Abstract

An analytical methodology has been developed and validated with the purpose to identify and quantify four parabens (methylparaben, ethylparaben, propylparaben and n-butylparaben) in water samples. The combination of rotating disk sorptive extraction (RDSE) technology with ultra-high performance liquid chromatography (UHPLC), along with electrospray ionization source (ESI) and time of flight mass spectrometry (TOF/MS) in trap mode, allowed avoiding derivatization processes and a reduction of the chromatographic time required, achieving a greener analytical method. In this method, detection limits and precision (%RSD) were lower than 0.018 µg L\(^{-1}\) and lower than 9.7% for all the parabens, respectively, being better than similar works. Matrix effect and absolute recoveries were studied in tap and sewage water samples, observing suppressions of the signals for all analytes, and absolute recoveries around 60%. This methodology was applied to the analysis of two sewage samples (punctual and composite) located in Santiago, Chile.

**Keywords:** Rotating-disk sorptive extraction (RDSE), parabens, UHPLC-ESI-TOF/MS, matrix effect, water samples.
Introduction

Parabens is the name given to a group of \( p \)-hydroxybenzoic acid (PHBA) esters that include methylparaben (MP), ethylparaben (EP), propylparaben (PP) and \( n \)-butylparaben (BP), among others. They are considered ideal preservatives because of their wide spectrum of anti-microbial activity, preventing the product from microorganisms, fungi or bacteria\(^1\). Besides, they are highly stable in regard to variation in pH, relatively safe to use, and have low production costs. Owing to these characteristics, they have been incorporated in products of daily use such as cosmetics, pharmaceutical drugs and foods\(^2-4\).

Parabens are found in a large variety of products in low concentrations at which the population and the environment are exposed. Recent studies have shown that parabens produce reproductive disorders in animal and human models\(^5\). In 2004, Darbre et al. found the presence of parabens in human breast tumor tissue at a concentration of between 4-20 ng g\(^{-1}\)\(^6\) and, thus, it is speculated that they may influence the growth and development of tumors\(^7,8\). Regarding environmental issues, many personal care chemicals are continuously released in the aquatic media through domestic sewage; therefore, a growing concern has arisen in relation to their potential long term effects on wildlife\(^1,8-10\).

According to the literature, several analytical methods have been proposed to detect parabens contributing to more efficient and greener technologies\(^11\). Extraction and desorption process are habitually considered the most crucial steps in analytical methods, evidencing the impact on results accuracy. For that reason, the extraction and desorption of parabens from aqueous samples were chemometrically optimized in a previous study developed by Becerra-Herrera et al.\(^12\) by using rotating disk sorptive extraction (RDSE) technique. After that, another study was developed using RDSE and cork as a sorbent phase, making a greener method\(^13\).

Liquid chromatography combined with mass spectrometry (LC-MS) has become one of the most extensively used techniques for the determination of parabens in aqueous matrices, due to
its high sensitivity and specificity\textsuperscript{14}. Currently, Ultra High Performance Liquid Chromatography (UHPLC) is becoming more commonly used and in combination with electrospray ionization source (ESI) and mass spectrometry (MS), they both can provide a significant increment in the method sensitivity and feasibility, as well as a reduction of the analysis time\textsuperscript{15,16}. There are different mass analyzers; being triple quadrupole (MS/MS), time of flight (TOF) and Orbitrap the most frequently used\textsuperscript{17-19}. This last one allows the obtaining of a full-scan product ion spectra with accurate masses of fragment ions, providing structural information of the compound. The identified compound structure is confirmed by comparing changes between experimental masses of fragment ions which origin from parent ions, and exact molecular masses\textsuperscript{20}.

The aim of this study is to develop a chromatographic method for UHPLC-ESI-TOF/MS that permits identifying and quantifying 4 parabens: MP, EP, PP and BP in aqueous samples. The research includes the study of mobile phases using different solvents, mobile phase flows, injection volumes, injection mode, and ESI in positive and negative ion mode. The ion suppression/enhancement effect was studied and the different responses of each compound to this matrix effect were discussed. The eco-efficiency of the method proposed was calculated and compared with others, demonstrating that it is the greenest method, and being consider an excellent green analytical chemistry method. Lastly, this method was applied to analyze sewage samples from two locations of Santiago, Chile, in order to identify and quantify the parabens in real samples.

**Experimental**

**Reagents and chemicals**

Water from a Millipore Milli-Q Plus water system (Billerica, MA) was used throughout the
experiment. Methyl paraben, ethyl paraben, propyl paraben, and $n$-butyl paraben were purchased from Sigma-Aldrich (Milwaukee, WI, USA). The standard stock solution of each analyte (200 mg L$^{-1}$) was prepared separately in methanol (MeOH) (Fisher Scientific, Fair Lawn, NJ, USA). Nitrogen with a purity of ≥ 99.999% was purchased from Linde (Santiago, Chile) and it was used in the final extract evaporation. Methanol (LC/MS grade, 99.8% purity), Acetonitrile (ACN) (LC/MS grade, 99.8% purity), and Ammonium acetate were supplied by Merck. The Oasis® HLB extraction cartridges were obtained from Waters Corporation (Milford, MA, USA).

Sample preparation

An extraction method (RDSE) specifically designed for parabens extraction from wastewater samples was used$^{12}$. In this process, Oasis® HLB sorbent (50 mg) was loaded on the disk cavity. Before extraction, the disk containing the sorptive phase was placed inside the beaker and conditioned with ethyl acetate, methanol and Milli-Q water stirring at 2000 rpm for five minutes each$^{12}$. For extraction, 20 mL of a sample at pH 6 (buffered with HCl 1M) with 5% methanol were added to the beaker and the disk was rotated at 2900 rpm for 70 minutes at room temperature. These conditions were previously optimized by Becerra-Herrera et al.$^{12}$. The effects of pH value and % methanol on the extraction of parabens were studied: pH values and % methanol ranging from 2 to 10, and 0 to 15%, respectively were checked; showing the best areas using pH 6 and 5% methanol. After extraction, the disk was placed into a 15 mL beaker containing 5 mL of methanol as a desorption solvent and stirred twice for 10 minutes at 2000 rpm. Afterwards, the methanol extract containing the concentrated analyte was evaporated under a N$_2$ stream to dryness$^{12}$. At the end, the extract was redissolved in 500 μL of methanol and it was filtered through a 0.22 μm pore size and 13 mm diameter nylon filter. Ten microliters of this solution
were injected in the UHPLC−ESI−TOF/MS.

In the samples study, 60 mL of water sample were necessary to perform the analysis in triplicate (20 mL × 3).

**UHPLC−ESI−TOF/MS analysis**

A PerkinElmer Flexar FX-15 ultra-performance liquid chromatography system (PerkinElmer, USA) with a binary pump system, a vacuum degasser, a cooling autosampler, and a thermostated column compartment was used to perform chromatographic analysis. Separation was carried out using an analytical column Brownlee SPP−C18 (2.1 mm × 75 mm, 2.7 µm) (PerkinElmer, USA) which was kept at 20ºC. Moreover, optimum separation was achieved thanks to a binary mobile phase gradient at a flow rate of 0.3 mL min⁻¹, and the injection volume was 10 µL. Solvents were (A) water/ammonium acetate (5 mM) pH 6.5, and (B) methanol. In this sense, the program used 1.5 min to equilibrate the system prior to injecting the sample (0% B). After that, the gradient elution program was as follows: 0-1 min, 0-90% B; 1-2 min, 90-95% B; 2-3 min, 95-100% B; 3-4 min, 100% B.

The identification and quantification of parabens were both obtained using an AxION 2 TOF MS system equipped with a Dual Probe Electrospray Ionization Source (ESI) and controlled by Chromera Software and TOF MS Driver Software (PerkinElmer, USA). During this process, the source working conditions were: capillary exit -100 V, capillary voltage 6000 V, gas flow rate 10 L min⁻¹, drying gas temperature 300 ºC and nebulizer pressure 80 psi. Acquisition function was in Trap mode, setting the parameters “IG Exit Low” and “Trap/Pulse Delay” at 6 and 19 µs, respectively so as to improve the sensibility of the analysis. LC/MS accurate mass spectra were recorded across the range 100–1200 m/z in negative mode. The identification and quantification of the four parabens was performed using commercial standards indicated above.
Results and Discussion

Method optimization to determine parabens

In order to perform an optimal extraction of parabens from water, different chemical and pre-concentration factors were examined. Variables were studied in tap water spiked with a known concentration of parabens to evaluate matrix effect, among others. Taking into account that the TOF analyzer is combining with an Electrospray ionization source, the ionization of analytes should be assisted by using an appropriate mobile phase to achieve the efficient deprotonation and separation of the parabens. At this point, it is pertinent to work within a range of pH 2 to 9 since the best column stability is located between these values.

Bearing this information in mind, different mobile phases (methanol, acetonitrile, water mixed with formic acid, acetic acid and ammonium acetate) in gradient programs were tested. Figure 1 shows the amplitudes achieved when different mobile phases were studied. As can be seen, pH values were from 2.3 to 6.5. Working with pH 6.5, 5 mM of ammonium acetate were added to aqueous phase, stabilizing the pH water and obtaining better results. Higher pH values were not analyzed as the use of higher salt concentration is not recommended for the column stability and lifetime. Comparing the organic modifier, amplitudes obtained using acetonitrile were lower than using methanol. Suitably, methanol was selected as organic modifier. It is pertinent to highlight that stability in retention times was also better using mobile phases containing methanol, as well as the higher peak area and peak shape of the analyzed compounds.

In order to optimize the identification and quantification of parabens in standard solutions and sewage samples; mobile phase flows (0.2, 0.3, 0.4 and 0.5 mL min⁻¹), two injection volumes (5 and 10 μL) and three injection mode (partial loop, fixed loop and μL-pick up) were tested. The combination of 0.3 mL min⁻¹ flow rate, 10 μL injection volume, and partial loop injection showed optimal compounds separation within 4 minutes (Fig. 2). ESI in positive and negative
ion mode was also evaluated, observing that all compounds were ionized in negative mode. **Knowing the advantages in the use of trap mode**\(^{21}\), detection was monitored using this option.

Table 1 shows the empirical formula, exact mass, theoretical and experimental \(m/z\) in negative mode, error (ppm) and retention time (min) for each compound. As evidenced, ppm error was smaller than 1.2 for all the studied compounds, proving the TOF/MS reliability.

It is remarkable the use of the Dual Probe Electrospray Ionization Source, as it presents a great improvement over conventional Electrospray Ionization Sources letting both calibration and sample analysis simultaneously. Thus, the mass precision is guaranteed, reducing the error (ppm).

As detailed in Table 1, all parabens have different \(m/z\) value, supporting their determination by liquid chromatography in similar times even at the same time. Additionally to the UHPLC, the AxION 2 TOF MS system has a connected syringe pump, whereby the sample may be directly infusioned into the ESI-TOF MS without using the UHPLC. **In Figure 3, a mass spectrum of 4 parabens obtained using syringe pump is shown.** The use of this syringe pump allows identifying the existence of parabens in samples in 10 seconds. Due to the mechanism of the syringe pump, it is impossible to perform a calibration curve which would allow quantify parabens, however, a preliminary screening of the parabens presence in a sample could be performed. Furthermore, thanks to the use of a TOF MS analyzer, the stability of \(m/z\), the ppm error, and the isotopy of each compound could be checked ensuring the determination of each compound and eliminating possible interferences. It is remarkable that, avoiding the HPLC use, some sample pretreatment steps can be omitted, reducing reagents and time, and allowing performing a screening of different kinds of liquid samples (urine, milk, juice, etc.).

*Calibration curve, LOD and LOQ, and method precision*

With the purpose to assure both a suitable identification and a quantification of the studied
compounds, the figures of merit of the chromatographic method were studied. The calibration curves, correlation coefficients, detection limits (LODs) and quantification limits (LOQs) were obtained by LC–TOF/MS analysis with an extracted ion chromatogram (EIC) mode of deprotonated molecular ion. Linearity was scrutinized by the injection of standard solutions at eight concentration levels from 10 to 500 µg L$^{-1}$. Coefficients of correlation ($r^2$), method precision, LODs and LOQs have been detailed in table 2.

The precision of this method, expressed in terms of relative standard deviation (%RSD), was evaluated for each compound performing the whole procedure (extraction process and determination of compounds in UHPLC–ESI–TOF MS) 10 times with parabens at concentration levels of 250 µg L$^{-1}$ in sewage. Repeatability values lower than 9.7% were achieved for all compounds (Table 2).

The LODs and LOQs of the method were determined by injecting a calibration curve in matrix (sewage) between 5 and 50 µg L$^{-1}$. Resulting in values ranging from 0.008 to 0.018 and 0.027 to 0.055 µg L$^{-1}$, respectively.

To study matrix effect (ME) and recovery (Re), a technique previously defined was developed to evaluate these processes independently$^{21}$. Thus, making use of the equations 1 and 2 for matrix effect and recovery, respectively, precise values were acquired in tap water and sewage:

\[
\text{ME (\%)} = 100 \times \frac{(\text{Ax}_s2 - \text{Ax}_s3)}{\text{Ax}_s1} \quad (\text{eq. 1})
\]

\[
\text{Re (\%)} = 100 \times \frac{(\text{Ax}_s4 - \text{Ax}_s3)}{\text{Ax}_s2} \quad (\text{eq. 2})
\]

where Ax$_s1$, Ax$_s2$, Ax$_s3$ and Ax$_s4$ correspond to the abundances (A) obtained for the parabens ($x$) from samples S1 (multi-standard solution of 500 µg L$^{-1}$ of each paraben); S2 (tap water/sewage extract obtained using RDSE that had been enriched with 500 µg L$^{-1}$ of the parabens before injection); S3 (extract obtained directly from a tap water/sewage sample); and S4 (extract obtained from a tap water/sewage sample enriched with 12.5 µg L$^{-1}$ of each paraben).

On the one hand, as Table 2 shows, all compounds had a ME value lower 100, meaning that all
compounds had experienced suppression in these responses, showing similar values in tap water and sewage. On the other hand, absolute recovery values were different in tap water and sewage, being better values when tap water was tested.

**Real sample analysis**

In order to assess the efficiency of the proposed method, it was applied to the analysis of sewages of different places of Santiago, Chile. In each location, a punctual (P) sample (collected by a specialist between 10:00 and 11:00 am) and a composite (C) sample (collected for 24 hours) were taken. All samples were prepared in triplicate and injected three times into UHPLC-ESI-TOF MS.

As shown in table 3, methylparaben and \(n\)-butylparaben were found in all punctual and composite samples, being lower in composite samples. Propylparaben showed the highest concentrations in the first place, being similar in punctual and composite samples. As an example, an extracted ion chromatogram of parabens in a punctual sewage sample (S-1P) is showed in figure 4. This information might indicate that the concentrations obtained in composite samples are lower due to the dilution of the sample (collected for 24 hours).

**Eco-efficiency and comparison with previous methodologies**

Considering the analytical eco-scale proposed by Galuszka et al. in 2012\(^{26}\), which is based on the assignment of penalty points to the parameters of an analytical process; this parameter joined to recoveries, LOD, and %RSD of this work and similar previous works reported in the literature were compared in table 4. According to this scale, an ideal green analysis has a value of 100 points. For each parameter of the analytical procedure (quantity of reagent, hazard, energy and waste), penalty points are assigned, allowing to classify the methodology within green chemistry.
Penalty points have a value of 3 for the methodology developed combining RDSE and HPLC-TOF/MS, which means that the analytical scale has a value of 97, positioning it as an excellent green methodology. As detailed in table 4, the eco-efficiency (EE) of this work compared with other methodologies is excellent, mainly due to the low volume of solvents used and the reduction in the chromatographic time. It is noteworthy that chromatographic time was lower than in the reported studied, and it was reduced three times in comparison to the method proposed by the authors\textsuperscript{12}. In addition, LOD and %RSD were also better in this study. Comparing the proposed method with other previously reported using RDSE with green sorbents and HPLC-MS/MS\textsuperscript{12}, the EE is similar but this method obtained a better LOD and chromatographic time. A combination between both methods (one for extraction method and the other for analysis method) would be an excellent green method. Recoveries were lower than in other studies but it only represent the extraction method, which was the same previously developed by Becerra-Herrera el at.\textsuperscript{12}. The lower values in this study can be a result of matrix effect when UHPLC-TOF/MS was used to determine parabens, not studied previously for these compounds in any reported work.

Conclusions

A rapid and green methodology for the identification and quantification of parabens in water samples has been purposed.

The RSDE method combined with an UHPLC-ESI-TOF/MS showed fruitful results in RSD%, ppm error, matrix effect, recovery and LOD; with the concomitant reduction in analysis time, as well as the avoided derivatization process. The designed method grants a reliable identification and quantification of four parabens in only 4 minutes.

To validate the methodology, these compounds were determined in punctual and composite
sewage samples. This platform can be used to perform a screening of parabens in samples in 10 seconds by direct infusion.

| RDSE – HPLC/MS    | 8                 | 0.24–1.81 µg L⁻¹ | 80–115  | 4.7–16 | 97  | 13   |
| RDSE – UHPLC-TOF/MS | 4 / 0.2*          | 0.008–0.018 µg L⁻¹ | 59.8–67.1 | 2.5–9.7 | 97  | This work |

LLE: liquid–liquid extraction; SM-SLLME: stir-membrane solid–liquid–liquid micro-extraction; MLPDE: matrix liquid-phase dispersion extraction; BamuE: bar adsorptive micro-extraction.

*time necessary when direct infusion was employed.
Figure Captions

Fig. 1. Amplitudes achieved when different mobile phases were tested in UHPLC–ESI–TOF MS (FAc: formic acid; AAc: acetic acid; AmA: ammonium acetate). The arrow indicates the pH increment using the different mobile phases.

Fig. 2. Extracted ion chromatograms of parabens in a multi-standard solution containing 500 µg/L of each analyte.

Fig. 3. Mass spectrum of methylparaben (151.0395), ethylparaben (165.0552), propylparaben (179.0703), and n-butylparaben (193.0865) obtained by direct infusion.

Fig. 4. Extracted ion chromatogram of parabens in a punctual sewage sample (S-IP).
