HIGHLIGHTS

- ANGPTL4/8 levels are increased in patients with type 2 diabetes.
- ANGPTL4/8 levels are inversely correlated with HDL in type 2 diabetes patients.
- ANGPTL4 is an inhibitor of endothelial lipase (EL).
- ANGPTL4 inhibits EL more potently than ANGPTL3 inhibits EL.
- ANGPTL4/8 inhibits EL less potently than ANGPTL4 inhibits EL.

ABSTRACT

We previously demonstrated that angiopoietin-like protein 8 (ANGPTL8) forms ANGPTL3/8 and ANGPTL4/8 complexes that increase with feeding to direct fatty acids (FA) toward adipose tissue through differential modulation of lipoprotein lipase (LPL) activity. Each complex correlated inversely with high density lipoprotein cholesterol (HDL) in control subjects. We thus investigated ANGPTL3/8 and ANGPTL4/8 levels in type 2 diabetes patients, who can present with decreased HDL. While ANGPTL3/8 levels in type 2 diabetes patients were similar to those previously observed in normal controls, ANGPTL4/8 levels were roughly twice as high as those in control subjects. Concentrations of ANGPTL3/8 and ANGPTL4/8 in type 2 diabetes patients were inversely correlated with HDL, with the correlation being significant for ANGPTL4/8. We therefore measured the ability of the various ANGPTL proteins and complexes to inhibit endothelial lipase (EL), the enzyme which hydrolyzes phospholipids (PL) in HDL. While confirming ANGPTL3 as an EL inhibitor, we found that ANGPTL4 was a more potent EL inhibitor than ANGPTL3. Interestingly, we observed that while ANGPTL3/8 had increased EL-inhibitory activity compared to ANGPTL3 alone, ANGPTL4/8 exhibited decreased potency in inhibiting EL compared to ANGPTL4 alone. Together, these results show for the first time that ANGPTL4 is a more potent EL inhibitor than ANGPTL3 and suggest a possible reason for why ANGPTL4/8 levels are correlated inversely with HDL.

1. Introduction

Triglyceride (TG) and high-density lipoprotein (HDL) metabolism are intertwined in a complex process that has yet to be completely elucidated. Their levels are often inversely correlated with each other, both during fasting conditions as well as postprandially [1]. Patients with type 2 diabetes in particular often present with increased TG and decreased HDL [2]. The reasons for the decreased HDL levels are not fully known, however, one factor proposed to be involved is cholesteryl ester transfer protein (CETP), which catalyzes the transfer of TG from apolipoprotein B (ApoB)-containing lipoprotein particles to HDL in exchange for the transfer of cholesteryl esters from HDL to ApoB-containing particles [3]. As a result of CETP activity, increases in TG are thought to lead to increased transfer of TG to HDL, resulting in more TG-rich HDL, which undergoes a higher rate of catabolism, thus leading to decreased HDL. Several other factors, however, are clearly important in regulating HDL levels. The enzyme endothelial lipase (EL) is a phospholipase that hydrolyzes phospholipids (PL) in HDL [4]. Decreased EL activity...
occurring with EL gene knockat has been associated with increased
HDL, while increased EL activity is thought to cause decreased HDL due
to the removal of PL from HDL which results in PL-poor HDL particles
that are more readily cleared from the circulation [5, 6]. Similarly,
decreased levels of the EL inhibitor angiopoietin-like protein 3
(ANGPTL3) that occur with ANGPTL3 knockout mutations are associ-
ated with decreased HDL [7]. In addition, administration of a neutral-
izing anti-ANGPTL3 antibody has been reported to cause decreased HDL
[8]. Because ANGPTL3 can form a complex with ANGPTL8 to potent-
ly inhibit lipoprotein lipase (LPL), the enzyme that hydrolyzes TG to
generate fatty acids (FA), decreased HDL is also accompanied by
decreased TG [9, 10]. Thus, ANGPTL3 inhibition provides an example in
which TG and HDL do not move in opposite directions, as both decrease
at the same time.

In a recent study, we examined the mechanisms by which the
atypical ANGPTL protein ANGPTL8 [11, 12, 13, 14] acts to increase
TG. We demonstrated that ANGPTL8 acts as a nutrient sensor to form
complexes with ANGPTL3 and ANGPTL4 to increase and decrease
respectively their LPL-inhibitory activities to direct FA storage in ad-
ipose tissue [15]. ANGPTL3/8 functions primarily in an endocrine
manner by inhibiting LPL in skeletal muscle so that circulating TG that
can be routed to the fat [15, 16]. In the adipose tissue, LPL inhibition is
simultaneously reduced by increased localized ANGPTL8/8 [15].
Interestingly, we found that in control subjects, circulating levels of
ANGPTL3/8 and ANGPTL4/8 increased significantly after feeding and
that levels of both complexes were inversely correlated with HDL
[15].

In light of these findings and because increased TG and decreased
HDL are often seen in type 2 diabetes [2], we investigated circulating
levels of ANGPTL3/8 and ANGPTL4/8 in type 2 diabetes patients. We
found that ANGPTL3/8 and ANGPTL4/8 were both directly correlated
with triglycerides (TG) and inversely correlated with HDL, with the in-
verse HDL correlation being significant for ANGPTL4/8. We therefore
considered whether ANGPTL4 and/or ANGPTL8 might inhibit EL and
measured the ability of each of the respective ANGPTL proteins and
complexes to inhibit EL activity. In so doing, we confirmed that
ANGPTL3 inhibits EL, but also found that ANGPTL4 was a more potent EL
inhibitor than ANGPTL3. Interestingly, we also observed that
ANGPTL4/8 was a much less potent EL inhibitor than ANGPTL4.
Together, these results suggest that as ANGPTL4/8 levels increase there
decreased inhibition of EL, leading to more EL-mediated hydrolysis of
PL in HDL, which in turn leads to decreased HDL. Our data thus show for
the first time that ANGPTL4 is a more potent EL inhibitor than ANGPTL3
and suggest a possible explanation for why ANGPTL8/4 concentrations
correlate inversely with HDL levels.

2. Materials and methods

2.1. Lipid measurements and serum samples from type 2 diabetes patients
and normal subjects

After obtaining proper informed consent for exploratory analyses,
baseline serum samples were collected from 93 patients with type 2
diabetes enrolled in a clinical trial. These samples were drawn under
fasting morning conditions using serum separator tubes and stored at -80°C prior to subsequent analyses. Serum samples were also obtained from
99 normal subjects for the Eli Lilly Research Blood Donor Program after
the anonymized subjects gave their informed consent for sample collect-
ion. These samples were also drawn under fasting morning conditions
using serum separator tubes and stored at -80°C prior to subsequent analyses. All lipid markers and ApoB were measured using a Roche CobaB
instrument. The ratio of ApoB to low density lipoprotein cholesterol
(LDL-C) was used as a surrogate marker for small dense LDL-C. Non-HDL-
C was calculated by subtracting HDL-C from total cholesterol (TC). Levels
of TG and HDL-C were used to calculate the TG/HDL ratio.

2.2. Recombinant proteins and complexes

Human ANGPTL sequences were ANGPTL8: NP_061157.3, ANGPTL3:
NP_055310.1, and ANGPTL4: NP_647475.1. C-terminal HIS-tagged
ANGPTL4 and ANGPTL3 were produced stably in CHO cells and tran-
siently in HEK293 cells, respectively. Both were purified through nickel-
nitrioltriacetic acid (Ni-NTA) affinity, followed by size exclusion chro-
matography (SEC). ANGPTL3/8 complex was produced in HEK293 cells
through transient co-transfection. Nucleotide sequences encoding mouse
IgG kappa signal peptide-HIS tag-mature human serum albumin (HSA)-
PreScission cleavage site-mature ANGPTL8 were inserted into a mani-
malian expression vector containing a cytomegalovirus (CMV) promoter,
as were the nucleotide sequences encoding C-terminal Flag-
tagged ANGPTL3. Protein expression was performed through transient
co-transfection of both expression constructs in HEK293 cells cultured in
serum-free media. Culture media were harvested 5 days post transfection
and stored at 4°C for subsequent protein purification at 4°C. Four liters
of culture media were supplemented with 1 M Tris-HCl (pH 8.0) and 5 M
NaCl to final concentrations of 25 mM and 150 mM, respectively. The
media were incubated with 150 ml of Ni-NTA resin (Qiagen) overnight.
The resin was then packed into a column and washed with buffer A (50
mM Tris-HCl, pH 8.0, 0.3 M NaCl). Elution was performed with a 0–300
mM imidazole gradient in buffer A. Fractions containing HIS-HSA-
ANGPTL3/8 complexes were pooled, concentrated, loaded onto a
HiLoad Superdex 200 column (GE Healthcare), and eluted with buffer A.
Fractions containing HIS-HSA-ANGPTL8/3 complexes were again
pooled, concentrated, and digested with PreScission protease to remove
HSA from the fusion protein. The PreScission digested protein sample
was loaded onto another HiLoad Superdex 200 column and eluted with
storage buffer (20 mM HEPES pH 8.0, 150 mM NaCl). Fractions con-
taining ANGPTL3/8 were pooled and concentrated.

To ensure purity during the ANGPTL3/8 purification process, the
initial Ni-NTA affinity purification first removed free ANGPTL3. After
SEC, purified HIS-HSA-ANGPTL3/8 complex and free HIS-HSA-
ANGPTL8 were obtained. PreScission digestion (which cleaved be-
tween HSA and ANGPTL8) resulted in ANGPTL3/8 complex, HIS-HSA,
and free ANGPTL8. Free ANGPTL8 was precipitated out, leaving only
ANGPTL3/8 complex and HIS-HSA. ANGPTL3/8 complex and HIS-HSA
were separated with a second SEC step, resulting in highly purified
ANGPTL3/8 complex without HIS-HSA contamination. This ensured that
very pure ANGPTL3/8 complex was produced. The exact same approach
was used for expression and purification of the ANGPTL4/8 complex. All
proteins and complexes were maintained at a <0.01 EU/ug of endotoxin.
Protein concentrations were determined using a bicinchoninic acid
(BCA) assay. One mg of each recombinant ANGPTL protein or complex
was characterized using gradient gel electrophoresis with Bio-Rad
4–20% Mini-Protein Tris-glycine gels, followed by Coomassie Blue
staining to verify the purity of the respective proteins and complexes,
which were all stored at -80°C. For purposes of molar conversions, a
molecular weight of 179 kDa was used for ANGPTL3/8 (3:1 ratio), while
a molecular weight of 64 kDa was used for ANGPTL4/8 (1:1 ratio).

The nucleotide sequence encoding C-terminal HIS-tagged human EL
(NP_006024.1) was inserted into a mammalian expression vector con-
taining a cytomegalovirus (CMV) promoter. EL protein expression was
performed through transient transfection in HEK293 cells cultured in
serum-free media. Culture media were harvested 5 days post transfection
and stored at 4°C for subsequent protein purification. Two liters of
culture media were supplemented with 1 M Tris-HCl (pH 7.5) and 5
M NaCl to final concentrations of 25 mM and 150 mM, respectively. The
media were incubated with 25 ml of HisPur Ni-NTA resin (ThermoFisher)
for 3.5 h. The resin was then packed into a column and washed with
buffer A (50 mM Tris-HCl, pH 7.5, 0.3 M NaCl). Elution was performed
with a 0–300 mM imidazole gradient in buffer A. Fractions containing
EL-His were pooled, concentrated, loaded onto a HiLoad Superdex 200
column (GE Healthcare), and eluted with PBS. The fractions were pooled,
concentrated, aliquoted and stored at -80 °C. The recombinant EL protein concentration was determined using a bicinchoninic acid (BCA) assay.

### 2.3. ANGPTL antibodies and serum assays

An anti-human ANGPTL8 antibody (residues 22–198) was generated using hybridoma techniques by Precision Antibody Sciences. An anti-human ANGPTL4 antibody was generated by immunization with recombinant ANGPTL4 (residues 26–161). An anti-human ANGPTL3 antibody was generated after immunization with recombinant ANGPTL3 (residues 17–220). Clones of interest were screened for non-overlapping epitopes, and antigen-specific variable heavy (VH) and light (VL) gene sequences were determined from extracted RNA using a mouse Ig primer set (EMD Millipore). Variable domains were transferred into separate murine constant region expression vectors for antibody production, transfeeted into CHO cells, and purified using protein A chromatography. Antibodies were biotinylated using a Pierce kit and ruthenium-labeled using a MesoScale Discovery (MSD) kit, with MALDI-TOF performed to verify that appropriate labeling had occurred. Antibodies were diluted in 50% glycerol and stored at -20 °C. Distinguished immunoassays were used to measure ANGPTL3/8 and ANGPTL4/8 complexes in human serum. For the ANGPTL3/8 assay, the capture antibody recognized ANGPTL8, and the detection antibody recognized ANGPTL3. For the ANGPTL4/8 assay, the capture antibody recognized ANGPTL4, and the detection antibody recognized ANGPTL8. For each assay, MesoScale Discovery (MSD) streptavidin plates were washed three times with TBST (Tris buffered saline containing 10 mmol/L Tris, 0.15 mol/L NaCl, and 0.05% Triton X-100, 5 mmol/L EDTA, and 5 mmol/L EGTA). Serum samples were diluted in assay buffer and added to their respective wells for a 2-hour incubation at RT. After aspiration, wells were washed three times, and 50 μL of ruthenium-labeled detection antibody were added for a 1-hour incubation at RT. Following aspiration, wells were washed three times, and 150 μL of MSD read buffer were added. Electrochemiluminescence from electrical excitation of ruthenium in the wells was detected using an MSD plate reader.

### 2.4. Endothelial lipase (EL) cell-based activity assay

The nucleotide sequence encoding human EL (NP_006024.1) was inserted into pLent6.3 vector (Invitrogen) to generate lentivirus, which was used to create an EL-stable expression HEK293T cell line, which was confirmed by qPCR and enzymatic activities. The cell line was grown and maintained in DMEM/F12 (3:1) (Invitrogen), 10% FBS (Hyclone), and 5 μg/ml blasticidin (Invitrogen). Human EL-stable expression cells were seeded at density of 50,000 cells/well in tissue culture-treated poly-styrene 96-well plates (Costar) in growth medium (3:1 DMEM/F12, 10% FBS, and 5 μg/ml blasticidin). After overnight incubation at 37 °C, medium was replaced with 80 μL of medium (OptiMEM, Invitrogen) containing serially diluted ANGPTL proteins or complexes. Cells were incubated for 1 h before adding 20 μL of 5X working solution that was freshly prepared with reaction buffer (50 mM Tris-HCl, 140 mM NaCl, 2 mM CaCl₂) containing the EnzChek phospholipase A₁ (PLA₁) selective substrate PDE-A₁ (N-((6-(2,4-DNP)aminohexanoyl)-1-BODIPYTM-FL-C5)-2-hexyl-sn-glycero-3-phosphoethanolamine) (Invitrogen), DOPC (1,2-dioleoyl-sn-glycero-3-phosphocholine), and DOPG (1,2-dioleoyl-sn-glycero-3-phospho-rac-(1-glycerol) sodium salt) (Sigma) to achieve final concentrations of 1, 10, and 10 μM respectively. The 5X working solution was prepared by mixing one part of 1 mM PDE-A₁, one part of 10 mM DOPC, and one part of 10 mM DOPG and adding the mixture drop by drop into 197 parts of reaction buffer while mixing in a glass tube. This EL activity assay method (which follows the recommendations from the Invitrogen Fluorogenic Phospholipase A Substrates Manual) is optimized to allow measurement of the PLA₁ activity of EL (which preferentially hydrolyzes PL at the sn-1 position). Cells were then incubated at either 22 °C or 37 °C, and fluorescence was monitored with a Synergy Neo2 plate reader with an excitation wavelength of 485 nm and an emission wavelength of 516 nm. Readings were taken at 1 and 30 min, with the 1-minute reading subtracted from the 30-minute reading in order to correct for background fluorescence.

### 2.5. Recombinant EL activity assay

To confirm the effects of ANGPTL4 and ANGPTL4/8 on endothelial lipase, a recombinant EL activity assay was performed by first pre-incubating 80 μL of human recombinant EL protein at a final concentration of 400 nM in reaction buffer (50 mM Tris-HCl, 140 mM NaCl, 2 mM CaCl₂) containing increasing concentrations of ANGPTL4 or ANGPTL4/8. The pre-incubation was allowed to proceed for 1-hour at 37 °C before adding 20 μL of 5X working solution, the same solution as described for the EL cell-based activity assay. The incubation was continued at 37 °C, and fluorescence was monitored with a Synergy Neo2 plate reader with an excitation wavelength of 485 nm and an emission wavelength of 516 nm. Readings were taken at 1 and 30 min, with the 1-minute reading subtracted from the 30-minute reading in order to correct for background fluorescence.

### 2.6. Data analysis

A four-parameter logistic non-linear regression model was used to fit curves for EL activity assays and to estimate IC₅₀ values, which were determined using the sigmoidal 4-PL fittings. For ANGPTL3/8 and ANGPTL4/8 immunoassays, MSD software was used for fitting of the individual calibration curves using a 5-parameter fit with 1/y² weighting. For the correlations of ANGPTL3/8 and ANGPTL4/8 complexes with serum lipid parameters, associations between the complexes and selected markers were assessed using Spearman rank correlation coefficients.

### 3. Results

#### 3.1. ANGPTL3/8 and ANGPTL4/8 correlations with lipid markers in type 2 diabetes

We previously showed in control subjects that ANGPTL3/8 and ANGPTL4/8 complexes increased with feeding to direct FA toward the adipose tissue for storage as TG [15]. Interestingly, we also demonstrated in the same study that levels of both complexes were inversely correlated with HDL while being directly correlated with TG and all other metabolic syndrome markers. Because type 2 diabetes patients often present with increased TG and decreased HDL, we examined circulating levels of ANGPTL3/8 and ANGPTL4/8 in type 2 diabetes patients to determine how these complexes correlated with multiple, different lipid parameters.

ANGPTL3/8 levels in type 2 diabetes patients (mean = 18 ng/mL) were similar to those of normal subjects (mean = 18 ng/mL) while ANGPTL4/8 levels in type 2 diabetes patients (mean = 48 ng/mL) were roughly 2-fold higher than those observed in normal subjects (mean = 22 ng/mL). These results were consistent with our previously reported observations [15]. Because normal subjects were anonymized, however, it was not possible to control or correct for factors such as BMI, which might be altered in type 2 diabetes patients and could thus affect ANGPTL4/8 levels.

As Table 1 demonstrates, in type 2 diabetes patients ANGPTL3/8 and ANGPTL4/8 complexes showed correlations with multiple different lipid markers that were similar to the correlations we had previously observed in normal subjects [15]. ANGPTL3/8 (but not ANGPTL4/8) was directly
correlated with TC, LDL-C, non-HDL-C, and ApoB, likely due to the ability of ANGPTL3/8 (but not ANGPTL4/8) to block hepatic uptake of ApoB-containing particles [15]. Interestingly, however, ANGPTL3/8 was not correlated with the ApoB/LDL ratio (a surrogate for small dense LDL), while ANGPTL4/8 levels were directly correlated with the ApoB/LDL ratio.

We also observed that in the type 2 diabetes patients both ANGPTL3/8 and ANGPTL4/8 showed correlations with TG, HDL, and the TG/HDL ratio that were consistent with correlations previously observed in control subjects [15]. Both complexes were directly correlated with TG and the TG/HDL ratio, while being inversely correlated with HDL-C. In the case of ANGPTL3/8, the inverse correlation with HDL did not achieve significance, while the correlation of ANGPTL4/8 with HDL was statistically significant.

### 3.2. ANGPTL3 and ANGPTL3/8 inhibition of EL activity

In light of these results, we investigated possible reasons for the inverse correlations of ANGPTL3/8 and ANGPTL4/8 with HDL by studying the ability of these complexes, as well as ANGPTL3 and ANGPTL4, to inhibit EL, the enzyme that hydrolyzes PL in HDL. ANGPTL3 is a well-known inhibitor of EL, and it is thought that the decreased HDL concentrations observed in human subjects with ANGPTL3 knockout mutations or in patients treated with anti-ANGPTL3 monoclonal antibodies are due to increases in EL activity [7, 8]. We first examined the effect of ANGPTL3 on EL activity. As Figure 1A shows, at 37 °C, ANGPTL3 alone demonstrated inhibition of EL with an IC50 of 85.4 nM. This was similar to the IC50 we had previously observed for ANGPTL3-mediated LPL inhibition [15]. Interestingly, for ANGPTL3/8, the observed IC50 was 7.9 nM, thus indicating a 10.8-fold increase in EL inhibition for the ANGPTL3/8 complex compared to ANGPTL3 alone. This was in contrast to the much greater increase in LPL inhibition that we previously described for ANGPTL3/8 versus ANGPTL3 [15]. Similar results with regard to EL inhibition by ANGPTL3 and ANGPTL3/8 were obtained when the experiments in Figure 1A were repeated at 22 °C (Figure 1B).

### 3.3. ANGPTL4 and ANGPTL4/8 inhibition of EL activity

We next performed experiments to examine the ability of ANGPTL4 to inhibit EL at 37 °C (Figure 2A). To the best of our knowledge, ANGPTL4 has not been previously described as a inhibitor of EL. We evaluated ANGPTL4 in the same human EL cell-based activity assay used to characterize ANGPTL3 and ANGPTL3/8 and observed that ANGPTL4 inhibited EL activity with an IC50 of 7.2 nM. Remarkably, this was a lower IC50 for EL inhibition than that of ANGPTL3, indicating that ANGPTL4 may be a more potent EL inhibitor than ANGPTL3. Interestingly, in contrast to the increase in EL inhibition observed with ANGPTL3/8 versus ANGPTL3, ANGPTL4/8 manifested decreased EL inhibitory activity, with an IC50 of 121 nM. Thus, ANGPTL4/8 exhibited a 16.8-fold decreased potency for EL inhibition compared to ANGPTL4 alone. This decreased potency for EL inhibition of ANGPTL4/8 versus ANGPTL4 paralleled the trend we had seen for their respective effects on LPL inhibition, although the absolute magnitude of the decreased potency was again less than what we had observed for LPL [15]. When these experiments were repeated at 22 °C (Figure 2B), similar results were again observed for the EL inhibition of ANGPTL4/8 versus ANGPTL4. This was in dramatic contrast to what we had previously observed for ANGPTL4/8-mediated inhibition of LPL, which was markedly decreased at 22 °C versus 37 °C [17].

Table 2 summarizes the results from the EL activity experiments performed with ANGPTL3, ANGPTL3/8, ANGPTL4, and ANGPTL4/8 at both 37 °C and 22 °C. Together, these results show for the first time that ANGPTL4 inhibits EL activity more potently than ANGPTL3. In addition, similar to what we have previously described for LPL, the individual ANGPTL proteins and their respective complexes appeared to exist in an almost symmetrically modifiable system for modulating EL activity. The IC50 values for EL inhibition by ANGPTL3 and ANGPTL4/8 were very similar, as were the IC50 values for inhibition of EL by ANGPTL4 and ANGPTL3/8. Interestingly, the dramatic temperature-dependent decrease in ANGPTL4/8-mediated LPL inhibitory activity that we previously described [17] was not observed for ANGPTL4/8-mediated inhibition of EL activity.
3.4. ANGPTL4 and ANGPTL4/8 inhibition of recombinant EL protein activity

To confirm further the inhibition of EL by ANGPTL4 and ANGPTL4/8, we performed recombinant EL activity assays after first pre-incubating the human recombinant EL protein with increasing concentrations of either ANGPTL4 or ANGPTL4/8 complex. Figure 3 shows the results of these experiments, in which ANGPTL4 was confirmed to be a human recombinant EL inhibitor, consistent with what was observed in the cell-based EL activity assay (IC50 = 17.3 nM). Also similar to what was observed in the cell-based EL activity assay, ANGPTL4/8 had reduced EL inhibitory activity compared to ANGPTL4 (IC50 = 69.4 nM). Overall, these results confirmed that ANGPTL4 and ANGPTL4/8 directly inhibited EL activity, with ANGPTL4/8-mediated EL inhibition again being less than that of ANGPTL4.

4. Discussion

The major findings in this study are 1) ANGPTL4 is a more potent inhibitor of the enzyme EL than ANGPTL3, 2) formation of the ANGPTL4/8 complex results in reduced EL-inhibitory activity compared to ANGPTL4 alone, and 3) ANGPTL4/8 levels are increased in patients with type 2 diabetes and are inversely correlated with HDL levels. To our knowledge, this study is the first to demonstrate that ANGPTL4 is an inhibitor of EL. With an IC50 of 7.2 nM for EL inhibition, ANGPTL4 is actually a several-fold more potent EL inhibitor than ANGPTL3, based on our own observations for ANGPTL3 (IC50 = 71 nM), as well as those previously reported for ANGPTL3 [18]. In addition, formation of the ANGPTL4/8 complex (IC50 = 121 nM) decreased the ability of ANGPTL4 to inhibit EL by approximately 17-fold. This reduction in ANGPTL4/8-mediated EL inhibition compared to ANGPTL4 would have expected to lead to overall increased EL activity, and therefore increased hydrolysis of PL present in HDL, which would in turn result in decreased HDL.

These observations may provide an additional reason for why HDL decreases in the postprandial state [19, 20, 21], since the increased ANGPTL4/8 levels that occur after feeding would be predicted to result in decreased EL inhibition. The resulting increase in EL activity would result thus in decreased postprandial circulating HDL. Our findings with regard to ANGPTL-mediated EL inhibition might also help explain why HDL levels are inversely correlated with ANGPTL4/8 concentrations in patients with type 2 diabetes, as the increased ANGPTL4/8 levels in these patients would result in decreased EL inhibition, resulting in increased hydrolysis of PL present in HDL and thus decreased HDL. Interestingly, we once again observed that ANGPTL4/8 levels in type 2 diabetes patients were about twice as high as those of normal controls, while ANGPTL3/8 levels were similar to...
those of normal subjects [15]. Clearly, additional work will be required to understand the reasons for the increased ANGPTL4/8 levels in type 2 diabetes.

Our observations may also shed light on the relatively modest decreases in HDL observed after administration of an anti-ANGPTL3 monoclonal antibody [7]. If ANGPTL3 were the most important inhibitor of EL activity, then administration of a high dose of a therapeutic anti-ANGPTL3 neutralizing antibody would be expected to cause a more precipitous drop in circulating HDL levels than the 20–30% decreases that have so far been reported [7]. Another possibility might be that an anti-ANGPTL3 antibody could also neutralize ANGPTL3 present in the circulating ANGPTL3/8 complex. Since ANGPTL3/8 is roughly as potent an EL inhibitor as ANGPTL4, this could result in decreased ANGPTL3/8-mediated inhibition of EL, thus resulting in increased EL activity, which would in turn be expected to cause HDL levels to decrease. Interestingly, ANGPTL3 inactivation (but not ANGPTL4 inactivation) has also been associated with a cholesterol-reducing effect [8]. One possible explanation for this, which does not involve EL inhibition, may be that the ANGPTL3/8 complex blocks the ability of LPL to facilitate hepatic cholesterol-containing lipoprotein particle uptake, while the ANGPTL4/8 complex does not [15].

Similar to what we previously reported for LPL activity, the individual ANGPTL3 and ANGPTL4 proteins and their respective complexes appear to comprise an almost symmetrically modifiable system for the inhibition of EL activity. Although not identical, ANGPTL3 and ANGPTL4/8 share similar IC50 values for inhibition of EL, as do ANGPTL4 and ANGPTL3/8. A major, unanswered question, however, is why the IC50 values for EL inhibition for each of the individual ANGPTL proteins and complexes are so much greater than the corresponding IC50 values for the same ANGPTL proteins and complexes with regard to their inhibition of LPL. For instance, the most potent LPL inhibitors ANGPTL4 and ANGPTL3/8 have IC50 values for LPL inhibition of 0.29 and 0.14 nM respectively [15], while their IC50 values for EL inhibition are 7.2 nM and 7.9 nM respectively. More investigation will certainly be required in order to understand the reasons for these large differences in the absolute IC50 values for EL versus LPL inhibition.

In the case of the human ANGPTL8 heterozygous knockout mutations (121X and 131X), decreased circulating ANGPTL3/8 complex would be anticipated to result in reduced ANGPTL3/8-mediated EL inhibition, with the expected result being increased EL activity and reduced HDL [22, 23]. In fact, however, the opposite has been reported. Individuals carrying these mutations actually have HDL increases ranging from 6-10 mg/dL [22, 23]. Therefore, these mutations cannot directly be driving the HDL increases through ANGPTL3/8-mediated EL inhibition. Rather, our data suggest that what might be occurring is that ANGPTL8 knockout causes decreased levels of ANGPTL4/8 (and correspondingly increased levels of ANGPTL4 alone). This would result in increased EL inhibition by ANGPTL4 leading to increased HDL. Of course, this possibility will have to be tested by measuring ANGPTL3/8 and ANGPTL4/8 levels in ANGPTL8-knockout subjects.

Taken together, our data show that the ANGPTL8-4-3 system of proteins regulates EL activity in a manner somewhat similar to its regulation of LPL activity. In particular, just as ANGPTL4 is a more potent LPL inhibitor than ANGPTL3, so too is ANGPTL4 a more potent EL inhibitor than ANGPTL3. In the case of both LPL and EL, when ANGPTL8 combines with ANGPTL3 to form an ANGPTL3/8 complex, the potency of ANGPTL3-mediated inhibition is greatly increased, while when ANGPTL8 combines with ANGPTL4 to form an ANGPTL4/8 complex, the potency of ANGPTL4-mediated inhibition is greatly reduced. Although the mechanisms of ANGPTL4 and ANGPTL3/8 inhibition of LPL are reasonably well described [24, 25, 26, 27, 28, 29, 30], further study will certainly be required to elucidate the biochemical mechanisms governing EL inhibition by ANGPTL4 and ANGPTL4/8.

5. Conclusions

By demonstrating that ANGPTL4 is an inhibitor of EL while ANGPTL4/8 has decreased EL-inhibitory activity, we show that the ANGPTL8-4-3 system of proteins regulates EL activity in a symmetrically modifiable manner analogous to its regulation of LPL activity. In the case of each enzyme, ANGPTL8 forms complexes with ANGPTL3 and ANGPTL4 to increase or decrease markedly their respective abilities to inhibit the activities of both lipases.

Declarations

Author contribution statement

Yan Q. Chen: Conceived and designed the experiments; Performed the experiments; Analyzed and interpreted the data.
Thomas G. Pottanat: Performed the experiments; Analyzed and interpreted the data.
Robert W. Siegel, Mariam Ehsani, Yue-Wei Qian: Contributed re-agents, materials, analysis tools or data.
Robert J. Konrad: Conceived and designed the experiments; Wrote the paper.

Funding statement

Robert J. Konrad was supported by Eli Lilly and Company.

Data availability statement

Data will be made available on request.

Declaration of interests statement

The authors declare no conflict of interest.

Additional information

No additional information is available for this paper.

Acknowledgements

We thank Melissa Bellinger for assistance with cell lines and EL activity assays.
