b - v
\]
by the same property, it follows that 
\[
C(u, v) \geq C(a, v) - (a - u) \geq C(a, b) - (a - u) - (b - v) \geq d_1 - (a - u) - (b - v) = \underline{C}(u, v),
\]
where we have also used (11).

Case 2: \( a \leq u \leq 1 - b + d_1, b - d_1 \leq v \leq b \). Here \( C = v - b + d_1 \), so that 
\[
C(u, v) \geq C(a, v) \geq C(a, b) - (b - v) \geq \underline{C}(u, v),
\]
where we have used respectively the 1-increasing property, the 1-Lipschitz property, and (11).

Case 3: \( a \leq u, b \leq v, a + b - d_1 \geq u + v \). Here \( C = d_1 \), so that 
\[
C(u, v) \geq C(a, b) \geq d_1 = \underline{C}(u, v),
\]
where in the first inequality we used twice the 1-increasing property, and in the second one we used (11).

Case 4: \( a - d_1 \leq u \leq a, b \leq v \leq 1 - a + d_1 \). Here \( C = u - a + d_1 \), so that 
\[
C(u, v) \geq C(u, b) \geq C(a, b) - (a - u) \geq \underline{C}(u, v).
\]

In the displayed considerations we used the 1-increasing property, the 1-Lipschitz property and then (11).

Finally, we show that \( C \leq \overline{C} \). We first observe that \( \overline{C}(b, a) = d_2 \) and \( \overline{C}(a, b) = M(a, b) \) so that the desired property is valid for the two “central” points; and then, as above, we use the 5 cases of sections where \( \overline{C} \) is either equal to copula \( M \) or a simple plane in order to get the property in general.

Observe that the two copulas \( \overline{C}_{c}^{(a,b)} \) and \( \overline{C}_{c}^{(a,b)} \) are the exact lower, respectively upper, bound of all asymmetric copulas that satisfy (3). We call these copulas local Fréchet-Hoeffding bounds.

**Example 3.** Observe that for \( a = 0.4, b = 0.6 \) and \( c = 0.1 \) we have that \( \overline{C}_{c}^{(a,b)} \leq \Pi \leq \overline{C}_{c}^{(a,b)} \). Hence the set of all copulas \( C \) such that \( \overline{C}_{c}^{(a,b)} \leq C \leq \overline{C}_{c}^{(a,b)} \) is not in general the same as the set of all copulas \( C \) such that \( C(a, b) - C(b, a) = c \).
3. Preliminaries on measures of concordance

A pair of random vectors \((X_1, X_2)\) and \((Y_1, Y_2)\) is concordant if larger values of the first one are associated with larger values of the second one, while smaller values of the first one are associated with smaller values of the second. The opposite notion is the notion of discordance. A pair of random vectors is discordant if larger values for the first one are associated with smaller values of the second one, while smaller values of the first one are associated with larger values of the second. With this in mind, we denote by \(\mathcal{Q}\) (see [27, §5.1] or [11, §2.4]) the difference of two probabilities \(\mathcal{Q} = P((X_1 - X_2)(Y_1 - Y_2) > 0) - P((X_1 - X_2)(Y_1 - Y_2) < 0)\) for a pair of continuous random vectors \((X_1, X_2)\) and \((Y_1, Y_2)\). If the corresponding copulas are \(C_1\) and \(C_2\) then we have

\[
Q = Q(C_1, C_2) = 4 \int_{\mathbb{R}^2} C_2(u, v) dC_1(u, v) - 1.
\]

See [27, Theorem 5.1.1]. Function \(Q\) is called the concordance function. It was introduced by Kruskal [25]. This function has a number of useful properties [27, Corollary 5.1.2]:

(Q1): It is symmetric in the two arguments: \(Q(C_1, C_2) = Q(C_2, C_1)\).

(Q2): It is nondecreasing in each argument: If \(C_1 \leq C_1'\) and \(C_2 \leq C_2'\) then \(Q(C_1, C_2) \leq Q(C_1', C_2')\) and \(Q(C_1, C_2) \leq Q(C_1, C_2')\).

(Q3): It remains unchanged when both copulas are replaced by their survival copulas:

\[
Q(C_1, C_2) = Q(\widehat{C}_2, \widehat{C}_1).
\]

Next, we state an additional property of \(Q\) that is probably well-known but we could not find it stated in the form we use later. It is known that the dihedral group \(D_4\) acts on \(\mathcal{C}\) via transposition and reflections (see, e.g., [12, Table 2.1]). The direct orbit of this action on a given copula \(C \in \mathcal{C}\) is \(\{C, \widehat{C}, C', \widehat{C}'\}\) and its opposite orbit is \(\{C^{\sigma_1}, C^{\sigma_2}, (C')^{\sigma_1}, (C')^{\sigma_2}\}\). The concordance function is invariant under the direct action on both arguments, while the opposite action changes the sign. The former follows by (Q2) and simple observation that \(Q(C_1, C_2) = Q(C'_1, C'_2)\) holds since the value of the integral in (12) remains the same if we exchange \(u\) and \(v\). To see the latter we recall [12, Lemma 2.3], where it is proved that

\[
\int_{\mathbb{R}^2} C_2(u, v) dC_1(u, v) + \int_{\mathbb{R}^2} C_2^v(u, v) dC_1(u, v) = \frac{1}{2} \quad \text{for } j = 1, 2.
\]

A straightforward consequence of (13) is the following property of the concordance function:

(Q4): When both copulas are replaced by their reflected copulas the sign changes:

\[
Q(C_1^{\sigma_j}, C_2^{\sigma_j}) = -Q(C_1, C_2) \quad \text{for } j = 1, 2.
\]

Note that since reflection is an involution Property (Q4) can be restated also in the form \(Q(C_1^{\sigma_j}, C_2) = -Q(C_1, C_2^{\sigma_j})\) for \(j = 1, 2\).

A mapping \(\kappa : \mathcal{C} \to [-1, 1]\) is called a measure of concordance if it satisfies the following properties (see [27, Definition 5.1.7]):

(C1): \(\kappa(M) = 1\).

(C2): \(\kappa(C) = \kappa(C')\) for every \(C \in \mathcal{C}\).

(C3): \(\kappa(C) \leq \kappa(D)\) when \(C \leq D\).

(C4): \(\kappa(C^{\sigma_1}) = \kappa(C^{\sigma_2}) = -\kappa(C)\).
(C5): If a sequence of copulas $C_n$, $n \in \mathbb{N}$, converges uniformly to $C \in \mathcal{C}$, then $\lim_{n \to \infty} \kappa(C_n) = \kappa(C)$.

We will refer to property (C5) above simply by saying that a measure of concordance under consideration is monotone.

Observe that some more properties that are sometimes stated in the definition follow from the properties listed above. Namely, we also have that a measure of concordance satisfies the following:

(C6): $\kappa(\Pi) = 0$, where $\Pi$ is the independence copula $\Pi(u,v) = uv$.

(C7): $\kappa(W) = -1$.

(C8): $\kappa(C) = \kappa(\hat{C})$ for every $C \in \mathcal{C}$.

Property (C4) implies Property (C6) since $\Pi$ is invariant under both reflections, Property (C7) since $W = (M)^{\sigma_1}$, and Property (C8) since $\hat{C} = (C^{\sigma_1})^{\sigma_2}$.

Note that properties (C2), (C4) and (C8) can be expressed also in terms of the $D_4$ action on $\mathcal{C}$. Thus, a measure of concordance leaves a direct orbit of a copula $C \in \mathcal{C}$ invariant, while it changes sign on the opposite orbit.

Because of their significance in statistical analysis measures of concordance and their relatives measures of association and measures of dependence are a classical topic of research. It was Scarsini [33] who introduced formal axioms of a measure of concordance. Some of more recent references on bivariate measures of concordance include [14, 16, 18, 26, 29, 30]. Their multivariate generalization were studied e.g. in [2, 6, 35, 36]. For bivariate copulas the main measures of concordance are naturally studied through symmetries that are consequence of properties (Q1), (Q3) and (Q4) of the concordance function $Q$ (see for instance [1, 12, 13]).

The four most commonly used measures of concordance of a copula $C$ are Kendall’s tau, Spearman’s rho, Gini’s gamma and Blomqvist’s beta. We refer to [26] for an extended definition of a measure of concordance. Roughly, if we replace Property (C4) by Property (C6) we get what Liebscher in [26] calls a weak measure of concordance. Spearman’s footrule is an example of such a weak measure of concordance. To simplify the statements from now on, we refer simply as measures of concordance to all five of measures studied: Kendall’s tau, Spearman’s rho, Gini’s gamma, Blomqvist’s beta, and Spearman’s footrule. Statistical significance of all five measures is already well established. See e.g. [27, Ch. 5] for Kendall’s tau, Spearman’s rho, and e.g. [20, 36] for Gini’s gamma, Blomqvist’s beta and Spearman’s footrule.

The first four of the measures of concordance may be defined in terms of the concordance function $Q$. Kendall’s tau of $C$ is defined by

\[ \tau(C) = Q(C,C), \]

Spearman’s rho by

\[ \rho(C) = 3Q(C,\Pi), \]

Gini’s gamma by

\[ \gamma(C) = Q(C,M) + Q(C,W). \]
Spearman’s footrule by
\[ \phi(C) = \frac{1}{2} (3Q(C, M) - 1). \]

On the other hand, Blomqvist’s beta is defined by
\[ \beta(C) = 4C \left( \frac{1}{2}, \frac{1}{2} \right) - 1. \]

See [11 §2.4] and [27 Ch. 5] for further details.

4. Concordance function evaluated at the local Fréchet-Hoeffding bounds

In what follows we will need the values of the concordance function \( Q \) applied to a pair of copulas one of which will be lower bound \( C_{(a,b)} \) respectively upper bound \( C_{(a,b)}' \) defined by (1) respectively by (5). Observe that these copulas are flipped and straight shuffles of \( M \) [11, p. 103] respectively (see Figures 1 and 2). A short computation then reveals that

\[
Q(D, C_{(a,b)}) = 4 \int D(u, v) dC_{(a,b)}(u, v) - 1 = \\
= 4 \int_0^{a-d_1} D(u, 1 - u)du + 4 \int_{a-d_1}^{a} D(u, a + b - d_1 - u)du + \\
+ 4 \int_{a}^{1-b+d_1} D(u, 1 + d_1 - u)du + 4 \int_{1-b+d_1}^{1} D(u, 1 - u)du - 1
\]

respectively

\[
Q(D, C_{(a,b)}') = 4 \int D(u, v) dC_{(a,b)}'(u, v) - 1 = \\
= 4 \int_0^{a-b+d_2} D(u, u)du + 4 \int_{d_2}^{b} D(u, u + a - d_2)du + \\
+ 4 \int_{b}^{a+b-d_2} D(u, u - b + d_2)du + 4 \int_{a+b-d_2}^{1} D(u, u)du - 1.
\]

To compute the values of various measures of concordance we need the above values of \( Q \) for various copulas \( D: W, \Pi, M, \) and \( C_{(a,b)} \), respectively \( C_{(a,b)}' \). Recall that \( d_1 = d_{1,c}^{(a,b)} \) is given by (6).

Proposition 4. Let \( (a, b) \in \Gamma^2 \) and \( 0 \leq c \leq \min\{a, b, 1 - a, 1 - b\} \). For copulas \( C_{(a,b)} \) it holds:

1. \( Q(W, C_{(a,b)}) = 4d_1(1 - a - b + d_1) - 1 \),
2. \( Q(\Pi, C_{(a,b)}) = 2d_1(1 - a - b + d_1)(1 - a - b + 2d_1) - \frac{1}{3} \).
\[(3) \quad Q(M, C_x^{(a,b)}) =
\begin{cases}
0; & \text{if } b \geq d_1 + \frac{1}{2}, \\
(2d_1 + 1 - 2b)^2; & \text{if } \frac{1}{2}(1 + d_1) \leq b \leq d_1 + \frac{1}{2}, a \leq b - d_1, \\
(a + b - 1 - d_1)(3b - 3d_1 - a - 1); & \text{if } \frac{1}{2}(1 + d_1) < b \leq d_1 + \frac{1}{2}, a \geq b - d_1, \\
d_1(2 + 3d_1 - 4b); & \text{if } b \leq \frac{1}{2}(1 + d_1), a \leq b - d_1, \\
2d_1(1 + d_1 - a - b) - (a - b)^2; & \text{if } d_1 \geq 2a - 1, d_1 \geq 2b - 1, d_1 \geq a - b, d_1 \geq b - a, \\
d_1(2 + 3d_1 - 4a); & \text{if } a \leq \frac{1}{2}(1 + d_1), b \leq a - d_1, \\
(a + b - 1 - d_1)(3a - 3d_1 - b - 1); & \text{if } \frac{1}{2}(1 + d_1) \leq a \leq d_1 + \frac{1}{2}, b \geq a - d_1, \\
(2d_1 + 1 - 2a)^2; & \text{if } \frac{1}{2}(1 + d_1) < a \leq d_1 + \frac{1}{2}, b \leq a - d_1, \\
0; & \text{if } a \geq d_1 + \frac{1}{2},
\end{cases}
\]

\[(4) \quad Q(C_x^{(a,b)}, C_x^{(a,b)}) = 4d_1(1 - a - b + d_1) - 1.
\]

Proof. 

(1) Observe that \(W(u, 1 - u) = W(u, a + b - d_1 - u) = 0\), so the first, the second and the fourth integral in (19) are zero. Further, \(W(u, 1 + d_1 - u) = d_1\), hence \(Q(W, C_x^{(a,b)}) = 4d_1(1 - a - b + d_1) - 1\).

(2) Observe that \(\Pi(u, a + b - d_1 - u) = u(a + b - d_1 - u) = u(1 - u) + ud_1\). Hence \(Q(\Pi, C_x^{(a,b)}) = 4 \int_0^1 u(1 - u)du + 4 \int_{a-d_1}^a u(a + b - d_1 - 1)du + 4 \int_{a}^{1-b+d_1} ud_1 du - 1 = 2d_1(1 - a - b + d_1)(1 - a - b + 2d_1) - \frac{1}{3}\). 

(3) The value of \(Q(M, C_x^{(a,b)})\) depends on where the vertices \(P(a, b - d_1), Q(1 - b + d_1, b - d_1), R(1 - b + d_1, b), S(a, 1 - a + d_1), T(a - d_1, 1 - a + d_1), \) and \(U(a - d_1, b)\) of the hexagon \(PQRSTU\) lie with respect to the main diagonal \(u = v\) (see Figure 4).

**Figure 4.** The hexagon \(PQRSTU\)

We consider several cases.

(a) All the vertices lie above the main diagonal, which holds as soon as \(Q\) lies above the main diagonal. It means that \(b \geq d_1 + \frac{1}{2}\). In this case in the first, the second
and the third integral of (19) we have $M(u, v) = u$, while for the fourth integral we have $M(u, v) = u$ for $u \in [1 - b + d_1, \frac{1}{2}]$ and $M(u, v) = 1 - u$ for $u \in [\frac{1}{2}, 1]$, so that

$$Q(M, C^{(a, b)}) = 4 \int_0^{\frac{1}{2}} u \, du + 4 \int_{\frac{1}{2}}^1 (1 - u) \, du - 1 = 0.$$  

(b) $Q$ lies below the main diagonal, and all other vertices lie above the main diagonal, which holds as soon as $P$ and $R$ lie above the main diagonal. It means that $rac{1}{2}(1 + d_1) \leq b \leq d_1 + \frac{1}{2}, a \leq b - d_1$. In this case again, we have $M(u, v) = u$ in the first, the second and the third integral of (19), while in the fourth integral we have $M(u, v) = v$. Then it follows that

$$Q(M, C^{(a, b)}) = 4 \int_0^{1 - b + d_1} u \, du + 4 \int_{1 - b + d_1}^1 (1 - u) \, du - 1 = (2d_1 + 1 - 2b)^2.$$  

(c) $P$ and $Q$ lie below the main diagonal, and all other vertices lie above the main diagonal. It means that $\frac{1}{2}(1 + d_1) \leq b \leq d_1 + \frac{1}{2}, a \geq b - d_1$. In this case we have $M(u, v) = u$ in the first and the third integral of (19), we have $M(u, v) = v$ in the fourth integral, while the second integral splits into two parts

$$\int_{a - d_1}^a M(u, a + b - d_1 - u) \, du = \int_{a - d_1}^{\frac{a}{2} + (a - b - d_1)} u \, du + \int_{\frac{a}{2} + (a - b - d_1)}^a (a + b - d_1 - u) \, du,$$

so that

$$Q(M, C^{(a, b)}) = 4 \int_0^{\frac{a}{2} + (a - b - d_1)} u \, du + 4 \int_{\frac{a}{2} + (a - b - d_1)}^{a} (a + b - d_1 - u) \, du +$$

$$+ 4 \int_a^{1 - b + d_1} u \, du + 4 \int_{1 - b + d_1}^1 (1 - u) \, du - 1 =$$

$$= (a + b - 1 - d_1)(3b - 3d_1 - a - 1).$$  

(d) $Q$ and $R$ lie below the main diagonal, and all other vertices lie above the main diagonal. It means that $b \leq \frac{1}{2}(1 + d_1), a \leq b - d_1$. In this case in the first and the second integral of (19) we have $M(u, v) = u$, in the fourth we have $M(u, v) = v$, and the third integral splits into two parts

$$\int_a^{1 - b + d_1} M(u, 1 + d_1 - u) \, du = \int_a^{\frac{a}{2} + (1 + d_1)} u \, du + \int_{\frac{a}{2} + (1 + d_1)}^{1 - b + d_1} (1 + d_1 - u) \, du,$$

so that

$$Q(M, C^{(a, b)}_c) = 4 \int_0^{\frac{a}{2} + (1 + d_1)} u \, du + 4 \int_{\frac{a}{2} + (1 + d_1)}^{1 - b + d_1} (1 + d_1 - u) \, du +$$

$$+ 4 \int_{1 - b + d_1}^1 (1 - u) \, du - 1 =$$

$$= d_1(2 + 3d_1 - 4b).$$
Proposition 5. Let \((a, b) \in \mathbb{I}^2\) and \(0 \leq c \leq \min\{a, b, 1 - a, 1 - b\}\). For copulas \(\overline{C}_c^{(a, b)}\) it holds:

1. \(Q(W, \overline{C}_c^{(a, b)}) = 0; \) if \(a + b - \frac{1}{2} \leq d_2\),

\[
\begin{align*}
-2(a + 2b - 2d_2 - 2); \\
-(a - d_2)(a + 3d_2 - 2); \\
(b - d_2)(b + 3d_2 - 2); \\
-(1 - 2d_2)^2; \\
0;
\end{align*}
\]

\(\frac{1}{3} - 2(a + b - 2d_2)(a - d_2)(b - d_2)\),

2. \(Q(\Pi, \overline{C}_c^{(a, b)}) = \frac{1}{3} - 2(a + b - 2d_2)(a - d_2)(b - d_2)\),

3. \(Q(M, \overline{C}_c^{(a, b)}) = 1 - 4(a - d_2)(b - d_2)\),

\(d_2 \leq \min\{1 - a, 1 - b, 2a + b - 1, a + 2b - 1\}\),

\(d_2 \leq \max\{2a + b - 1, a + 2b - 1\} \leq d_2 \leq a + b - \frac{1}{2}\),

\(d_2 \leq \max\{a + 2b - 1, 2a + b - 1\} \leq d_2 \leq a + b - 1\),

\(d_2 \leq 1 - b\),

\(d_2 \leq 1 - a\),

\(d_2 \leq \frac{1}{2}\),

\(d_2 \leq \frac{1}{2}\).
(4) $Q(C_c^{(a,b)}, C_c^{(a,b)}) = 1 - 4(a - d_2)(b - d_2)$.

**Proof.** To prove the proposition we use Property (Q4) of the concordance function, Lemma 1 and Proposition 4. More precisely, equalities (Q4), (9), Proposition 4, and (10) are applied in succession in each of the following three calculations:

$$Q(II, C_c^{(a,b)}) = -Q(II, C_c^{(b,1-a)})$$
$$= \frac{1}{3} - 2d_{1,c}^{(b,1-a)} \left(1 - a - b + d_{1,c}^{(b,1-a)}\right) \left(1 - a - b + 2d_{1,c}^{(b,1-a)}\right)$$
$$= \frac{1}{3} - 2(a - d_2)(b - d_2)(a + b - 2d_2),$$

$$Q(M, C_c^{(a,b)}) = -Q(W, C_c^{(b,1-a)})$$
$$= 1 - 4d_{1,c}^{(b,1-a)} \left(1 - a - b + d_{1,c}^{(b,1-a)}\right)$$
$$= 1 - 4(a - d_2)(b - d_2),$$

and

$$Q(C_c^{(a,b)}, C_c^{(a,b)}) = -Q(C_c^{(b,1-a)}, C_c^{(b,1-a)})$$
$$= 1 - 4d_{1,c}^{(b,1-a)} \left(1 - a - b + d_{1,c}^{(b,1-a)}\right)$$
$$= 1 - 4(a - d_2)(b - d_2).$$

Thus we proved (2), (3) and (4).

To prove (1) we use the same arguments, but a more detailed case by case analysis is required. We omit the details. □

It turns out that the results obtained in Propositions 4 and 5 are symmetric with respect to the main diagonal and to the counter-diagonal. The proofs follow directly from Lemma 1 using Properties (Q1), (Q3) and (Q4) of the concordance function.

**Proposition 6.** Let $(a, b) \in \mathbb{R}^2$ and $0 \leq c \leq \min\{a, b, 1 - a, 1 - b\}$. Then the following holds for any $D \in \{W, II, M\}$:

1. $Q(D, C_c^{(a,b)}) = Q(D, C_c^{(b,a)})$ and $Q(D, C_c^{(a,b)}) = Q(D, C_c^{(b,a)})$.
2. $Q(D, C_c^{(a,b)}) = Q(D, C_c^{(1-a,1-b)})$ and $Q(D, C_c^{(a,b)}) = Q(D, C_c^{(1-a,1-b)})$.
3. $Q(D, C_c^{(a,b)}) = -Q(D, C_c^{(b,1-a)})$ and $Q(D, C_c^{(a,b)}) = -Q(D, C_c^{(b,1-a)})$.
4. $Q(C_c^{(a,b)}, C_c^{(a,b)}) = Q(C_c^{(b,a)}, C_c^{(b,a)})$ and $Q(C_c^{(a,b)}, C_c^{(a,b)}) = Q(C_c^{(b,a)}, C_c^{(b,a)})$.
5. $Q(C_c^{(a,b)}, C_c^{(a,b)}) = Q(C_c^{(1-a,1-b)}, C_c^{(1-a,1-b)})$ and $Q(C_c^{(a,b)}, C_c^{(a,b)}) = Q(C_c^{(1-a,1-b)}, C_c^{(1-a,1-b)})$.
6. $Q(C_c^{(a,b)}, C_c^{(a,b)}) = -Q(C_c^{(b,1-a)}, C_c^{(b,1-a)})$ and $Q(C_c^{(a,b)}, C_c^{(a,b)}) = -Q(C_c^{(b,1-a)}, C_c^{(b,1-a)})$.

We now prove the crucial lemma which will enable us to find the relations between measures of concordance and asymmetry.
Let $C \in \mathcal{C}$ be any copula with $\mu_{\infty}(C) = m$ and $\kappa \in \{\rho, \tau, \phi, \gamma\}$ a measure of concordance. By the definition of asymmetry there exists a pair $(a_0, b_0) \in \mathbb{I}^2$ such that
$$|C(a_0, b_0) - C(b_0, a_0)| = m.$$ Here we may choose with no loss that $a_0 \leq b_0$ due to the fact that the considered measures of concordance are invariant with respect to the symmetry by Proposition 6(1). However, the expression between vertical bars may be positive or negative. In the case of negative value we replace $C$ with $C^t$, hence we may assume that $C(a_0, b_0) - C(b_0, a_0) \leq m$. It follows from Theorem 2 that
$$C_{m}^{(a_0, b_0)} \leq C \leq C_{m}^{(b_0, a_0)}$$ and by monotonicity of $\kappa$ we have that
$$\kappa(C_{m}^{(a_0, b_0)}) \leq \kappa(C) \leq \kappa(C_{m}^{(b_0, a_0)}) .$$
We fix $m$ and we denote by $\Delta RST$ a triangle within the square $\mathbb{I}^2$ such that
$$\Delta RST = \{(a, b) \in \mathbb{I}^2; a \leq b, d_C^*(a, b) \geq m\}.$$ Since $C(a_0, b_0) - C(b_0, a_0) = m \geq 0$ it must be that $(a_0, b_0) \in \Delta RST$. It can be verified easily that
$$\Delta RST = \{(a, b) \in \mathbb{I}^2; a \geq m, b \leq 1 - m, b - a \geq m\}$$ with the vertices $R(m, 2m), S(1 - 2m, 1 - m)$ and $T(m, 1 - m)$. Denote by $U(\frac{1}{2}(1 - m), \frac{1}{2}(1 + m))$ the center of the edge $RS$, see Figure 5. Define $\Delta_m := \Delta RUT$.

![Figure 5. The triangle $\Delta_m$](image)

It follows that
$$\kappa(C) \in \left[ \min_{(a, b) \in \Delta RST} \kappa(C_{m}^{(a, b)}), \max_{(a, b) \in \Delta RST} \kappa(C_{m}^{(a, b)}) \right].$$ Due to Proposition 6 the minimum and the maximum can be taken over $\Delta_m$ instead of $\Delta RST$.

**Lemma 7.** Let $C \in \mathcal{C}$ be any copula with $\mu_{\infty}(C) = m$ and $\kappa \in \{\rho, \tau, \phi, \gamma\}$ a measure of concordance. Then

(21) $$\kappa(C) \in \left[ \min_{(a, b) \in \Delta_m} \kappa(C_{m}^{(a, b)}), \max_{(a, b) \in \Delta_m} \kappa(C_{m}^{(a, b)}) \right].$$
Note that either max in (21) can be replaced by min or min by max if we use relation (9), and Properties (C2) and (C4). For instance, we have
\[
\max_{(a,b)\in \Delta_m} \kappa(C_m^{(a,b)}) = \max_{(a,b)\in \Delta_m} \left(-\kappa(C_m^{(1-b,a)})\right)
\]
\[
= - \min_{(a,b)\in \Delta_m} \left(\kappa(C_m^{(a,1-b)})\right)
\]
\[
= - \min_{(a,b)\in \Delta_m} \left(\kappa(C_m^{(a,b)})\right),
\]
where \(\Delta_m^a = \{(a,b) \in I^2; a \geq m, b-a \geq 0, a+b \leq 1-m\}\). Observe however, that copulas \(C_m^{(a,b)}\) appearing in the minimum of (22) do not need to satisfy (3). We do not consider such copulas in the proofs of the following sections.

5. Relations between Spearman’s rho and asymmetry

To find the relations between Spearman’s rho and asymmetry, we compute minimum and maximum from (21) for \(\kappa = \rho\).

**Lemma 8.** (a): \(\min_{(a,b)\in \Delta_m} \rho(C_m^{(a,b)}) = \rho(C_m^{(m,1-m)}) = 12m^3 - 1\)

(b): \(\max_{(a,b)\in \Delta_m} \rho(C_m^{(a,b)}) = \rho(C_m^{(m,2m)}) = 1 - 36m^3\).

**Proof.** (a): Recall that \(\rho(C) = 3Q(C, \Pi)\). Take \((a,b) \in \Delta_m\). Since \(a+b \leq 1\), we have \(W(a,b) = 0\), so \(d_1 = m + W(a,b) = m\) and by Proposition 4 we get that
\[
\rho(C_m^{(a,b)}) = 3Q(\Pi, C_m^{(a,b)}) = 6m(1-a-b+m)(1-a-b+2m) - 1.
\]
We look at this expression as a quadratic function of \(x = a+b\), with \(x \in [3m,1]\). Then
\[
f(x) := \rho(C_m^{(a,b)}) = 6m(x^2 - (3m+2)x + 2m^2 + 3m + 1) - 1.
\]
Its minimum is attained at a point \(x = \frac{3}{2}m + 1 \notin [3m,1]\), hence our optimal value appears at \(x = 1 = a+b\). Thus \(\rho(C_m^{(a,b)})\) takes its minimal value \(f(1) = 12m^3 - 1\) on the entire line segment \(UT\), in particular at \((a,b) = (m,1-m)\).

(b): Since the triangle \(\Delta_m\) lies above the main diagonal, we have \(M(a,b) = a\), thus \(d_2 = M(a,b) - m = a - m\). By Proposition 5
\[
\rho(C_m^{(a,b)}) = 3Q(\Pi, C_m^{(a,b)}) = 1 - 6(a+b-d_2)(a-d_2)(b-d_2) = 1 - 6m(b-a+2m)(b-a+m).
\]
We look at this expression as a quadratic function of \(x = b-a\), with \(x \in [m,1-2m]\). Then
\[
g(x) := \rho(C_m^{(a,b)}) = 1 - 6m(x^2 + 3mx + 2m^2).
\]
Its maximum is attained at a point \(x = -\frac{3}{2}m \notin [m,1-2m]\), hence our optimal value appears at \(x = m = b-a\). Thus \(\rho(C_m^{(a,b)})\) takes its maximal value \(g(m) = 1 - 36m^3\) on the entire line segment \(RS\), in particular at \((a,b) = (m,2m)\). \(\square\)

We collect our findings in the main theorem of this section.
Theorem 9. Let $C \in \mathcal{C}$ be any copula with $\mu_x(C) = m$. Then

$$\rho(C) \in [12m^3 - 1, 1 - 36m^3]$$

and any value from this interval can be attained. In particular, if copula $C$ is symmetric, then $\rho(C)$ can take any value in $[-1, 1]$. If copula $C$ takes the maximal possible asymmetry $\mu_x(C) = \frac{1}{3}$, then $\rho(C) \in [-\frac{5}{9}, -\frac{1}{3}]$.

Proof. It remains to be proved only that any value from the interval $[12m^3 - 1, 1 - 36m^3]$ can be attained. First notice that a convex combination $C = tC_m^{(a,b)} + (1 - t)C_m^{(a,b)}$ is a copula with asymmetry $m$ for any $t \in [0, 1]$. Since $\rho$ is polynomial in $t$ [14, p. 1778] it then follows that the image of $\rho$ on the set of all copulas with asymmetry $m$ is a closed interval.

Using inverse functions, the following corollary immediately follows. Figure 6 shows these relations.

Corollary 10. If $\rho(C) = \rho$, then

$$0 \leq \mu_x(C) \leq \begin{cases} \sqrt[3]{\frac{1 + \rho}{12}}; & -1 \leq \rho \leq -\frac{5}{9}, \\ \frac{1}{3}; & -\frac{5}{9} \leq \rho \leq -\frac{1}{3}, \\ \sqrt[3]{\frac{1 - \rho}{36}}; & -\frac{1}{3} \leq \rho \leq 1, \end{cases}$$

and the bounds are attained.

Figure 6. Relations between Spearman’s rho and asymmetry
6. Relations between Kendall’s tau and asymmetry

To find the relations between Kendall’s tau and asymmetry, we compute minimum and maximum from \( \kappa = \tau \).

**Lemma 11.** (a): \[ \min_{(a,b) \in \Delta_m} \tau(C_m^{(a,b)}) = \tau(C_m^{(m,1-m)}) = 4m^2 - 1 \]

(b): \[ \max_{(a,b) \in \Delta_m} \tau(C_m^{(a,b)}) = \tau(C_m^{(m,2m)}) = 1 - 8m^2. \]

**Proof.** (a): Recall that \( \tau(C) = Q(C,C) \). For \( (a,b) \in \Delta_m \) we have by Proposition 4 that

\[ \tau(C_m^{(a,b)}) = 4m(1 - a - b + m) - 1. \]

This is a linear function of \( x = a - b \) for \( x \in [3m,1] \), which takes its minimum at \( x = 1 \), which corresponds to \( a + b = 1 \). Thus \( \tau(C_m^{(a,b)}) \) takes its minimal value \( 4m^2 - 1 \) on the entire line segment \( UT \), in particular at \( (a,b) = (m,1-m) \).

(b): Since the triangle \( \Delta_m \) lies above the main diagonal, we have \( d_2 = a - m \). We use Proposition 5 to obtain that

\[ \tau(C_m^{(a,b)}) = 1 - 4(a - d_2)(b - d_2) = 1 - 4m(b - a + m). \]

This a linear function of \( x = b - a \) for \( x \in [m,1-2m] \), which takes its maximum at \( x = m \), which corresponds to \( b = a + m \). Thus \( \tau(C_m^{(a,b)}) \) takes its maximal value on the entire line segment \( RS \), in particular at \( (a,b) = (m,2m) \), where \( \tau(C_m^{(m,2m)}) = 1 - 8m^2. \)

Using the same argument as in section 5, we get the main theorem of this section and its corollary. Figure 7 shows the relations between Kendall’s tau and asymmetry.

**Theorem 12.** Let \( C \in \mathcal{C} \) be any copula with \( \mu_x(C) = m \). Then

\[ \tau(C) \in [4m^2 - 1, 1 - 8m^2] \]

and any value from this interval can be attained. In particular, if copula \( C \) is symmetric, then \( \rho(C) \) can take any value in \( [-1,1] \). If copula \( C \) takes the maximal possible asymmetry \( \mu_x(C) = \frac{1}{3} \), then \( \rho(C) \in [-\frac{5}{9}, \frac{1}{9}] \).

**Corollary 13.** If \( \tau(C) = \tau \), then

\[ 0 \leq \mu_x(C) \leq \begin{cases} \sqrt{\frac{1 + \tau}{4}} ; & -1 \leq \tau \leq -\frac{5}{9}, \\ \frac{1}{3} ; & -\frac{5}{9} \leq \tau \leq \frac{1}{9}, \\ \sqrt{\frac{1 - \tau}{8}} ; & \frac{1}{9} \leq \tau \leq 1, \end{cases} \]

and the bounds are attained.
7. Relations between Spearman’s Footrule and Asymmetry

To find the relations between Spearman’s footrule and asymmetry, we compute minimum and maximum from (21) for \( \kappa = \phi \). Recall that \( \phi(\kappa) = \phi(C_m) \). Let us denote by \( m \) the central point of the hexagon.

Lemma 14. (a) \( \min_{(a,b) \in \Delta_m} \phi(C'_m^{(a,b)}) = \phi(C'_m^{(m,1-m)}) = \begin{cases} \frac{1}{2}; & \text{if } 0 \leq m \leq \frac{1}{4}, \\ 24m^2 - 12m + 1; & \text{if } \frac{1}{4} \leq m \leq \frac{1}{3}. \end{cases} \)

(b) \( \max_{(a,b) \in \Delta_m} \phi(C'_m^{(a,b)}) = \phi(C'_m^{(m,1)}) = 1 - 12m^2. \)

Proof. (a): For \( (a,b) \in \Delta_m \) in the expression for \( Q(M,C'_m^{(a,b)}) \) only three out of nine cases are possible, namely, the first, the second and the fourth. In the third case, when the vertex \( P \) of the hexagon is below the main diagonal and \( R \) is above it (see Figure 4), the central point \( (a,b) \) is above the counter-diagonal. In the remaining four cases we have the central point below the main diagonal. Since in the triangle \( \Delta_m \), we have \( d_1 = W(a,b) + m \) and \( b - a \geq m \) the expression for \( Q(M,C'_m^{(a,b)}) \) simplifies to

\[
Q(M,C'_m^{(a,b)}) = \begin{cases} 0; & \text{if } m + \frac{1}{2} \leq b, \\ (2m + 1 - 2b)^2; & \text{if } \frac{1}{2}(1 + m) \leq b \leq m + \frac{1}{2}, \\ m(2 + 3m - 4b); & \text{if } b \leq \frac{1}{2}(1 + m). \end{cases}
\]

For fixed \( m \) it depends only on \( b \), and we need to minimize it for \( b \in [2m, 1-m] \). Notice that for big values of \( m \) (i.e. close to \( \frac{1}{3} \)) not all of three cases are possible. Regardless of that, the left part, when \( b \leq \frac{1}{2}(1 + m) \), is linear and decreasing in \( b \), the middle part, when \( \frac{1}{2}(1 + m) \leq b \leq m + \frac{1}{2} \) is quadratic and also decreasing in \( b \), since \( \frac{d}{db}(2m + 1 - 2b)^2 = -4(2m + 1 - 2b) \leq 0, \)
and the right part is constant. So, \( \phi(C_{m}^{(a,b)}) \) takes its minimal value for \( b = 1 - m \), i.e. at the vertex \( T \), where

\[
\phi(C_{m}^{(m,1-m)}) = -\frac{1}{2} + \frac{3}{2} \begin{cases} 
0; & \text{if } 0 \leq m \leq \frac{1}{4}, \\
(4m - 1)^2; & \text{if } \frac{1}{4} \leq m \leq \frac{1}{3}, \\
24m^2 - 12m + 1; & \text{if } \frac{1}{3} \leq m \leq \frac{1}{2}.
\end{cases}
\]

(b): Notice that \( Q(M, C_{c}^{(a,b)}) = Q(C_{c}^{(a,b)}, C_{c}^{(a,b)}) \), so \( \phi(C_{m}^{(a,b)}) = \frac{1}{2} \left( 3\tau(C_{m}^{(a,b)}) - 1 \right) \). Thus \( \phi(C_{m}^{(a,b)}) \) takes its maximal value at the same points as \( \tau(C_{m}^{(a,b)}) \), i.e. the line segment \( RS \), in particular at \( (2m, m) \), where \( \phi(C_{m}^{(m,2m)}) = 1 - 12m^2 \).

There is an intuition lying behind our computations for the case \( C_{c}^{(a,b)} \) to follow. Our copula is basically \( W \) with a bump. Since \( Q(M, C_{c}^{(a,b)}) = Q(C_{c}^{(a,b)}, M) \), we need to minimize the integral of \( C_{c}^{(a,b)} \) over the main diagonal. So, we need to push the bump as far towards northwest as possible.

The main theorem and its corollary now follow. Figure 8 shows the relations between Spearman’s footrule and asymmetry.

**Theorem 15.** Let \( C \in C \) be any copula with \( \mu_{x}(C) = m \). Then

\[
1 - 12m^2 \geq \phi(C) \geq \begin{cases} 
-\frac{1}{2}; & \text{if } 0 \leq m \leq \frac{1}{4}, \\
24m^2 - 12m + 1; & \text{if } \frac{1}{4} \leq m \leq \frac{1}{3},
\end{cases}
\]

and the bounds are attained. In particular, if copula \( C \) is symmetric, then \( \phi(C) \) can take any value in \( [-\frac{1}{2}, 1] \). If copula \( C \) takes the maximal possible asymmetry \( \mu_{x}(C) = \frac{1}{3} \), then \( \phi(C) = -\frac{1}{3} \).

**Corollary 16.** If \( \phi(C) = \phi \), then

\[
0 \leq \mu_{x}(C) \leq \begin{cases} 
\frac{3 + \sqrt{3 + 6\phi}}{12}; & \text{if } \frac{1}{3} \leq \phi \leq -\frac{1}{3}, \\
\sqrt{1 - \phi}; & \text{if } -\frac{1}{3} \leq \phi \leq 1,
\end{cases}
\]

and the bounds are attained.

### 8. Relations between Gini’s Gamma and Asymmetry

To find the relations between Gini’s gamma and asymmetry, we compute minimum and maximum from [21] for \( \kappa = \gamma \). Recall that

\[
\gamma(C) = Q(M, C) + Q(W, C).
\]

**Lemma 17. (a):** \( \min_{(a,b)\in\Delta_{m}} \gamma(C_{m}^{(a,b)}) = \gamma(C_{m}^{(m,1-m)}) = \begin{cases} 
4m^2 - 1; & \text{if } 0 \leq m \leq \frac{1}{4}, \\
20m^2 - 8m; & \text{if } \frac{1}{4} \leq m \leq \frac{1}{3}.
\end{cases} \)
Relations between Spearman’s footrule and asymmetry

(b): For \( (a, b) \in \Delta_m \) in the expression for \( Q(W; C_m^{b,a}) \) four out of nine cases are possible, namely, the first, the second, the fourth, and the fifth. In the third case, when the vertex \( T' \) of
the hexagon is below the counter-diagonal and $R'$ is above it (see Figure 9), the central point $(b, a)$ is above the main diagonal, so $b \leq a$. In the remaining four cases we have the central point above the counter-diagonal. Since in the triangle $\Delta_m$, we have $d_2 = a - m$, Proposition 5 implies that the expression for $Q(W; \overline{C}_m^{(a,b)})$ simplifies to

$$Q(W; \overline{C}_m^{(a,b)}) = \begin{cases} 
0; & \text{if } b \leq \frac{1}{2} - m, \\
-(2b + 2m - 1)^2; & \text{if } \frac{1}{2} - m \leq b \leq \frac{1}{2} - \frac{1}{2}m, \\
-m(4b + 3m - 2); & \text{if } \frac{1}{2} - \frac{1}{2}m \leq b \leq 1 - a - m, \\
(a - 1)^2 + (b - 1)^2 + 2(a - m)(b + m) - 1; & \text{if } 1 - a - m \leq b.
\end{cases}$$

Since $Q(M; \overline{C}_m^{(a,b)}) = 1 - 4m(b - a + m)$ we have

$$\gamma(\overline{C}_m^{(a,b)}) = 1 - 4m(b - a + m) + Q(W; \overline{C}_m^{(a,b)}).$$

For fixed $m$ and $b$ this expression is maximal for $a$ as large as possible, i.e. when the point $(a, b)$ lies on the edge $RU$ or $UT$ (see Figure 5). This means that for $b \leq \frac{1}{2}(m + 1)$ we can take $a = b - m$ and for $b \geq \frac{1}{2}(m + 1)$ we can take $a = 1 - b$. Then we get

$$\gamma(\overline{C}_m^{(a,b)}) = \begin{cases} 
1 - 8m^2; & \text{if } b \leq \frac{1}{2} - m, \\
1 - 8m^2 - (2b + 2m - 1)^2; & \text{if } \frac{1}{2} - m \leq b \leq \frac{1}{2} - \frac{1}{2}m, \\
1 - 8m^2 - m(4b + 3m - 2); & \text{if } \frac{1}{2} - \frac{1}{2}m \leq b \leq \frac{1}{2}, \\
1 - 8m^2 + (2b + m - 1)(2b - 3m - 1); & \text{if } \frac{1}{2} \leq b \leq \frac{1}{2} + \frac{1}{2}m, \\
1 - 6m(2b + m - 1); & \text{if } \frac{1}{2} + \frac{1}{2}m \leq b.
\end{cases}$$

This function is decreasing in $b$, since the first part is constant, the third and the fifth are linear with linear coefficients $-4m$ and $-12m$ respectively, and the second and the fourth are quadratic with derivatives $\frac{d}{db}(1 - 8m^2 - (2b + 2m - 1)^2) = -4(2b + 2m - 1) \leq 0$ and $\frac{d}{db}(1 - 8m^2 + (2b + m - 1)(2b - 3m - 1)) = 4(2b - m - 1) \leq 0$. So, $\gamma(\overline{C}_m^{(a,b)})$ takes its maximal value for $a = m, b = 2m$, i.e. at vertex $R$. Since $m \leq \frac{1}{3}$, the last case in (24) does not occur.
when $b = 2m$. Therefore, we obtain
\[
\gamma(C^{(m,2m)}) = \left\{ \begin{array}{ll}
1 - 8m^2; & \text{if } 0 \leq m \leq \frac{1}{6}, \\
12m - 44m^2; & \text{if } \frac{1}{6} \leq m \leq \frac{1}{5}, \\
1 + 2m - 19m^2; & \text{if } \frac{1}{5} \leq m \leq \frac{1}{4}, \\
2 - 6m - 3m^2; & \text{if } \frac{1}{4} \leq m \leq \frac{1}{3}.
\end{array} \right.
\]

The main theorem and its corollary now follow. Figure 10 shows the relations between Gini’s gamma and asymmetry.

**Theorem 18.** Let $C \in \mathcal{C}$ be any copula with $\mu_{\mathcal{C}}(C) = b$. Then $\gamma(C) \in [g(m), h(m)]$, where
\[
g(m) = \left\{ \begin{array}{ll}
4m^2 - 1; & \text{if } 0 \leq m \leq \frac{1}{3}, \\
20m^2 - 8m; & \text{if } \frac{1}{3} \leq m \leq \frac{1}{2},
\end{array} \right.
\]
and
\[
h(m) = \left\{ \begin{array}{ll}
1 - 8m^2; & \text{if } 0 \leq m \leq \frac{1}{6}, \\
12m - 44m^2; & \text{if } \frac{1}{6} \leq m \leq \frac{1}{5}, \\
1 + 2m - 19m^2; & \text{if } \frac{1}{5} \leq m \leq \frac{1}{4}, \\
2 - 6m - 3m^2; & \text{if } \frac{1}{4} \leq m \leq \frac{1}{3},
\end{array} \right.
\]
and the bounds are attained. In particular, if copula $C$ is symmetric, then $\gamma(C)$ can take any value in $[-1, 1]$. If copula $C$ takes the maximal possible asymmetry $\mu_{\mathcal{C}}(C) = \frac{1}{3}$, then $\gamma(C) \in [-\frac{4}{9}, -\frac{1}{3}]$.

**Corollary 19.** If $\gamma(C) = \gamma$, then
\[
0 \leq \mu_{\mathcal{C}}(C) \leq \left\{ \begin{array}{ll}
\frac{\sqrt{\gamma + 1}}{2}; & \text{if } -1 \leq \gamma \leq -\frac{3}{4}, \\
\frac{\sqrt{5\gamma + 4} + 2}{10}; & \text{if } -\frac{3}{4} \leq \gamma \leq -\frac{4}{9}, \\
\frac{1}{3}; & \text{if } -\frac{4}{9} \leq \gamma \leq -\frac{1}{3}, \\
\frac{\sqrt{15 - 3\gamma} - 3}{3}; & \text{if } -\frac{1}{3} \leq \gamma \leq \frac{5}{16}, \\
\frac{\sqrt{20 - 19\gamma} + 1}{19}; & \text{if } \frac{5}{16} \leq \gamma \leq \frac{16}{25}, \\
\frac{\sqrt{9 - 17\gamma} + 3}{22}; & \text{if } \frac{16}{25} \leq \gamma \leq \frac{7}{9}, \\
\frac{\sqrt{2 - 2\gamma}}{4}; & \text{if } \frac{7}{9} \leq \gamma \leq 1.
\end{array} \right.
\]
and the bounds are attained.
9. Relations between Blomqvist’s Beta and Asymmetry

Blomqvist’s beta $\beta(C)$ of copula $C$ is defined in terms of $C\left(\frac{1}{2}, \frac{1}{2}\right)$ (see [18]). Observe that for $a \leq b$

$$C_c^{(a,b)}\left(\frac{1}{2}, \frac{1}{2}\right) = \begin{cases} 
  c; & a, b \leq \frac{1}{2} \text{ or } \frac{1}{2} \leq a, b \\
  c + a - \frac{1}{2}; & a \leq \frac{1}{2}, \frac{1}{2} \leq b, a + b \geq 1, c + a \geq \frac{1}{2}, \\
  c - b + \frac{1}{2}; & a \leq \frac{1}{2}, \frac{1}{2} \leq b, a + b \leq 1, c - b \geq \frac{1}{2}, \\
  0; & \text{otherwise.}
\end{cases}$$

Then it is straightforward to observe that

$$\min_{(a,b) \in \Delta_{RST}} \beta(C_c^{(a,b)}) = \beta(C_m^{(m,1-m)}) = \begin{cases} 
  -1, & 0 \leq m \leq \frac{1}{4}, \\
  8m - 3, & \frac{1}{4} \leq m \leq \frac{1}{3}.
\end{cases}$$

This gives the lower bound of $\beta$ for all copulas with asymmetry $m$. It is attained at vertex $T$. Intuitively, to minimize $\beta$, the bump of $C_c^{(a,b)}$ needs to be as far away from the point $\left(\frac{1}{2}, \frac{1}{2}\right)$ as possible.

Let us now consider the upper bound. For $a \leq b$ we have

$$C_c^{(a,b)}\left(\frac{1}{2}, \frac{1}{2}\right) = \begin{cases} 
  a - c; & a - c \leq \frac{1}{2} \leq a, \\
  \frac{1}{2} - c; & a \leq \frac{1}{2} \leq b, \\
  1 - b - c; & b \leq \frac{1}{2} \leq b + c, \\
  \frac{1}{2}; & \text{otherwise.}
\end{cases}$$
Then it is straightforward to observe that

$$\max_{(a,b)\in \Delta_{RST}} \beta(C_m^{(a,b)}) = \beta(C_m^{(m,2m)}) = \begin{cases} 
1, & 0 \leq m \leq \frac{1}{6}, \\
3 - 12m, & \frac{1}{6} \leq m \leq \frac{1}{4}, \\
1 - 4m, & \frac{1}{4} \leq m \leq \frac{1}{3}.
\end{cases}$$

The upper bound is attained at vertex $R$.

We have proved the following theorem and its corollary. Figure 11 shows the relations between Blomqvist’s beta and asymmetry.

**Theorem 20.** Let $C \in \mathcal{C}$ be any copula with $\mu_x(C) = m$. Then $\beta(C) \in [g(m), h(m)]$, where

$$g(m) = \begin{cases} 
-1, & 0 \leq m \leq \frac{1}{3}, \\
8m - 3, & \frac{1}{3} \leq m \leq \frac{1}{3}.
\end{cases}$$

and

$$h(m) = \begin{cases} 
1, & 0 \leq m \leq \frac{1}{6}, \\
3 - 12m, & \frac{1}{6} \leq m \leq \frac{1}{4}, \\
1 - 4m, & \frac{1}{4} \leq m \leq \frac{1}{3}.
\end{cases}$$

and the bounds are attained. In particular, if copula $C$ is symmetric, then $\beta(C)$ can take any value in $[-1, 1]$. If copula $C$ takes the maximal possible asymmetry $\mu_x(C) = \frac{1}{4}$, then $\beta(C) = -\frac{1}{3}$.

**Figure 11.** Relations between Blomqvist’s beta and asymmetry
Corollary 21. If $\beta(C) = \beta$, then

$$0 \leq \mu_x(C) \leq \begin{cases} \frac{3 + \beta}{8}; & \text{if } -1 \leq \beta \leq -\frac{1}{3}, \\ \frac{1 - \beta}{4}; & \text{if } -\frac{1}{3} \leq \beta \leq 0, \\ \frac{3 - \beta}{12}; & \text{if } 0 \leq \beta \leq 1. \end{cases}$$

and the bounds are attained.

10. Conclusion

Here is a somewhat surprising fact that emerges from our main results.

Corollary 22. Let $m \in [0, \frac{1}{3}]$. For any measure of concordance $\kappa$ from the set $\{\rho, \tau, \phi, \gamma, \beta\}$ the maximal value of $\kappa(C_{m}^{a,b})$ over the triangle $\Delta_m$ is attained at the same point, namely $R(m, 2m)$.

For any measure of concordance $\kappa$ from the set $\{\rho, \tau, \phi, \gamma, \beta\}$ the minimal value of $\kappa(C_{m}^{a,b})$ over the triangle $\Delta_m$ is attained at the same point, namely $T(m, 1 - m)$.

Furthermore, the following table summarizes the minimizing and maximizing line segments (or points) in the triangle RUT (see Figure 5):

|        | $\rho$ | $\tau$ | $\phi$ | $\gamma$ | $\beta$ |
|--------|--------|--------|--------|----------|--------|
| min    | UT     | UT     | T      | T        | T      |
| max    | RU     | RU     | RU     | R        | R      |

Observe that the minimizing and maximizing segments in the above table are reflected about the line $b = \frac{m+1}{2}$, the symmetry line of the $\Delta_m$ triangle.

We also want to point out another fact for measures of concordance from the set $\{\rho, \phi, \gamma, \beta\}$: A high value of asymmetry, i.e., a value of $\mu_x(C)$ from an interval $(\delta_\kappa, \frac{1}{3})$, implies negative value of $\kappa(C)$ for $\kappa$ in this set. Here $\delta_\kappa \geq \frac{1}{4}$ is a number depending on $\kappa$. In short, high asymmetry implies negative measure of concordance for all measures of concordance we consider except for Kendall’s tau. However, it is not surprising that Kendall’s tau behaves differently compared to the other measures of concordance. Namely, $\rho, \phi, \gamma$ and $\beta$ are linear with respect to convex combinations, while $\tau$ is quadratic [11].

This paper presents the relations between asymmetry and measures of concordance which are nicely seen on our Figures 6, 7, 8, 10, and 11. This study may serve as an encouragement to apply the method proposed here also to investigate other relations between these and other properties and measures of dependence structure of copulas in order to help practitioners to choose their copula models in accordance with their data.

Acknowledgement. The authors are thankful to Fabrizio Durante for proposing the study of relation between concordance and asymmetry. Our special thanks are due to the referees. The suggestions of one of them helped us to greatly improve the paper. The figures in the paper were drawn using the Mathematica software [37].
