Patterns of inhibition of human protein-tyrosine phosphatase IB and aldose reductase by Moringaoleifera lam leaves extract

Abstract
Insulin resistance is the main feature of Type 2 diabetes, due to attenuated or diminished signaling from insulin receptors, resulting in hyperglycemia. Inhibition of protein tyrosine phosphatase IB (PTP1B) has been suggested as an attractive target to improve insulin sensitivity in different cell types. In addition, hyperglycemia activates the intracellular polyol pathway causing accumulation of sorbitol. This results in cellular water and electrolyte imbalance and oxidative injury. Aldose reductase inhibitors block the rate-limiting enzyme of the polyol pathway, decreasing the accumulation of sorbitol. Moringaoleifera is a plant widely used in traditional Indian and African medicine, eg. for its antidiabetic effect. However, studies about the inhibition of PTP1B and aldose reductase have not been carried out yet. To potentially identify targets responsible for this antidiabetic effect, we conducted kinetic studies to investigate the inhibitory capacity of M. oleifera extract (MOE) over PTP1B. MOE possesses the highest inhibitory activity against PTP1B (IC50 value of 346.8µg/mL). We also found that the extract inhibited the recombinant human aldose reductase (rhAR) activity with an IC50 of 3.55µg/mL. Subsequent kinetic analysis revealed that MOE behaved as an uncompetitive inhibitor (Ki of 19.65µg/mL) against PTP1B, since it markedly modified Km and also modified Vmax to a lesser extent. As for the rhAR, the extract behaved as mixed inhibitor (Ki=18.6µg/mL, alpha=1.3). Our results help to understand the inhibition mechanism of PTP1B and rhAR by phenolic compounds and flavonoids present in MOE, which is essential for the development of improved natural inhibitors.

Keywords: moringaoleifera, PTP1B, rhAR, enzymatic inhibitors, diabetic complications

Introduction
The protein tyrosine phosphatase (PTP) member of super family enzymes functions in a coordinated manner with protein tyrosine kinases. It plays a critical role in the regulation of a broad spectrum of cellular processes such as growth, proliferation and differentiation, metabolism, immune response, cell-cell adhesion, and cell matrix contacts. Among these, Protein tyrosine phosphatase IB (PTP1B) is a major non-transmembrane phosphoprotein having widely expressed in human skeletal muscle, liver, adipose tissue and brain. In regard to type2 diabetes (T2DM), PTP1B acts by dephosphorylating specific phosphoprotein residues on the insulin receptor (IR) and insulin receptor substrate proteins 1 (IRS-1) and 2 (IRS-2). Phosphorylated IRS activates several signaling cascades that mediate the biological effects of insulin including glucose uptake and glycogen synthesis. Thus, a number of genetic and biochemical studies have demonstrated that PTP1B is a major negative regulator of insulin receptor signaling. For instance, PTP1B deficiency enhances insulin signaling and sensitivity in skeletal muscle and liver. PTP1B-null mice displayed enhanced tyrosine phosphorylation of IR and IRS-1 in muscle and liver as a consequence of increased systemic insulin sensitivity. Moreover, these PTP1B-null mice were less prompt to develop T2DM and obesity when fed with a high fat diet. In addition, liver-specific deletion of PTP1B attenuates metabolic syndrome and diet-induced endoplasmic reticulum stress in mice. Based on these findings, inhibition of PTP1B is expected to improve insulin action, and PTP1B inhibitors have received considerable attention as novel therapies to T2DM and obesity.

On the other hand, aldose reductase (AR) is NADPH-dependent aldo-keto oxidoreductase, which is the first enzyme in the polyol pathway. This enzyme catalyzes the reduction of glucose to sorbitol via the oxidation of NADPH. During hyperglycemia, the increased glucose flux enters to polyol pathway leading to an overflow of sorbitol and its metabolites (i.e. fructose), followed by accumulation within the cells due to their poor permeation across membranes and inefficient metabolism making this pathway one of the leading causes of diabetic complications. Aldose reductase inhibitors (ARIs) have been studied in vivo to evaluate their effectiveness in the prevention of diabetes-related complications in experimental animals and clinical trials. Although several synthetic ARIs exhibit potent inhibitory effects, either their use is limited, or they have been withdrawn from clinical trials because of their relatively low efficacy, poor pharmacokinetics and potential side effects. Furthermore, ARIs may be able to prevent or delay the onset of cardiovascular complications related to secondary diabetic complications.

It is well established that natural products are excellent sources of chemicals that may be therapeutically attractive agents for the prevention and/or treatment of diabetic complications. Previous studies on Moringaoleifera have revealed that it possess potent antioxidant, antimicrobial and antipyretic properties which have been used in traditional Indian and African medicine for centuries. The plant is credited to contain important amounts of phenolic compounds and flavonoids like quercetin, rutin, kaempferol, astragal in and luteolin that possess diverse pharmacological and therapeutic actions. Among these, much attention has been paid to the influence of M. oleifera on insulin action, which may provide benefits for

diabetic patients. Moreover, there is increasing interest in the use of M. oleifera to treat some pathological conditions linked to oxidative disorders that include diabetes, and cancer.10

Some studies showed that MOE decreased streptozotocin-induced hyperglycaemia since it possesses potent hypoglycemic effects through the normalization of elevated hepatic pyruvate carboxylase (PC) enzyme and regeneration of damaged hepatocytes and pancreatic β cells. In addition, it has been reported to contain compounds with strong inhibitory capacity against carbohydrate and lipid digestive enzymes.11 More recently, it was reported the inhibition of angiotensin I-converting enzyme and arginase activities in a dose-dependent pattern with IC_{50} values of 303.03 and 159.59µg/mL, respectively.12 Although some studies have demonstrated the potential inhibitory activity of phenolic compounds and flavonoids present in MOE, only few studies discussed about the inhibition mode of these compounds, none examined its inhibitory activities against AR, and PTP1B. Therefore, the aim of this study was to investigate its inhibitory activity of M.oleiferae and MOE and AR in vitro.

Materials and methods

Reagents

DL-glyceraldehyde, the reduced form of nicotinamide adenine dinucleotide phosphate (NADPH), p-nitro phenyl phosphate (pNPP) and recombinant human aldose reductase (rhAR) were purchased from Sigma-AldrichQuimica, S.L (Mexico).

Expression and Purification of recombinant PTP1B

Cloning PTPN1 gene into over expression plasmid PET28a using E. coli BLR strain produced recombinant human PTP1B; enzyme purification was made by affinity chromatography as detailed elsewhere.13

Preparation of MOE

Hydro alcoholic extract of dried M. oleifera leaves was prepared as described in our previous report. Briefly, the extract was prepared using 23g of dry-ground sample and 260mL of 80% methanolic aqueous solution by successive maceration. The mixtures were shaken in a magnetic grid at room temperature for 21h, and then filtered through a Whatman filter paper number 1. The final extract was concentrated on a rotary evaporator, placed in a deep freezer for 24h and freeze-dried to obtain a powdered extract.

PTP1B activity assay

The enzyme reactions were carried out using standard conditions essentially as described by Goldstein and Bittner-Kowalczyk.14 The assay conditions were as follow. Appropriately diluted inhibitors (4 different concentrations: diluted 1, 3, 9, and 27 fold) were added to the reaction mixtures containing different concentrations of the substrate, p-nitrophenyl phosphate (pNPP) (usual range: 1 to 20mM, final assay concentration). The assay buffer 50mMHepe pH 7.0, contained150mM sodium chloride, 1mMthioditol (DTT), and 1mMEDTA (final volume of 500µL). The reaction was started by the addition of the enzyme and carried out at 37°C for 5min. The enzyme activity was determined by measuring the changes in absorbance at 405nm with appropriate corrections for absorbance of the MOE and pNPP. The data were analyzed using nonlinear regression hyperbolic fit to classical Michaelis-Menten enzyme kinetic models. Inhibition is expressed as IC_{50} values in µg/mL.

Kinetics of rhAR inhibition by MOE

Reaction mixtures consisted of 0.1M potassium phosphate (pH 6.0), 0.2mM NADPH, 1µg/mL of rhAR with varied concentrations of DL-glyceraldehyde (DL-GAL; 40-400µM) in a total volume of 600µL. Enzyme activity was assayed spectrophotometrically by measuring the decrease absorbance at 340nm after NADPH addition using Hatch 5000 spectrophotometer. Line weaver-Burk plot analysis was determined calculated from the data according to Michaelis-Menten kinetics in order to understand the probable mode of inhibition using Sigma plot 12.3 software. Samples were prepared in replicates and analyzed two twice.

Inhibition studies

PTP1B activity was measured by addition of 10µL of 100mmol/ LpNPP (as substrate) into a buffer solution (pH 7.0) containing 50mMHepe, 100mMNaCl, 1mMEDTA, 1mM DTT, DMSO 10% and 50µg/mL recombinant PTP1B, along with or without different concentrations of MOE diluted in reaction medium. After incubation for 5min at 37°C, the reactions were stopped with 0.1M NaHCO3. The amount of p-nitrophenol (pNP) was measured by UV absorbance at 405nm. The percentage of inhibition was calculated considering the activity in the absence of MOE as 100%. The IC_{50} value was determined by non-linear regression analysis plot of percent inhibition versus log inhibitor concentration.

Results

Typically, high-throughput screening assays seek a total inhibitor concentration that reduces the activity by 50 % (IC_{50}). So initially, we determined the IC_{50} for the MOE. The PTP1B inhibition studies demonstrated that MOE had inhibitory activity. In all experiments, control samples were prepared without any plant extract and were compared with test samples containing various concentrations of the plant extract. The concentration of substrate used was 25mM, and PTSB6 small compound inhibitor was used as the positive control (data not shown). As shown in Figure 1, results of inhibitory assays on PTP1B activity showed that MOE had moderate activity, with an IC_{50} value of 346.8±2.5µg/mL. While, MOE showed the highest inhibitory activity against rhAR (IC_{50}=3.55µg/mL, Figure 1B).

Figure 1 Inhibition of human PTP1B and rhAR by MOE. A) Inhibition of PTP1B activity by MOE at various concentrations (100-500µg/mL). The PTP1B inhibition was analyzed by measuring p-NP released from p-NPP at 405nm after 5min of incubation at 37°C. B) Inhibition of rhAR activity by MOE at various concentrations (0.5-50µg/mL). The rhAR inhibition was analyzed by measuring NADP* released from NADPH at 340nm after 2 min of incubation at 25°C. IC_{50}=3.55µg/mL. Results are expressed as mean of percent inhibition±SEM against log 10 concentration of inhibitor.

Once the IC_{50} assays had revealed that MOE have a moderate and high inhibitory activity against both enzymes respectively, and that the IC_{50} value depends on enzyme and substrate concentrations, and type of inhibitor along with other experimental conditions. It was necessary to determine the K_{i} value and the inhibition mechanism performed by MOE. Thus, to assess the mechanism of MOE inhibition on PTP1B and rhAR activities, the potential effects of MOE on the Michaelis constant (k_{m}) and/or the maximal velocity of the reaction (V_{max}) were determined by increasing concentrations of substrates (pNPP and DL-GAL) and 50 or200µg/mL of MOE as inhibitor.
As shown in Figure 2A, the rate of pNPP decomposition by human PTP1B displayed a Michaelis-Menten behavior. An estimation of \( V_{\text{max}} \) and \( K_m \) can be made from these data. In the absence of MOE, the \( V_{\text{max}} \) was calculated to be 129.9±0.05 mmol/min/mg using nonlinear regression analysis with the function provided by Sigma plot program v12.3. In addition, nonlinear curve fitting of the data to the Michaelis-Menten equation yielded a \( K_m \) of 2.2±0.3 mM, a \( k_{\text{cat}} \) of 12.9±0.5 s\(^{-1}\) and a \( K_m/k_{\text{cat}} \) of 5.8 s\(^{-1}\) mM\(^{-1}\). Our results are similar to that reported by Sarmiento.\(^{16}\)

According to our results, there are remarkable differences on the inhibitory potency of MOE against PTP1B and rhAR. These differences can be attributed to the inhibition mechanism produced and as a result of different degrees of bulk tolerance for these enzymes. However, it is essential to perform comprehensive examinations of flavonoids presents in MOE that function as inhibitors against PTP1B and rhAR.

\( V_{\text{max}} \) and \( K_m \) were calculated from the Lineweaver-Burk plots (Figure 2B). The \( V_{\text{max}} \) for control was 129.9±0.05 mmol/min/mg, while the \( V_{\text{max}} \) for 200 µg/mL of MOE was 58.3±1.6 mmol/min/mg. The \( K_m \) for control was 2.25 mM, while the \( K_m \) for 200 µg/mL of MOE was 0.8±0.15 mM. These results indicate that the inhibition of PTP1B by MOE was uncompetitive, so MOE is more likely to bind to the substrate-enzyme complex.

To assess the aldose reductase inhibition activities of MOE, rhAR was used. This enzyme is available in a pure form and has been widely used in medical research as a model for screening potential inhibitors. In the present study, we have evaluated the potential inhibitory activity of the MOE against rhAR. MOE showed a high percentage inhibition (with IC\(_{50}\) value of 0.55 µg/mL) on rhAR activity (Figure 3). Hyperbolic initial velocity as a function of substrate concentration (DL-GAL) was plotted as a linear function of reciprocal of initial velocity against the reciprocal of DL-GAL concentration (Lineweaver-Burk plot) at the presence or absence of MOE. The double-reciprocal plots showed a family of lines intersecting to the left on the y-axis (Figure 3B), which is consistent with mixed inhibition. The kinetics parameters of rhAR were \( V_{\text{max}} \) of 498.6 nmol/min/mg, \( k_{\text{cat}} \) of 0.223 mM, \( K_m \) of 0.223 mM, \( K_{\text{m}} \) of 18.6 µg/mL, and alpha factor of 1.3.

According to our results, there are remarkable differences on the inhibitory potency of MOE against PTP1B and rhAR. These differences can be attributed to the inhibition mechanism produced and as a result of different degrees of bulk tolerance for these enzymes. However, it is essential to perform comprehensive examinations of flavonoids presents in MOE that function as inhibitors against PTP1B and rhAR.

Discussion

Protein Tyrosine Phosphatases (PTPs) are essential in the metabolic system to regulate physiological functions of cells. However, a number of diseases like diabetes, obesity and cancer are reported to be induced by over-activity of PTPs.17 Hence, regulation of PTP1B activity through specific inhibitors is an excellent target to the development of new treatments for diabetes.

Natural products gained attention for long-term treatment of metabolic diseases due to their multifunctional components and multipronged mode of action. To date, the reports on the inhibitory activities of medicinal plants extracts against PTP1B are still limited. However, several PTP1B inhibitors have been isolated from medicinal plants to develop an alternative drug with higher potency and lesser adverse effects.18 M. oleifera has been used since ancient times in traditional medicine to treat diabetes, and it was found to have insulin sensitizing properties.19 Along with the antidiabetic effect, its leaves have been reported to possess antioxidant activity,20 and anti-dyslipidemic properties.21 Hence, their traditionally reported antidiabetic activity could be due to PTP1B inhibition.

To our knowledge, there is no report on the inhibitory potential role of MOE on PTP1B activity. In our study, methanolic extract of M. oleifera was tested to evaluate its PTP1B inhibitory potential. The extract remarkably inhibited the activity of PTP1B with an IC\textsubscript{50} value in the range of 322-378µg/mL (Figure 1). This activity is lower than the reported values for a variety of vegetables22 and seaweed.23

Previous photochemical studies on Moringa oleifera revealed the presence of polyphenols, flavonoids and other compounds.25 Our previous results of photochemical analysis of M. oleifera also showed the presence of flavonoids and phenolic compounds.26 Here we provide evidence that MOE containing metabolites inhibited PTP1B activity, while no effects were observed by isolated compounds (caffeic acid, catechins and siringic acid), except by rutin and Gallic acid which presented moderate inhibition effects (data not shown). Further investigation is necessary to confirm which of the components from MOE were responsible to inhibit the PTP1B. However, it is highly probable that a synergic effect from the combination of its bioactive components does contribute to the strong inhibitory effect.

There are studies that suggested that individual components asursolic acid, tormentic acid, palmitic acid, and flavonoids isolated from the roots of the Broussonetia papyrifera inhibited PTP1B,26 but the mechanism involved in the inhibition remained to be defined. Nevertheless, it was reported that glisoflavone isolated from the roots of Glycyrrhizauralensis showed the strongest inhibitory activity of PTP1B, with an IC\textsubscript{50} of 27.9µmol/L, in a mixed-type manner.27 Furthermore, MeOH extract of Selaginellatamariscina was found to inhibit PTP1B at 30µg/mL, and its bioassay-guided fractionation of the extract producedamentoflavone, a non-competitively inhibitor with K\textsubscript{i} value of 5.2µM.28 In a similar manner, MOE showed a strong inhibitory activity against PTP1B with i\textsubscript{50} of 40µg/mL in a mixed-uncompetitive type manner.

Our data are also in agreement with other studies in which several natural products were shown to inhibit PTP1B, including phenylated flavonoids from the root bark of Erythrina中国政府,29 isoprenylated flavonoids from Ficus Jesús and tea catechins.31 Therefore, significant results of inhibitory capacity in MOE can be attributed to the presence of diverse compounds. No obstacle, further studies are needed to understand how M. oleifera leaf extract mediate the inhibitory effects on PTP1B and determine whether phenolic compounds, flavonoids and triterpenoids are the major active components responsible for MOE inhibitory potential as well as to identify other potential compounds involved.

The AR is implicated in the development of diabetic complications by catalyzing the reduction of glucose to sorbitol.32 It participates in diabetes associated mitochondrial disorder and damage via the activation of p53.33 Moreover, polymorphic markers of the human AR gene demonstrate a strong association with susceptibility to develop diabetic complications. Although a number of ARIs have been tested or are currently undergoing to clinical trials, the clinical efficacy is uncertain and there are concerns with associated adverse effects such as hepatic damage.3 Hence, it is necessary to found new natural compounds.

A number of common plant/natural products used in Indian gastronomy have been evaluated for their AR inhibitory potential. Among the 22 dietary sources tested, 10 showed considerable inhibitory potential against both rat lens and rhAR with an approximate IC\textsubscript{50} of 0.2mg/mL.34 Although the M. oleifera is an Indian native tree and is part of its population’s diet, it was not considered in this study. Previous studies have shown that the active components of the aqueous extract from Emblica officinalis fruit penetrate the lens and substantially delay the progression of cataracts through aldose reductase 2 inhibition.35 Kinetics studies have suggested that is flavones isolated from Caesalpinia pulcherrima can interact and inhibit the AR in a non-
competitive manner, suggesting its potential to combine with both, the free enzyme and the enzyme-substrate complex.\textsuperscript{36} As reported by Tae Hyeon Kim et al.,\textsuperscript{37} through bioassay-guided fraction of an EtOH extract of the kernel from purple corn (Zea mays L.) showed that hirsutrin have rhAR inhibitory activity (IC\textsubscript{50} 4.78µM) and kinetic analyses using Line weaver-Burk plots hirsutrin showed a competitive inhibition against rhAR. However, it was reported that compounds that selectively bind to the enzyme-nucleotide complex are more effective than those bind to free enzyme.\textsuperscript{38}

In our study, MOE showed a significant inhibition of rhAR with an IC\textsubscript{50} value of 3.55µg/mL in a mixed manner, which suggests that compounds present in this extract may be bind both the enzyme-nucleotide complex and free enzyme. In addition, these results suggest that MOE could serve as source of leading compounds for potential analogues with improved inhibitory activity. Therefore, the presence of biologically important photochemical in this extract may be useful for pharmaceutical therapies. Further studies towards fractioning, isolation and purification of active principles from M. oleifera extract are in progress in our laboratory.

Conclusion

The data obtained in the present study confirmed that methanolic extract of M. oleifera possess inhibitory potential against both PTP1B and rhAR activities. Our findings suggest that MOE have potential to be used in the treatment of diseases associated with over activity of PTP1B. These results also indicate that MOE is an effective inhibitor of rhAR. Moreover, the information provided by this analysis suggest that the antidiabetic effects of M. oleifera extract are attributable not only to the insulin receptor but may also block the participation of AR in diabetes-associated mitochondrial disorder and damage via the activation of p53, confirming the use of M. oleifera as a treatment of diabetes in traditional medicine.
