Method

**General.** All reactions were performed under an atmosphere of nitrogen by using standard Schlenk or dry box techniques; solvents were dried over Na metal, K metal or CaH₂. ¹H, ¹¹B, ¹³C and ¹⁹F spectra were obtained with BRUKER AVANCE III HD 500MHz spectrometer at 298 K. NMR multiplicities are abbreviated as follows: s = singlet, d = doublet, t = triplet, m = multiplet, br = broad signal. Coupling constants $J$ are given in Hz. UV-vis spectra were measured on a SHIMADZU UV-1900 spectrometer. Electrospray ionization (ESI) mass spectra were obtained at the Agilent Q-TOF6510 Mass Spectrometer. Melting points were measured on a X4 Melting Point apparatus (Beijing Tech, CN) in sealed capillaries and are uncorrected.

DppI,S₁ Mes*BBr₂,S₂ DmpBBBr₂,S₃ 1,2-bis(trimethylsilyl)-hydrazine,S₄ 1,3-diisopropyl-4,5-dimethylimidazol-2-ylidene (IPr₂Me₂),S₅ and 1,3-di-tert-butylimidazol-2-ylidene (tBu)S₆ were synthesized according to literature procedures.

**DppBBr₂:** 5.981 g (16.8 mmol) DppI were dissolved in toluene (60 mL) and 7.40 mL of a 2.5 M solution (18.5 mmol) of n-butyllithium were added. The mixture turned to yellow and was stirred overnight at room temperature. 2.23 mL (23.6 mmol) of BBr₃ was injected and the mixture was stirred for another 12 h. After filtration at 50 °C, the filtrate was concentrated under reduced pressure until incipient crystallization was observed and then stored at −20 °C overnight. The mother liquor was removed and DppBBr₂ was obtained in form of yellow crystals (2.434 g, 36 % yield).

Crystallographic details

All crystallographic intensity data was collected using a Rigaku Oxford Diffraction XtaLAB Synergy-S diffractometer equipped with a HyPix-6000HE Hybrid Photon Counting (HPC) detector, and PhotonJet-S microfocus sealed tube X-ray sources for generating Mo Kα radiation (λ = 0.71 Å, for 3) and Cu Kα radiation (λ = 1.54184 Å, for the others). A suitable single crystal identified by microscopy was mounted on a Nylon loop with paratone oil, and then quickly placed onto the instrument. The crystal temperature was held at 173 K using an Oxford Cryosystems CryostreamPlus 800 open-flow N₂ cryostat. Reflections were recorded, indexed and corrected for absorption with the CrysAlispro software suit. All structures were solved by intrinsic phasing (ShelXT-2015) and refined to convergence by full-matrix least squares methods based on F² (SHELX-2014/2018) embedded in the Olex2. All non-hydrogen atoms were refined with anisotropic displacement parameters (ADPs). Hydrogen atoms attached to carbon (CH) were placed in calculated positions and included using riding model with isotropic thermal parameters, Uiso = 1.2 Ueq (C) for aromatic hydrogen and Uiso = 1.5 Ueq (C) for methyl hydrogen. Hydrogen atoms bonded to nitrogen (NH) were located in geometrically idealized positions and then fixed with d(N-H) = 0.90 Å and Uiso(H) = 1.2 Ueq (N). Due to non-ideal solvent masking, beam stop clipping and the minor presence of diffuse scattering, OMIT instruction was applied during structure refinement. In the crystal structure of 3, one phenyl ring was found to be disordered. Based on the residual electron density located in this region, the disorder was successfully divided into two components (C31A-C36A, and C31B-C36B) using PART command, and a free variable was introduced for the occupancy refinements.
The occupancies of both components were constrained to sum to 1.0. In order to get reasonable geometry and ADPs for the disorder atoms, some structural and thermal parameter restraints (SADI, SIMU and ISOR) were adopted in the refinements. In the unit cell of compound 5, there exists a large region of disordered solvent molecules, which could not be modeled as discrete atomic sites. PLATON/SQUEEZE\textsuperscript{12} was used to calculate the diffraction contribution of the solvent molecules to produce a set of solvent-free diffraction intensities. The SQUEEZE calculations showed a total solvent accessible area volume of 1013 Å\textsuperscript{3} and the residual electron density amounted to 258 electron per unit cell, corresponding to nearly 5 molecules of n-hexane (about 0.55 n-hexane molecules per asymmetric unit). For comparison, the residual factors (R\textsubscript{1}/wR\textsubscript{2}) were 0.0677/0.2147 for the best disorder model, and 0.0559/0.1691 for the model squeezed, respectively. Details of the SQUEEZE calculations are included in its CIF file. Additionally, two tertiary butyl groups and one bromine atom were disordered, which were resolved with PART command and some restraints in geometry (DFIX and SADI) and thermal parameters (SIMU and ISOR) in the refinement. In cases of 6 and 7, tertiary butyl groups were also disordered over two positions similar to the disorder model for 5. These groups was treated analogously to that of 5. In 6, toluene is disordered and PART instruction was applied for solving this problem. Furthermore, the molecule, 7, is fully disordered over two conformations across an inversion center, which give rise to the heavy disorder of the bicyclic moiety. PART -1 instruction was used to solve this problem. Restraints including ISOR and SIMU on displacement parameters were applied. The refinement results are summarized in Table S1.

Computational details

Geometry optimizations were carried out with the Gaussian 09 package$^{513}$ with the M06-2X functional.$^{514}$ The Def2-SVP basis set was used for all the atoms. Frequency calculations at the same level of theory were performed to identify the number of imaginary frequencies (zero for local minimum and one for transition states) and provide the thermal corrections of Gibbs free energy. Transition states were submitted to intrinsic reaction coordinate (IRC) calculations to determine two corresponding minima.

The single-point energy calculations were performed at the M06-2X/Def2-TZVP level of theory for solution-phase (benzene). The gas-phase geometry was used for all the solution phase calculations. The SMD method was used with the corresponding solvent, while Bondi radii$^{515}$ were chosen as the atomic radii to define the molecular cavity. The correction of Gibbs free energy from frequency calculations was added to the single-point energy to obtain the Gibbs free energy in solution. All the energies reported in the paper correspond to the reference state of 1 mol/L, 298K. Natural bond orbital (NBO) calculations were carried out using NBO 6.0 program$^{516}$ at the M06-2X/TZVP level of theory. Intrinsic bond orbitals (IBOs) were carried out using ORCA program$^{517}$ at the PBE/Def2-TZVP//M06-2X/Def2-SVP level of theory. The IEFPCM solvation model with n-hexane was used for these TD-DFT calculations.
