INTEGRATION OF LIE ALGEBROID COMORPHISMS

ALBERTO S. CATTANEO, BENOIT DHERIN AND ALAN WEINSTEIN

Abstract. We show that the path construction integration of Lie algebroids by Lie groupoids is an actual equivalence from the category of integrable Lie algebroids and complete Lie algebroid comorphisms to the category of source 1-connected Lie groupoids and Lie groupoid comorphisms. This allows us to construct an actual symplectization functor in Poisson geometry. We include examples to show that the integrability of comorphisms and Poisson maps may not hold in the absence of a completeness assumption.

1. Introduction

A classical result in differential geometry is that any finite dimensional Lie algebra \( \mathfrak{g} \) can be integrated by a 1-connected Lie group \( \Sigma(\mathfrak{g}) \) (conversely, any Lie group endows its tangent space at the unit with the structure of a Lie algebra). This bijective correspondence between finite dimensional Lie
algebras and 1-connected finite dimensional Lie groups is actually the object component of an integration functor

$$\Sigma : \text{LieAlg} \to \text{LieGp},$$

which is an equivalence from the category of finite dimensional Lie algebras to the category of finite dimensional 1-connected Lie groups.

There are several generalizations of finite dimensional Lie algebras: infinite-dimensional (e.g Banach) Lie algebras, Lie algebroids, Poisson manifolds, and $L_\infty$-algebras, for instance. In each case, it is natural to ask whether there is a corresponding integration functor. For this, we need to find out the right notion for the objects integrating these generalized Lie algebras as well as the right notion of morphisms between them.

We will be concerned here with Lie algebroids and Poisson manifolds (see [14] for a general reference), each of whose have natural integrating objects: Lie groupoids for Lie algebroids and symplectic groupoids for Poisson manifolds.

However, unlike finite dimensional Lie algebras, not all Lie algebroids are integrable by Lie groupoids. In [8], Crainic and Fernandes worked out a criterion to select those that are. In this paper, we will construct an integration functor for the class of integrable Lie algebroids. To allow non-integrable Lie algebroids to be in the domain of an integration functor, one must consider integration by microgroupoids (i.e. germs of groupoids) in the spirit of [5] or by differentiable stacks as in [19].

We will focus on an integration functor for Lie algebroids that translates into an integration functor for Poisson manifolds (also called “symplectization functor” by Fernandes [9]). For this, the main ingredient is to replace the usual notion of morphisms between Lie groupoids (i.e. smooth functors between the underlying groupoids, see [11, 14]) and their corresponding infinitesimal version for Lie algebroids by that of comorphisms. Lie algebroid and Lie groupoid comorphisms were introduced by Higgins and Mackenzie in [12]. (This notion for Lie groupoids had been studied earlier under a different name and with a different, but equivalent, definition by Zakrzewski in [20] and Stachura in [18].) Already there, comorphisms were seen as the “correct” notion of morphisms between Lie algebroids to be used with applications to Poisson geometry in mind.

From the perspective of Poisson geometry, Lie algebroid and Lie groupoid morphisms are not very well-suited, since a Poisson map $\phi$ from $X$ to $Y$ induces a Lie algebroid morphism from $T^*X$ to $T^*Y$ (that integrates to a symplectic groupoid morphism) only when $\phi$ is a diffeomorphism. This prevents us from constructing an integration functor whose domain would contain all Poisson maps. On the other hand, the cotangent map $T^*\phi$ to a Poisson map $\phi$ is always a comorphism from $T^*X$ to $T^*Y$.

There are also a number of facts independent of Poisson geometry that make comorphisms the “correct” notion of morphisms between Lie groupoids. For
instance, a comorphism between Lie groupoids naturally induces a group morphism between the corresponding groups of bisections as well as a $C^\ast$-algebra morphism between the corresponding convolution $C^\ast$-algebras (see [18]). This gives functors from the category of Lie groupoids and comorphisms to the category of groups and to the category of $C^\ast$-algebras (see [15]). Moreover, the graph of a Lie groupoid comorphism is a monoid map in the “category” of differentiable relations between the monoid objects associated to the multiplication graph of the corresponding Lie groupoids (see [20]).

On the other hand, in contrast to Lie algebroid morphisms, Lie algebroid comorphisms do not always integrate to Lie groupoid comorphisms. The same holds in Poisson geometry, where completeness of Poisson maps insures integrability in terms of (symplectic) comorphisms. We will give an example of a non complete Lie algebroid comorphism that is also non integrable, and whose dual is a non complete and non integrable Poisson map.

Dazord in [10] already stated without proof that both complete Lie algebroid comorphisms and Poisson maps always do integrate to comorphisms. In [20], Zakrzewski proved that complete Poisson maps are integrable to what he called “morphisms of regular $D^\ast$-algebras,” which turn out to be nothing but symplectic comorphisms.

More recently, Caseiro and Fernandes in [1] proved that a complete Poisson map $\phi$ from integrable Poisson manifolds $X$ to $Y$ always integrates to a natural left action of the symplectic groupoid $\Sigma(Y)$ on $X$ with moment map $\phi$. This action naturally induces an embedded lagrangian subgroupoid integrating the graph of the Poisson map. Their proof, at contrast with the one of Zakrzewski which uses the method of characteristics, is readily transposable to complete Lie algebroid comorphisms. They use the existence of lifting properties by complete Poisson maps for both admissible paths and their homotopies, which also holds for complete Lie algebroid comorphisms and makes them resemble “Serre fibrations” in topology.

These lifting properties (Proposition 9 and 10) will also be central to our main result (Theorem 12): namely, that the path construction of [4, 8, 7], which associates a source 1-connected Lie groupoid $\Sigma(A)$ to each integrable Lie algebroid $A$, is an actual equivalence from the category of integrable Lie algebroids and complete Lie algebroid comorphisms to the category of source 1-connected Lie groupoids and Lie groupoid comorphisms.

As a corollary, we obtain that Lie algebroid comorphisms are integrable if and only if they are complete, which strengthens Dazord’s statement. We show that this implies a corresponding theorem in Poisson geometry, where the path construction implements an equivalence between the category of integrable Poisson manifolds and complete Poisson maps and the category of source 1-connected symplectic groupoids and symplectic comorphisms. From this, we may conclude that Poisson maps are integrable if and only if they are complete, which was already shown by Zakrzewski in the language of regular $D^\ast$-algebras.

2. Morphisms and comorphisms

Much of what follows in this section may already be found in \[2, 10, 11, 12\]. We work in the smooth category. Let \(a : A \to X\) and \(b : B \to Y\) be submersions, which we may think of as families of manifolds parametrized by \(X\) and \(Y\).

A map \(\phi\) from \(X\) to \(Y\) together with a map \(\Phi\) to \(A\) from the pullback \(f^! B = X \times_Y B\) will be called a comorphism from \(a\) to \(b\); \(\phi\) will be called the core map of the comorphism. When the families are vector bundles and \(\Phi\) is linear on fibres, we call \((\phi, \Phi)\) a vector bundle comorphism. It induces a dual vector bundle map \(\Phi^*\) from \(a^*: A^* \to X\) to \(b^*: B^* \to Y\) covering \(\phi\) and a pullback map \(\Phi^!\) to the space \(\Gamma(A)\) of sections of \(A\) from \(\Gamma(B)\).

On the other hand, a morphism from \(a\) to \(b\) is simply a bundle map, which we also denote by \((\phi, \Phi)\), where the core map \(\phi\) is the base map of the bundle map, and \(\Phi\) is a collection of smooth maps \(\Phi_x\) from the fibers \(A_x\) to \(B_{\phi(x)}\). When \(a\) and \(b\) are vector bundles and \(\Phi\) is linear on fibers, a morphism \((\phi, \Phi)\) is a vector bundle map.

As observed in \[12\], the notions of morphisms and comorphisms for vector bundles are dual to each other in the sense that \((\phi, \Phi)\) is a comorphism from \(a\) to \(b\) if and only if \((\phi, \Phi^*)\) is a morphism from \(a^*\) to \(b^*\) (and conversely).

We now specialize the notion of morphisms and comorphisms to Lie algebroids and Lie groupoids, and we introduce corresponding Lie functors (see also \[11, 12\]).

2.1. Lie algebroids. If \(A\) and \(B\) are Lie algebroids, a vector bundle comorphism \((\phi, \Phi)\) is called a Lie algebroid comorphism if \(\Phi^*\) is a Poisson map for the natural Lie-Poisson structures on the dual Lie algebroids. Equivalently, \(\Phi^!\) is a homomorphism of Lie algebras, and

\[
(\phi_*) \circ \rho_A \circ \Phi = \rho_B ,
\]

where \(\rho_A\) and \(\rho_B\) are the anchor maps of respectively \(A\) and \(B\).

On the other hand, a vector bundle morphism \((\phi, \Phi)\) is called a Lie algebroid morphism if \(\Phi^*\) induces a chain map from Lie algebroid complexes \(\Gamma(\wedge^* B)\) to \(\Gamma(\wedge^* A)\) (see \[11\]).
We denote by $\text{Algd}^+$ the category of Lie algebroids and Lie algebroid \textit{morphisms} and $\text{Algd}^-$ the category of Lie algebroids and Lie algebroid \textit{comorphisms}.

Observe that the graph of both a Lie algebroid morphism and a Lie algebroid comorphism is a Lie subalgebroid of the Lie algebroid product $A \times B$ and that morphisms and comorphisms coincide when the core map is a diffeomorphism.

\textbf{Example 1.} Let $\phi : X \rightarrow Y$ be a smooth map. The tangent map $T\phi$ is a Lie algebroid morphism from $TX$ to $TY$ (seen as algebroids with identity as anchor and the usual Lie bracket on vector fields), while the cotangent map $T^*\phi$ is a Lie algebroid comorphism from $T^*X$ and $T^*Y$ (seen as Lie algebroids with zero anchor and zero bracket). $T\phi$ and $T^*\phi$ are both, at the same time, Lie algebroid morphisms and comorphisms when $\phi$ is a diffeomorphism.

\textbf{Example 2.} If $A = TX$ and $B = TY$ carry the usual Lie algebroid structures (as in the previous example), then $(\phi, \Phi)$ is a comorphism from $TX$ to $TY$ when $\phi$ is a submersion and $\Phi$ is the horizontal lift map of a flat Ehresmann connection over the open submanifold $\phi(X) \subseteq Y$.

\textbf{Example 3.} If $A$ and $B$ are Lie algebras, considered as Lie algebroids over a point, then a Lie algebroid comorphism from $A$ to $B$ is a Lie algebra morphism from $B$ to $A$, while a Lie algebroid morphism from $A$ to $B$ is a Lie algebra morphism from $A$ to $B$.

2.2. \textbf{Lie groupoids.} Now let $G \rightrightarrows X$ and $H \rightrightarrows Y$ be groupoids with target and source maps $l_G, r_G, l_H$ and $r_H$. A comorphism $(\phi, \Phi)$ from $r_G$ to $r_H$ is called a \textbf{comorphism of groupoids} if

1. $\Phi$ takes unit elements to unit elements;
2. it is compatible with the target maps in the sense that, for any $(x, h)$ in the pullback $X \times_Y H$, $(\phi \circ l_G)(\Phi(x, h)) = l_H(h)$;
3. it is multiplicative in the sense that $\Phi(y, h_1)\Phi(z, h_2) = \Phi(z, h_1h_2)$ whenever the products are defined; i.e., when $\phi(y) = l_H(h_2)$.

A groupoid comorphism as above may be represented by its graph $\gamma_{(\phi, \Phi)}$, which is the smooth closed subgroupoid of $G \times H \rightrightarrows X \times Y$ consisting of those pairs $(g, h)$ for which $g = \Phi(r_G(g), h)$. The objects of $\gamma_{(\phi, \Phi)}$ are just the points of the graph of $\phi$, and the projection to $H$ of the source fibre of $\gamma_{(\phi, \Phi)}$ over $(g, \phi(g))$ is a diffeomorphism onto the source fibre of $H$ over $\phi(g)$. These properties characterize those subgroupoids of $G \times H$ which are the graphs of comorphisms.

\textbf{Remark 4.} Zakrzewski in [20] introduced the notion of regular $D^*$-algebra and showed that it coincides with that of Lie groupoid, observing though that their natural morphisms do not correspond to Lie groupoid morphisms. $D^*$-algebra morphisms were further studied by Stachura in [18], who called them simply “groupoid morphisms.” From Lemma 4.1 in [20] and Proposition 2.6 in
One sees that $D^*$-algebra morphisms are exactly the Lie groupoid comorphisms introduced later on by Higgins and Mackenzie in [12]. However, neither Zakrzewski nor Stachura discussed a corresponding notion for Lie algebroids.

A morphism of Lie groupoids is a functor between the underlying groupoids, whose object and morphism components are smooth.

We denote by $\text{Gpd}^+$ the category of Lie groupoids and Lie groupoid morphisms and $\text{Gpd}^-$ the category of Lie groupoids and Lie groupoid comorphisms.

Correspondingly, there are two Lie functors

$$\text{Lie}: \text{Gpd}^\pm \to \text{Algd}^\pm,$$

as defined in [12][14], which agree on objects (i.e. they both send a Lie groupoid to its associated Lie algebroid) but one sends morphisms to morphisms while the other sends comorphisms to comorphisms. Geometrically though, the morphism component of both functors can be defined the “same way,” using the object component. Namely, the underlying graph $\gamma(\phi, \Phi)$ of a groupoid morphism or a groupoid comorphism (which, in both cases, we denote by $(\phi, \Phi)$) from $G$ to $H$ is itself a groupoid (actually, a subgroupoid of $G \times H$). Then $\text{Lie}(\gamma(\phi, \Phi))$ is a subalgebroid of $\text{Lie}(G) \times \text{Lie}(H)$, which is the graph of a Lie algebroid morphism when $(\phi, \Phi)$ is a Lie groupoid morphism and the graph of a Lie algebroid comorphism when $(\phi, \Phi)$ is a Lie groupoid comorphism.

The two Lie functors are essentially the same on Lie algebras, since morphisms and comorphisms are the same in this case except for arrow direction.

2.3. **Integrability and completeness.** We say that a Lie algebroid comorphism between integrable Lie algebroids is integrable if it is in the image of the Lie functor. This means that the (possibly immersed) Lie subgroupoid integrating the comorphism graph (which is a Lie subalgebroid) is, at the same time, a closed embedded Lie subgroupoid and a comorphism (the latter implying the former).

If $A$ and $B$ are the Lie algebroids of groupoids $G$ and $H$, then every Lie algebroid comorphism from $A$ to $B$ may be integrated locally to a groupoid comorphism from $G$ to $H$. In contrast with Lie algebroid morphisms, which are always integrable to Lie groupoid morphisms under a simple connectivity assumption (see [15] Appendix for instance), the global situation for Lie algebroid comorphisms is more complicated. The following example gives a Lie algebroid comorphism whose graph integrates, as a Lie algebroid, to an embedded Lie subgroupoid that is not the graph of a Lie groupoid comorphism.

**Example 5.** The inclusion $i$ of an open subset $X$ in a manifold $Y$ yields the Lie algebroid comorphism $(i, \text{id})$ from $TX$ to $TY$ with the natural Lie algebroid structure. The integration of the Lie subalgebroid $\gamma(i, \text{id})$ is the embedded subgroupoid

$$\{(x, x, x, x) : x \in X\} \Rightarrow X \times Y$$
of the groupoid product \((X \times X) \times (Y \times Y) \rightrightarrows X \times Y\). This is not the graph of a comorphism, although there are partially defined maps (namely the identity restricted to \(X\)) from \(\{x\} \times Y\) to \(\{x\} \times X\) for each \(x \in X\), the union of whose graphs is the integrating subgroupoid.

Although “partially defined” Lie groupoid comorphisms as in the example above still compose, and thus form a category, even worse situations can arise. In general, a Lie algebroid comorphism can be integrated only to what Dazord calls a “relation,” and which we will call a hypercomorphism. A hypercomorphism from \(G \rightrightarrows X\) to \(H \rightrightarrows Y\) consists of a map \(\phi : X \to Y\) and a groupoid \(R\) over the graph of \(\phi\) along with a homomorphism to \(G \times Y\) which is an immersion such that the projection to \(H\) is étale between source fibres of \(R\) and \(H\). It is a comorphism just when these maps between source fibres are diffeomorphisms. The image of the immersion \(R \to G \times H\) is a subgroupoid which can sometimes be neither smooth nor closed, as we will see in the next section.

As we will show in Theorem 12, global integrability in terms of Lie groupoid comorphisms is guaranteed if the source fibres of \(H\) are 1-connected and the Lie algebroid comorphism is complete. This means that the pullback map on sections takes complete sections of \(B\) to complete sections of \(A\), where a section of a Lie algebroid is called complete if the anchor maps it to a complete vector field.\(^1\)

This result on global integrability was first announced in [10] without proof. To the best of our knowledge, such a proof has never appeared, although very close results have been achieved in the context of Poisson geometry for complete Poisson maps (which induce complete Lie algebroid comorphisms as we shall see in Section 6) by Caseiro and Fernandes in [1] and by Zakrzewski in [20]. We will give one in Section 5.1 using the path integration techniques developed recently in [4, 8].

We can already see the following:

**Proposition 6.** Let \(G\) and \(H\) be Lie groupoids over \(X\) and \(Y\) respectively, and let \((\phi, \Phi)\) be a groupoid comorphism from \(G\) to \(H\). Then \((\phi, T\Phi) = \text{Lie}(\phi, \Phi)\) is a complete comorphism from \(\text{Lie}(G)\) to \(\text{Lie}(H)\), where

\[
(T\Phi)(x, v) := D_2\Phi(x, \phi(x))v,
\]

and \(D_2\) denotes the derivative w.r.t. the second argument. In other words, integrable Lie algebroid comorphisms are complete.

**Proof.** To simplify notation, set \(A = \text{Lie}(G)\) and \(B = \text{Lie}(H)\). Let \(s\) be a complete section of \(B\). It induces a complete left-invariant vector field \(\xi^H_s\) on the integrating groupoid \(H\) (see [13, Appendix]), whose corresponding left-invariant flow \(\Psi^H_t\) exists thus for all \(t\). Using \((\phi, \Phi)\), we define a left-invariant

\(^1\)If \(A\) is integrable to a Lie groupoid \(G\), completeness of a section of \(A\) means that the section is the initial derivative of a 1-parameter group of bisections of \(G\).
flow on $G$, which also exists for all times:

$$\bar{\Psi}_t^G(g) = L_g \left( \Phi \left( r_G(g), \Psi_t^H(\phi(r_G(g))) \right) \right),$$

where $L_g(g') = gg'$ is the left-translation in $G$.

On the other hand, the section $(T\Phi)^\dagger$ induces a left-invariant vector field $\xi^{(T\Phi)}_G$ on $G$, whose flow $\Psi_t^G$ projects on the flow $\Psi_t^X$ on $X$ of $\rho_A(T\Phi)^\dagger$, that is,

$$\Psi_t^X(l_G(g)) = l_G(\Psi_t^G(g)).$$

What remains to be proven is that $\Psi_t^G$ coincides with $\bar{\Psi}_t^G$: Since the latter exists for all $t$, this would imply that $\Psi_t^X$ exists for all $t$ and, thus, that the image $(T\Phi)^\dagger$ of a complete section $s$ by $(\phi,T\Phi)$ is complete. To see this, let us check that both flows are flows of the same vector field. Namely, since $\bar{\Psi}_t^G$ is left-invariant, we have that

$$\frac{d}{dt} \bigg|_{t=0} \bar{\Psi}_t^G(g) = DL_g(r_G(g))D2\Phi(r_G(g),\phi(r_G(g))) \frac{d}{dt} \bigg|_{t=0} \Psi_t^H(\phi(r_G(g))),$$

$$= DL_g(r_G(g))(T\Phi)(r_G(g),s(\phi(r_G(g)))),$$

$$= DL_g(r_G(g))((T\phi)^\dagger s)(r_G(g)),$$

which, by definition, coincides with $\frac{d}{dt} \bigg|_{t=0} \Psi_t^G(g)$. \qed

Example 7. Let $(\phi, \Phi)$ be a comorphism between tangent bundle Lie algebroids $TX$ and $TY$. As noted above, this corresponds to a flat Ehresmann connection, i.e. a “horizontal” foliation of $X$ for which the projection of each leaf to $Y$ is étale. The comorphism is complete when the connection is complete in the sense that these projections are all covering maps, i.e. when each path $\sigma : [0,1] \to X$ has a horizontal lift starting at any point in $\phi^{-1}(\sigma(0))$.

To integrate this comorphism to a hypercomorphism between the fundamental groupoids $\pi(X)$ and $\pi(Y)$ integrating $TX$ and $TY$ respectively, we let $R$ be the leafwise fundamental groupoid of the foliation of $X$. This is a (1-connected, but possibly non-Hausdorff) Lie groupoid over $X$ and may hence be considered as a groupoid over the graph of $\phi : X \to Y$. An element of $R$ is a homotopy class of paths with fixed endpoints and contained in a single leaf of the foliation. Let us call these “foliated paths”. Mapping each such class of foliated paths to the homotopy class of paths in $X$ (without the “leafwise” restriction) in which it is contained, and to the class of the image in $Y$, is a groupoid morphism from $R$ to $G \times H$. Restricting this morphism to a source fibre of $R$ and projecting to $\pi(Y)$ takes the homotopy classes of foliated paths beginning at some $x \in X$ to the homotopy classes of paths in $Y$ beginning at $\phi(x)$. A neighborhood, in a source fibre of $R$, of the class of a foliated path $\sigma$ may be identified with a neighborhood of $\sigma(1)$ in its leaf, and a neighborhood of the class of the projected path may be identified with a neighborhood of $\phi(\sigma(1))$ in $Y$. The projection from the first neighborhood to the second is
étale by the definition of a flat Ehresmann connection, so the requirements for
$R$ to be a hypercomorphism are met. We may describe the relation $R$ in rough
terms by saying that it takes a point $x \in X$ and a path $\rho$ in $Y$ beginning at
$\phi(x)$ to its horizontal lift through $x$. But this horizontal lift may not exist if
$(\phi, \Phi)$ is not complete, and it might not be unique since a homotopy of paths
in $Y$ may not have a horizontal lift in the absence of completeness.

3. An example

We give in this section an example of an Ehresmann connection, the graph
of whose integration is neither closed nor embedded.

Let $Y$ be $\mathbb{R}^2$ with cartesian coordinates $(x, y)$ and polar coordinates $(r, \theta)$.
$X$ will be an open subset of $\mathbb{R}^2 \times \mathbb{C} \times \mathbb{R}$ with polar coordinates $(r, \theta)$ on the
first factor, a complex coordinate $z = Re^{i\Theta}$ on the second, and real coordinate
$h$ on the third one. As the notation suggests, $\phi$ will be the projection on the
first factor. $X$ and $Y$ will be 1-connected, so the source 1-connected groupoids
integrating $TX$ and $TY$ will be $X \times X$ and $Y \times Y$. Since $Y$ is 1-connected,
the leaves of any foliation defined by a complete Ehresmann connection over
$Y$ are simply connected and therefore have trivial holonomy.

We define $X$ as $\mathbb{R}^2 \times \mathbb{C} \times \mathbb{R} \setminus J$, where $J$ is the three-dimensional slab
$\{(r, \theta, R, \Theta, h) \mid r = 0, -1 \leq h \leq 1\}$. Although $J$ is of codimension 2, the
restriction on $h$ leaves $X$ simply connected, so that its fundamental groupoid
is still $X \times X$. Nevertheless, we can construct an interesting Ehresmann
connection for the submersion $\phi : X \rightarrow Y$. For $-1 \leq h \leq 1$, the horizontal
subspaces of the connection are spanned by the vector fields $\partial/\partial r$
and $\partial/\partial \theta + \nu(h)\partial/\partial \Theta$, where $\nu$ is a smooth function, not identically zero, supported in the
interval $-\frac{1}{2} \leq h \leq \frac{1}{2}$. This makes sense since $r$ is not zero for these values of
$h$. Outside the support of $\nu$, the vector fields $\partial/\partial r$ and $\partial/\partial \theta$
may be replaced by the cartesian coordinate vector fields $\partial/\partial x$
and $\partial/\partial y$, which extend to the
entire $(x, y)$ plane.

We will think of our Ehresmann connection as a family, parametrized by
$h$, of unitary connections on the trivial complex Lie bundle over $Y$ with fibre
coordinate $z$. The connection form in this description is $i\nu(h)d\Theta$, and the holonomy around a loop encircling the origin in the $(x, y)$ plane is multiplication
by $e^{2\pi i\nu(h)}$. In the region where $-1 \leq h \leq 1$ (and so $r$ is not zero), each leaf
lies in a fixed level of $R$ and $h$ and is a covering of the punctured $(r, \theta)$ plane.
The covering is a diffeomorphism if $R = 0$. For positive $R$, the covering has
$k$ sheets when $\nu(h)$ has order $k$ as an element of $\mathbb{R}/\mathbb{Z}$; this includes the pos-
sibilities $k = 1$ and $k = \infty$. Over the region where $-1 < h < 1$, the leafwise
fundamental groupoid may be parametrized by

$$\Gamma = (\mathbb{R}^+ \times S^1) \times (\mathbb{R}^+ \times \mathbb{R}) \times \mathbb{C} \times (-1, 1).$$

The element

$$\gamma = (r, \theta, r', \tau, z, h)$$
of $\Gamma$ corresponds to the homotopy class of the horizontal path

$$t \mapsto (r + (r' - r)t, \theta + \tau t, e^{i\nu(h)\tau t} z, h), \quad 0 \leq t \leq 1.$$ 

Thus, the source map is

$$(r, \theta, r', \tau, z, h) \mapsto (r, \theta, z, h),$$

and the target is

$$(r, \theta, r', \tau, z, h) \mapsto (r', \theta + \tau, e^{i\nu(h)\tau} z, h).$$

The unit elements of the groupoid are defined by the condition $s = r'$ and $\tau = 0$, while the isotropy groups are defined by $r = r'$, $\tau \in 2\pi\mathbb{Z}$, and $\nu(h)\tau \in 2\pi\mathbb{Z}$.

We now look at the leafwise fundamental groupoid as the integration of the Lie algebroid comorphism given by the flat Ehresmann connection. The Lie algebroid sits inside $TX \times TY$; since $X$ and $Y$ are simply connected, the integrating subgroupoid $S$ should sit inside $X \times X \times Y \times Y$; it is the image of $\Gamma$ under the target-source map

$$(r, \theta, r', \tau, z, h) \mapsto \left( (r, \theta, z, h), (r', \theta + \tau, e^{i\nu(h)\tau} z, h), (r, \theta), (r', \theta + \tau) \right).$$

To study the immersion of $\Gamma$ into $X \times X \times Y \times Y$, we can forget about the last two factors, since they are redundant (namely, the image of $\Gamma$ lies in the graph of $\phi \times \phi$, which can be identified with $X \times X$). This image consists of all 8-tuples $(r, \theta, z, h, r', \theta', z', h')$ for which there exists $\tau$ such that $\theta' = \theta + \tau$, $z' = e^{i\nu(h)\tau} z$, and $h' = h$. The two conditions involving $\tau$ can be combined, with the elimination of $\tau$, to give $z' = e^{i\nu(h)(\theta' - \theta)} z$. Where $z$ is nonzero, these define, for each $h$, a hypersurface in the 4-torus with coordinates $(\theta, \arg z, \theta', \arg z')$. The subgroupoid $S \subset X \times X \times Y \times Y$ sits as a family of these hypersurfaces inside the 8-dimensional submanifold defined by $|z'| = |z|$ and $h' = h$, which is a bundle of these 4-tori over the space parametrized by $(r, z, h)$.

From this description, we see immediately that $S$ is not closed. In fact, when $\nu(h)$ is irrational, each of our hypersurfaces is dense but not closed in its 4-torus. To see that $S$ has nontrivial self-intersections, we must look at the section $z = 0$ of our complex line bundle, since otherwise we are simply dealing with flat hypersurfaces in tori. In fact, when $z = 0$, adding an integer multiple of $2\pi$ to $\tau$ does not change the value of the target-source map, but it does change the image of the derivative as long as $\nu(h)$ is not an integer. This results in the sought-for nontrivial self-intersections.

4. Path construction

In this section, we start by briefly recalling the integration of Lie algebroids by Lie groupoids in terms of quotients of certain admissible path sets by homotopies, as in [4, 7]. We explain how this path construction allows us to
integrate comorphisms between Lie algebroids to comorphisms between Lie groupoids. Then we show that a complete Lie algebroid comorphism from $A$ to $B$ allows us to lift admissible paths and homotopies in $B$ to $A$ (Proposition 9 and 10). These lifting properties, which make complete comorphisms resemble “Serre fibrations,” will be the main ingredients in the proof of Theorem 12 in the next section.

Similar lifting properties in the context of Poisson map integration have already been considered by Caseiro and Fernandes in [1].

4.1. Lie algebroid integration. All the source 1-connected Lie groupoids integrating an integrable Lie algebroid $A \to X$ are isomorphic to the following construction in terms of homotopy classes of paths [4, 7]. Consider the space $\mathcal{P}(A)$ of admissible paths; i.e., the set of paths $g : [0, 1] \to A$, $g(t) = (x(t), \eta(t))$, where $x(t) \in X$ and $\eta(t)$ lies in the fiber of $A$ over $x(t)$, such that

$$\frac{dx(t)}{dt} = \rho(x(t))\eta(t),$$

where $\rho$ is the anchor map of $A$. The source 1-connected Lie groupoid integrating $A$ can be realized as the quotient of $\mathcal{P}(A)$ by a homotopy relation $\sim$ that fixes the endpoints of the base component of the admissible path (see [4, 7]). More precisely, $(x_1(t), \eta_1(t))$ is homotopic to $(x_2(t), \eta_2(t))$ iff there is a family

$$(x_1(t), \eta_1(t)) \xrightarrow{s=0} (x(t, s), \eta(t, s)) \xrightarrow{s=1} (x_2(t), \eta_2(t))$$

of admissible paths parametrized by $s \in [0, 1]$ that satisfies the following condition: There exists a section $\beta$ of $A$ defined along $x(t, s)$ that vanishes for $t = 0, 1$, such that, locally,

$$\frac{\partial x^i(t, s)}{\partial s} = \rho^i_\alpha(x(t, s))\beta^\alpha(t, s),$$

$$\frac{\partial \eta^i(t, s)}{\partial s} = \frac{\partial \beta^i(t, s)}{\partial t} + f^i_{ab}(x(t, s))\beta^a(t, s)\eta^b(t, s),$$

where $\rho^i_\alpha(x) : U \to \mathbb{R}$ and $f^i_{ab}(x) : U \to \mathbb{R}$ are the structure functions of respectively the anchor map and the Lie bracket on the sections of $A$ expressed in terms of a system of trivializing sections $e_a : U \to A|_U$ (where $a$ ranges from 1 to the dimension of the fibers in $A$) over the local patch with coordinates $x^i$.

We denote by $\Sigma(A)$ the quotient of $\mathcal{P}(A)$ by this homotopy relation and by $[g]$ the homotopy class of $g$. Since $A$ is assumed to be integrable, $\Sigma(A)$ is a Lie groupoid over $X$, whose source and target maps $s, t : \Sigma(A) \to X$ are given by the endpoints of the path projection on the base: $s([g]) = x(0)$ and $t([g]) = x(1)$. The groupoid product is given by concatenation of paths $[g][g'] = [gg']$, where $g \in [g]$ and $g' \in [g']$ are two representatives whose ends $t([g]) = s([g'])$ match smoothly, and where

$$(gg')(t) = \begin{cases} 
2g(2t), & 0 \leq t \leq \frac{1}{2}, \\
2g'(2t - 1), & \frac{1}{2} < t \leq 1.
\end{cases}$$
From now on, we will reserve the notation $\Sigma(A) \rightrightarrows X$ for the source 1-connected Lie groupoid integrating $A$ coming from the construction above.

Note that $\Sigma(A)$ exists as a groupoid but not as a manifold if $A$ is not integrable: for non-integrable Lie algebroids, $\Sigma(A)$ can be realized as a stack (see [19]).

4.2. Comorphism integration. Suppose that $A' \to X'$ is a subalgebroid of an integrable Lie algebroid $A \to X$ with integrating 1-connected Lie groupoid $\Sigma(A) \rightrightarrows X$. Then $A'$ is automatically integrable as a Lie algebroid, and we can take its integrating Lie groupoid to be the one obtained by the path construction; namely, $\Sigma(A') \rightrightarrows X'$. An admissible path in $A'$ is by definition also an admissible path in $A$. Moreover, if two admissible paths are homotopic in $A'$, they also are homotopic in $A$. Therefore, we have a natural immersion

$$\iota : \Sigma(A') \to \Sigma(A),$$

which is a groupoid morphism. However, this map is general not an embedding nor is its image a closed submanifold. When the Lie subalgebroid $A'$ is over the same base as $A$, then Moerdijk and Mrčun in [16] gave a necessary and sufficient condition for $\iota$ to be a closed embedding.

The situation is similar for the integration of a comorphism $(\phi, \Phi)$ from a Lie algebroid $A \to X$ to a Lie algebroid $B \to Y$, since a comorphism graph $\gamma(\phi, \Phi)$ is a Lie subalgebroid (over the graph of $\phi$) of the direct product of the Lie algebroids $A$ and $B$. If $A$ and $B$ are integrable, we can thus realize the hypercomorphism between the Lie groupoids $\Sigma(A)$ and $\Sigma(B)$ in terms of the path construction as the groupoid immersion

$$\iota : \Sigma(\gamma(\phi, \Phi)) \to \Sigma(A) \times \Sigma(B).$$

Section 3 gave an explicit example of a comorphism for which $\iota$ is not an embedding and its image is not a closed submanifold.

Let us now describe $\Sigma(\gamma(\phi, \Phi))$ in more explicit terms. It can be realized as the set of homotopy classes $[\gamma]$ of paths $\gamma(t) = (g(t), h(t))$, where $g(t)$ is an admissible path in the Lie algebroid $A \to X$ and $h(t)$ is an admissible path in the Lie algebroid $B \to Y$ of the form

$$g(t) = \left(x(t), \Phi(x(t), \xi(t))\right),$$

$$h(t) = \left(\phi(x(t)), \xi(t)\right).$$

(4.3)  

(4.4)

In other words, $\gamma$ is an admissible path in the Lie algebroid $\gamma(\phi, \Phi) \to \text{gr } \phi$ which satisfies the following equations

$$\dot{x}(t) = \rho_A(x(t))\Phi(x(t), \xi(t)),$$

$$\dot{\phi}(\dot{x}(t)) = \rho_B(\phi(x(t))\xi(t),$$

where $\rho_A$ and $\rho_B$ are, respectively, the anchor maps of $A$ and $B$. The immersion $\iota$ from $\Sigma(\gamma(\phi, \Phi))$ into $\Sigma(A) \times \Sigma(B)$ is the groupoid morphism given
explicitly by
\[(4.5) \quad \iota : \left( [(g, h)] \right) \rightarrow [(g), (h)],\]
where \([(g, h)]\) is the class of admissible paths up to homotopy in \(\gamma_{(\phi, \Phi)}\), while \([(g), (h)]\) is the corresponding pair of admissible paths up to homotopy in \(A\) and \(B\), respectively.

4.3. Homotopy lifting property. In this section, we prove some lifting properties for admissible paths and homotopies via complete comorphisms. Let us start by stating two simple facts concerning complete Lie algebroid sections and comorphisms:

- Let \(s^A_t\) and \(s^B_t\) be (time-dependent) complete sections of Lie algebroids \(A \rightarrow X\) and \(B \rightarrow Y\), respectively. Then, \(\tilde{s}_t = s^A_t \times s^B_t\) is a complete section of the Lie algebroid product \(A \times B \rightarrow X \times Y\).
- For \(i = 1, 2\), let \((\phi_i, \Phi_i)\) be complete comorphisms from \(A_i \rightarrow X_i\) to \(B_i \rightarrow Y_i\). Then \((\phi_1 \times \phi_2, \Phi_1 \times \Phi_2)\) is a complete comorphism from \(A_1 \times A_2 \rightarrow X_1 \times X_2\) to \(B_1 \times B_2 \rightarrow Y_1 \times Y_2\).

**Lemma 8.** Let \((\phi, \Phi)\) be a complete Lie algebroid comorphism from \(A \rightarrow X\) to \(B \rightarrow Y\) and let \(s_t : Y \rightarrow B\) be a complete (time-dependent) section of \(B\). Then
\[(\Phi^\dagger s_t)(x) = \Phi(x, s_t(\phi(x)))\]
is a complete (time-dependent) section of \(A\).

**Proof.** To remove the time-dependency, we can lift \(s_t\) to the Lie Algebroid \(B \times T \mathbb{R} \rightarrow Y \times \mathbb{R}\) by considering the section
\[\tilde{s}(y, t) = s_t(y) + \partial_t,\]
which remains complete but which is now time-independent. The product \(\tilde{\Phi} = (\phi \times \text{id}_{\mathbb{R}}, \Phi \times \text{id}_{T \mathbb{R}})\) is a complete comorphism from \(A \times T \mathbb{R}\) to \(B \times T \mathbb{R}\), since both factors are complete comorphisms. Thus, the lift
\[(\tilde{\Phi}^\dagger \tilde{s})(x, t) = (\Phi^\dagger s_t)(x) + \partial_t\]
is a complete section of \(A \times T \mathbb{R}\), and the induced flow on \(X \times \mathbb{R}\)
\[\tilde{\Psi}_t(x, t) = (\Psi_t(x), t)\]
nexists for all \(x \in X\) and all times \(t \in \mathbb{R}\). Since \(\Psi_t\) is the flow generated by the section \(\tilde{\Phi}^\dagger s_t\), this implies that \(\Phi^\dagger s_t\) is complete. \(\square\)

**Proposition 9.** (Path lifting.) Let \((\phi, \Phi)\) be a complete comorphism from the Lie algebroid \(A \rightarrow X\) to the Lie algebroid \(B \rightarrow Y\), and let \(g(t) = (y(t), \xi(t))\) be an admissible path in \(\mathcal{P}(B)\). Then, through any point \(x \in \phi^{-1}(y(0))\), there exists a smooth curve \(x(t)\) starting at \(x\), which projects onto \(y(t)\) via \(\phi\), and such that
\[\tilde{g}(t) := (x(t), \Phi(x(t), \xi(t)))\]
is an admissible path in \(\mathcal{P}(A)\).
Proof. It is enough to show that we can lift the admissible path \( g \) piecewise in coordinate patches. In a local chart, we can regard the base component \( y(t) \) of a admissible path \( g(t) = (y(t), \xi(t)) \) as being the integral curve of a time-dependent vector field; namely,

\[
X_t(y) = \rho_B(y)(\chi(y)\tilde{\xi}(t)),
\]

where we consider \( s_t(y) := \chi(y)\tilde{\xi}(t) \) to be a local (time-dependent) section of \( B \). In \([4.6]\), \( \chi \) is a cutoff function that vanishes outside a compact containing the image of the curve \( y(t) \) and that is equal to 1 on a smaller compact containing it, and \( \tilde{\xi} \) is a smooth extension of \( \xi \) to \( \mathbb{R} \) that coincides with \( \xi \) on \([0,1]\).

The idea is to pullback \([4.6]\) to a vector field on \( X \) and to obtain the lift of our admissible path as an integral curve of this new vector field.

Because of the cutoff function, \( X_t \) is compactly supported and thus complete. By Lemma 8, we obtain that \( \Phi^\dagger s_t \) is complete. Thus the integral curve \( x(t) \) of \( \rho_A\Phi^\dagger s_t \) starting at the point

\[
x(0) \in \phi^{-1}(y(0)),
\]

exists for all \( t \), and, in particular, for all \( t \in [0,1] \). On this interval, we have that

\[
\dot{x}(t) = \rho_A(x(t))\Phi \left( x(t), \xi(t) \right),
\]

which shows that

\[
\left( x(t), \Phi \left( x(t), \xi(t) \right) \right)
\]

is an admissible path that lifts the one we started with. \( \square \)

Now we can apply Proposition 3 to homotopies

\[
g(t, s) = (y(t, s), \xi(t, s))
\]

between admissible paths in \( \mathcal{P}(B) \). By definition of homotopy, the path \( g_s : t \mapsto g(t, s) \) is an admissible path in \( \mathcal{P}(B) \) for each fixed value \( s \in [0,1] \) of the homotopy parameter. Then, given a complete comorphism \((\phi, \Phi)\) from \( A \) to \( B \) and a starting point \( x \in \phi^{-1}(y(0,0)) \), Proposition 3 gives us a family of admissible paths,

\[
\tilde{g}_s(t) = \left( x(t, s), \Phi \left( x(t, s), \xi(t, s) \right) \right),
\]

in \( \mathcal{P}(A) \) indexed by \( s \in [0,1] \), and such that \( \phi(x(t, s)) = y(t, s) \) for all \( t \) and \( s \).

**Proposition 10.** *(Homotopy lifting.)* The family \( \tilde{g}(t, s) := \tilde{g}_s(t) \) as above is a homotopy between admissible paths in \( \mathcal{P}(A) \).
Proof. Consider the Lie algebroid product \( \tilde{A} := A \times TI \times TJ \) (resp. \( \tilde{B} := B \times TI \times TJ \)). We denote by \( t \) the variable in \( I = [0, 1] \) and by \( s \) the variable in \( J = [0, 1] \). We introduce the following local section of \( \tilde{B} \):
\[
    s_{\xi}(y, t, s) = \xi(t, s) + \partial_t,
\]
\[
    s_{\beta}(y, t, s) = \beta(t, s) + \partial_s,
\]
where \( \xi(t, s) \) is the fiber component of the homotopy \( g(t, s) \) and where \( \beta(t, s) \) is the local expression of the associated section \( \beta_t \), restricted to \( y(t, s) \). A straightforward computation tells us that \([s_{\xi}, s_{\beta}]_A = 0\) since \( g \) is a homotopy. Moreover, for each fixed \( s \) the curve \( t \mapsto (y(t, s), t, s) \) is an integral curve of \( \tilde{\rho}_B s_{\xi} \), while, for each fixed \( t \), the map \( s \mapsto (y(t, s), t, s) \) is an integral curve of \( \tilde{\rho}_B s_{\beta} \), where \( y(t, s) \) is the base component of the homotopy \( g(t, s) \).

We can now lift the local sections \( s_{\xi} \) and \( s_{\beta} \) of \( \tilde{B} \) to local sections \( \tilde{\Phi}^1 s_{\xi} \) and \( \tilde{\Phi}^1 s_{\beta} \) of \( \tilde{A} \) via the comorphism \((\tilde{\phi}, \tilde{\Phi})\) from \( \tilde{A} \) to \( \tilde{B} \) defined by
\[
    \tilde{\phi} = \phi \times \text{id}_I \times \text{id}_J, \quad \tilde{\Phi} = \Phi \times \text{id}_{TI} \times \text{id}_{TJ}.
\]
Because \([s_{\xi}, s_{\beta}]_A = 0\) and because \( \tilde{\Phi} \) and \( \tilde{\rho}_A \) are Lie morphisms, we obtain that
\[
    [\tilde{\Phi}^1 s_{\xi}, \tilde{\Phi}^1 s_{\beta}] = 0 \quad \text{and} \quad [\tilde{\rho}_A \tilde{\Phi}^1 s_{\xi}, \tilde{\rho}_A \tilde{\Phi}^1 s_{\beta}] = 0.
\]
Now consider the family of curves
\[
    \gamma(t, s) := (x(t, s), t, s),
\]
where \( x(t, s) \) is the base component of the lift \( \tilde{g}(t, s) \) in (4.7). A straightforward computation shows that the curve \( \gamma(\cdot, s) : t \mapsto \gamma(t, s) \) is an integral curve of \( \tilde{\rho}_A \tilde{\Phi}^1 s_{\xi} \) for each \( s \in [0, 1] \) (namely, we obtained these curves as lifts of admissible paths in \( \tilde{B} \) for each \( s \), and thus they are admissible paths in \( A \) for each \( s \)). Similarly, a direct computation gives that the curve \( \gamma(0, \cdot) : s \mapsto \gamma(0, s) \) is an integral curve of \( \tilde{\rho}_A \tilde{\Phi}^1 s_{\beta} \) (this relies mostly on the fact that \( \beta_0 = 0 \) and that \( x(0, s) = x \) is constant). Since the vector fields \( \tilde{\rho}_A \tilde{\Phi}^1 s_{\xi} \) and \( \tilde{\rho}_A \tilde{\Phi}^1 s_{\beta} \) commute, the family of integral curves of \( \tilde{\rho}_A \tilde{\Phi}^1 s_{\beta} \) starting at \( \gamma(t, 0) \) for \( t \in [0, 1] \) coincide with the family \( \gamma(t, \cdot) : s \mapsto \gamma(t, s) \), which implies, in particular, that \( x(t, s) \) satisfies equation (4.1). Now the vanishing in (4.8) implies the second homotopy equation (4.2) by direct computation. \( \square \)

Corollary 11. Let \( A \to X \) and \( B \to Y \) be two integrable Lie algebroids, and let \( (\phi, \Phi) \) be a complete comorphism from \( A \) to \( B \). For all \( g \in \mathcal{P}(B) \) with source \( r_B(g) \) in the image of \( \phi \), we have that \( (\tilde{g}, g) \in \mathcal{P}(\gamma(\phi, \Phi)) \), where \( \tilde{g} \) is a lift of \( g \) through \( x \in \phi^{-1}(s_B(g)) \). Moreover, if \( h \sim g \), then \( (\tilde{h}, h) \sim (\tilde{g}, g) \).

4.4. Analogy with Serre fibrations. There is a certain similarity between complete comorphisms and “Serre fibrations” in topology. Namely, a Serre fibration is a continuous map \( \phi : X \to Y \) between topological spaces (more precisely CW-complexes) such that for all \( n \geq 0, f : I^n \to X \) and \( g : I^n \times I \to \)
satisfying $\phi \circ f = g \circ i_n$, where $i_n : I^n \to I^n \times I$ is the inclusion given by $i_n(\vec{t}) = (\vec{t}, 0)$, there exists $\tilde{g}$ that makes the following diagram commute:

When $n = 0$, $I^0 = \{\ast\}$, and we obtain the path lifting property for $\phi$; when $n = 1$, we obtain the homotopy lifting property for homotopies between paths in $Y$.

The analogy comes from the following facts:

- An admissible path in the algebroid $A \to X$ is the same thing as a Lie algebroid morphism from $TI$ to $A$;
- A homotopy between admissible paths is a Lie algebroid morphism from $TI \times TI$ to $A$;
- The tangent map to the inclusion $i_n$ is a Lie algebroid morphism from $TI^n$ to $TI^n \times TI$.

With this in mind, Propositions 9 and 10 can be summarized diagrammatically (for $n = 0, 1$) as follows:

where $\Phi$ is a complete algebroid comorphism from Lie algebroids $A \to X$ to $B \to Y$. For $n = 0$, $g$ is an admissible path, and, for $n = 1$, $g$ is a homotopy between admissible paths.

The problem with the diagram above is that its arrows do not belong to the same category, since it involves morphisms and comorphisms of Lie algebroids. Going beyond a mere analogy would require a category whose objects are the Lie algebroids and whose morphisms comprise both morphisms and comorphisms of Lie algebroids.

5. The integration functor

In [10], Dazord announced, without proof ([10] Thm. 4.1)), that a complete comorphism between integrable Lie algebroids always integrates to a unique
comorphism between the integrating Lie groupoids. We will prove this result here using the path construction, which, together with Proposition 6, yields an improvement of Dazord’s Theorem: namely, that a Lie algebroid comorphism is integrable if and only if it is complete.

Actually, we will show that the classical integration functor for Lie algebras generalizes to integrable Lie algebroids and complete comorphisms:

**Theorem 12.** The path construction \( \Sigma \) is a functor from the category of integrable Lie algebroids and complete comorphisms to the category of source 1-connected Lie groupoids and comorphisms. It is an inverse to the Lie functor \( \text{Lie} \), and, thus, implements an equivalence between these two categories.

As corollary of Theorem 12, Proposition 6 and Corollary 25 (for the uniqueness part), we obtain Dazord’s statement:

**Corollary 13.** (Dazord [10].) Let \( A \to X \) and \( B \to Y \) be two integrable Lie algebroids with source 1-connected integrating Lie groupoids \( G \) and \( H \). Then a Lie algebroid comorphism from \( A \) to \( B \) integrates to a (unique) Lie groupoid comorphism from \( G \) to \( H \) if and only if it is complete.

The rest of this section is devoted to the proof of Theorem 12. In Paragraph 5.1, we show that \( \Sigma \) takes a complete Lie algebroid comorphism to a Lie groupoid comorphism. In Paragraph 5.2, we show that \( \Sigma \) is functorial, and in Paragraph 5.1 we show that it is a homotopy inverse to the Lie functor.

**Remark 14.** One way to prove that a complete Lie algebroid comorphism integrates to a Lie groupoid comorphism would be to adapt the corresponding proof for complete Poisson maps of Caseiro and Fernandes (Prop. 4.8 in [1]) to comorphisms and to show that the resulting embedded subgroupoid is the graph of a Lie groupoid comorphism. We give in Paragraph 5.1 a different proof, which, however, relies also on the same kind of lifting properties as in [1].

5.1. **Embeddability.** Recall that any source 1-connected Lie groupoid integrating a Lie algebroid \( A \to X \) is isomorphic to the Lie groupoid \( \Sigma(A) \) obtained by the path construction. Therefore, in order to prove the first part of the theorem, it is enough to show that the immersion

\[
\iota : \Sigma(\gamma(\phi,\Phi)) \longrightarrow \Sigma(A) \times \Sigma(B),
\]

\[
[(g, h)] \mapsto ([g], [h]),
\]

defined in (4.5) (i.e., the hypercomorphism integrating the comorphism \( (\phi, \Phi) \) from \( A \) to \( B \)) is a closed embedding whose image is the graph of a comorphism \( (\phi, \Psi) \) from \( \Sigma(A) \) to \( \Sigma(B) \), when \( (\phi, \Phi) \) is complete.

We start with a series of lemmas, in which \( A \) and \( B \) will always be integrable, and \( (\phi, \Phi) \) will always be a complete comorphism of Lie algebroids from \( A \) to \( B \).
Lemma 15. The immersion $\iota : \Sigma(\gamma(\phi, \Phi)) \to \Sigma(A) \times \Sigma(B)$ defined in (4.5) is injective. Moreover, we have that

(5.1) $\Sigma_i(\gamma(\phi, \Phi)) \cap (\Sigma(A) \times Y) = \text{gr} \phi,$

where $\Sigma_i(\gamma(\phi, \Phi)) := \iota(\Sigma(\gamma(\phi, \Phi))).$

Proof. Since $\iota$ is also a groupoid morphism, we only need, in order to show injectivity, to check that if $\iota([\gamma])$ is a groupoid unit, then so is $[\gamma]$. For this, we start with a representative of $[\gamma]$, say,

$$\gamma : t \mapsto \left( (x(t), \Phi(x(t), \xi(t))), (\phi(x(t)), \xi(t)) \right).$$

Let us denote by $\gamma_A$ (resp. $\gamma_B$) the component of $\gamma$ in $\mathcal{P}(A)$ (resp. $\mathcal{P}(B)$). Because $\iota$ sends $[\gamma]$ to a unit, there is a homotopy

$$\gamma_B \xleftarrow{t=0} g(t, s) := (y(t, s), \xi(t, s)) \xrightarrow{s=1} (y, 0)$$

between $\gamma_B$ and a constant path. Using Proposition 10, we can lift $g$ to a homotopy of the form

$$\tilde{g}(t, s) := (x(t, s), \Phi(x(t), \xi(t, s))) \xrightarrow{s=0} \gamma_A$$

among the admissible paths in $\mathcal{P}(A)$, such that $\phi(x(t, s)) = y(t, s)$. This homotopy relates $\gamma_A$ to a constant path $(0, x)$, for we have that $\xi(t, 1) = 0$ for all $t \in [0, 1]$. Putting the homotopies for the two components of $\iota([\gamma])$ together, we obtain a homotopy

$$\left( (x(t, s), \Phi(x(t), \xi(t, s))), (\phi(x(t, s)), \xi(t, s)) \right)$$

in $\mathcal{P}(\gamma(\phi, \Phi))$ (see Corollary 11) between $[\gamma]$ and a unit in $\Sigma(\gamma(\phi, \Phi)) \supseteq \text{gr} \phi$.

The very same argument also proves the second part of the statement, since we only needed $[\gamma_B]$ to be a unit in $\Sigma(B) \supseteq Y$ in order to prove that $[\gamma_A, \gamma_B]$ is a unit in $\Sigma(\gamma(\phi, \Phi)) \supseteq \text{gr} \phi$. \[\square\]

Lemma 16. The intersection of $\Sigma_i(\gamma(\phi, \Phi))$ with $r_A^{-1}(x) \times r_B^{-1}(\phi(x))$ is the graph of a map $\psi_x : r_B^{-1}(\phi(x)) \to r_A^{-1}(x)$ for all $x \in A$.

Proof. Suppose that we have two elements

$$([g], [h]), ([g'], [h]) \in \Sigma_i(\gamma(\phi, \Phi)) \cap (r_A^{-1}(x) \times r_B^{-1}(\phi(x))).$$

Consider the corresponding preimages $[(g, h)]$ and $[(g', h)]$ in $\Sigma(\gamma(\phi, \Phi))$ (which are unique, since $\iota$ is injective). Because $\Sigma(\gamma(\phi, \Phi))$ is a groupoid, the inverse $[(g^{-1}, h^{-1})]$ of $[(g, h)]$ is in $\Sigma(\gamma(\phi, \Phi))$, and so is the product $[(g'g^{-1}, hh^{-1})]$. Using Lemma 15 with $\iota([g'g^{-1}, hh^{-1}]) = ([g'g^{-1}], [hh^{-1}]) \in \Sigma_i(\gamma(\phi, \Phi)) \cap (\Sigma(A) \times Y)$, we obtain that $[g'g^{-1}]$ is a unit in $\Sigma(A)$, and thus $[g'] = [g] = : \psi_x([h])$. \[\square\]
Lemma 17. Let \( g \in \mathcal{P}(B) \) be an admissible path, and suppose that we have two lifts \( \tilde{g}_1, \tilde{g}_2 \in \mathcal{P}(A) \) of \( g \), as in Proposition 14 such that \( r_A([\tilde{g}_1]) = r_A([\tilde{g}_2]) \) (i.e., they are lifts of \( g \) through the same point \( x \in X \), which is the source of both paths \( \tilde{g}_1 \) and \( \tilde{g}_2 \)). Then \( [\tilde{g}_1] = [\tilde{g}_2] \).

Proof. Suppose that \( [\tilde{g}_1] \neq [\tilde{g}_2] \). Then both \( ([\tilde{g}_1], g) \) and \( ([\tilde{g}_2], g) \) are admissible paths in \( \mathcal{P}(\gamma(\phi, \Psi)) \) by Corollary 11. Thus, we obtain two different elements \( ([\tilde{g}_1], [g]) \) and \( ([\tilde{g}_2], [g]) \) in \( \Sigma_{\iota}(\gamma(\phi, \Psi)) \), which contradicts Lemma 17.

Since \( r_B \) is a surjective submersion, the fiber product \( X \times_Y \Sigma(B) \) is a closed submanifold of \( \Sigma(A) \times \Sigma(B) \). Now Lemma 16 shows that \( \Sigma_{\iota}(\gamma(\phi, \Psi)) \) is the image of a section \( \sigma \) of the fibration

\[
r_A \times \text{id} : \Sigma(A) \times \Sigma(B) \to X \times \Sigma(B)
\]

over the closed submanifold \( X \times_Y \Sigma(B) \), and where \( \sigma(x, [g]) := (x, \psi_x([g])) \), and thus \( \Sigma_{\iota}(\gamma(\phi, \Psi)) \) is a closed submanifold. We have thus shown that \( \Sigma_{\iota}(\gamma(\phi, \Psi)) \) is the graph of a comorphism \( (\phi, \Psi) \) from \( \Sigma(A) \) to \( \Sigma(B) \), where

\[
\Psi(x, [g]) = \psi_x([g]) = [\tilde{g}]
\]

with \( [\tilde{g}] \) being the unique homotopy class of lifts of \( g \) through \( x \).

5.2. Functoriality. As we explained in Section 4.2 the path construction \( \Sigma \) associates a source 1-connected Lie groupoid \( \Sigma(A) \) with an integrable Lie algebroid \( A \). In the previous paragraph, we showed that \( \Sigma \) associates the comorphism \( \Sigma(\gamma(\phi, \Psi)) \) from \( \Sigma(A) \) to \( \Sigma(B) \) with a complete comorphism from \( A \) to \( B \).

We want to show that \( \Sigma \) is a functor from the category of integrable Lie algebroids and complete comorphisms to the category of source 1-connected Lie groupoids and comorphisms. For this, we need to show that

\[
\Sigma(R_2) \circ \Sigma(R_1) = \Sigma(R_3),
\]

where \( R_1 \) is the graph of a comorphism \( (\phi_1, \Phi_1) \) from \( A \) to \( B \), \( R_2 \) is the graph of a comorphism \( (\phi_2, \Phi_2) \) from \( B \) to \( C \), and \( R_3 \) is the graph of the composition of \( (\phi_1, \Phi_1) \) with \( (\phi_2, \Phi_2) \). The bases of the integrable Lie algebroids \( A, B, \) and \( C \) are, respectively, \( X, Y, \) and \( Z \).

Recall that the composition of comorphisms between Lie algebroids, Lie groupoids, or, more generally, between fibrations \( r_A : A \to X, \) \( r_B : B \to Y \) and \( r_C : C \to Z \) is given by

\[
(\phi_2, \Psi_2) \circ (\phi_1, \Psi_1) = (\phi_2 \circ \phi_1, \Psi_1 \ast \Psi_2),
\]

\[
(\Psi_1 \ast \Psi_2)(x, c) = \Psi_1(x, \Psi_2(\phi_1(x), c)),
\]

for \( x \in X \) and \( c \in r_C^{-1}(\phi_2 \circ \phi_1(x)) \). This composition translates in terms of the comorphism graphs \( R_1 \) and \( R_2 \) into the composition of the underlying binary
relations: i.e., the graph of the comorphism composition is the relation $R_2 \circ R_1$ in $A \times C$ obtained by projecting the image of

$$(R_1 \times R_2) \cap (A \times \Delta_B \times C),$$

where $\Delta_B$ is the diagonal in $B \times B$, to $A \times C$. The fact that these relations come from comorphism graphs guarantees that the result of the composition is a closed submanifold of $A \times C$.

**Remark 18.** There are three ways of looking at a Lie algebroid comorphism from $A$ to $B$: (1) as the pair $(\phi, \Phi)$; (2) as the underlying relation $\gamma(\phi, \psi) \subseteq A \times B$; (3) as the corresponding Lie algebroid $\gamma(\phi, \psi) \Rightarrow \text{gr} \phi$. Similarly, there are three ways of looking at a Lie groupoid comorphism from $G$ to $H$: (1) as the pair $(\phi, \Phi)$; (2) as the underlying relation $R(\phi, \Phi) \subseteq G \times H$; (3) as the Lie groupoid $R(\phi, \Phi) \Rightarrow \text{gr} \phi$.

**Lemma 19.** $\Sigma(R_2) \circ \Sigma(R_1)$ contains $\Sigma(R_2 \circ R_1)$.

**Proof.** Given $[\gamma] \in \Sigma(R_2 \circ R_1)$, we will exhibit an element $[\gamma_1] \times [\gamma_2] \in \Sigma(R_1) \times \Sigma(R_2)$, whose image by the projection

(5.2) $\Sigma(A) \times \Delta_{\Sigma(B)} \times \Sigma(C) \rightarrow \Sigma(A) \times \Sigma(C)$

is precisely $[\gamma]$. Namely, a representative of $[\gamma] \in \Sigma(R_2 \circ R_1)$ is of the form

$$\gamma : t \mapsto (x(t), (\Phi_1 \ast \Phi_2)(x(t), \xi(t)), (\phi_2 \circ \phi_1)(x(t)), \xi(t))$$

for some path $t \mapsto (x(t), \xi(t))$. We set

$$y(t) := \phi_1(x(t)),$$

$$\eta(t) := \Phi_2(y(t), \xi(t)).$$

This gives us two representatives of paths,

$$\gamma_1 = (g_1, h_1) \text{ in } \Sigma(R_1),$$

$$\gamma_2 = (g_2, h_2) \text{ in } \Sigma(R_2),$$

respectively given by

$$\gamma_1 : t \mapsto (x(t), \Phi_1(x(t), \eta(t)), \phi_1(x(t)), \eta(t)), $$

$$\gamma_2 : t \mapsto (y(t), \Phi_2(y(t), \xi(t)), \phi_2(y(t)), \xi(t)).$$

Since $h_1 = g_2$ by definition, we obtain that

$$[\gamma_1] \times [\gamma_2] \in \Sigma(A) \times \Delta_{\Sigma(B)} \times \Sigma(C),$$

and thus $[\gamma_1] \times [\gamma_2]$ projects via (5.2) on the equivalence class of the path

$$t \mapsto (x(t), \Phi_1(x(t), \eta(t)), \phi_2(y(t)), \xi(t)),$$

which we recognize to be precisely $\gamma$ since

$$(\Phi_1 \ast \Phi_2)(x(t), \xi(t)) = \Phi_1(x(t), \Phi_2(\phi_1(x(t)), \xi(t))).$$
Lemma 20. $\Sigma(R_2 \circ R_1)$ contains $\Sigma(R_2) \circ \Sigma(R_1)$. 

Proof. For this, consider 

$$[\gamma] = [(\gamma_A, \gamma_B)] \in \Sigma(R_1),$$ 

$$[\delta] = [(\delta_B, \delta_C)] \in \Sigma(R_2),$$ 

such that 

$$([\gamma], [\delta]) \in \Sigma(A) \times \Delta \Sigma(B) \times \Sigma(C).$$ 

This means that $[\gamma_B]$ and $[\delta_B]$ are in the same homotopy class of paths in $\mathcal{P}(B)$. Thus, there is a homotopy 

$$\gamma_B^{\nu_B} \delta_B, \quad \nu_B(t,s) := (y(t,s), \eta(t,s)),$$

from $\gamma_B$ to $\delta_B$. The homotopy lifting property (Proposition 10) tells us that we can lift $\nu_B$ to a homotopy $\mu_A$ (among the admissible paths in $\mathcal{P}(A)$) of the form 

$$\gamma_A^{\mu_A} \delta_A, \quad \mu_A(t,s) := (x(t,s), \Phi_1(x(t,s), \eta(t,s))),$$

such that 

$$\nu(t,0) = \gamma_A(t),$$ 

$$\phi_1(x(t,s)) = y(t,s),$$

and where we have set $\delta_A := \mu_A(t,1)$. Now putting $\nu_B$ and $\mu_A$ together, we obtain with Corollary 11 the homotopy 

$$(\gamma_A, \gamma_B) \theta (\delta_A, \delta_B), \quad \theta := (\mu_A, \nu_B),$$

among the paths in $\mathcal{P}(R_1)$. Thus, we can take $(\delta_A, \delta_B)$ as a representative of $[\gamma] \in \Sigma(R_1)$. Finally, we see that the representative 

$$([\gamma], [\delta]) := \left(\left(\delta_A, \delta_B\right), \left(\delta_B, \delta_C\right)\right)$$

projects, after reduction, to $[(\delta_A, \delta_C)]$, which belongs to $\Sigma(R_2 \circ R_1)$. \qed

5.3. Equivalence. We now prove that the functor $\Sigma$ is a homotopy inverse to the Lie functor $\text{Lie}$. 

Since, by construction, $\text{Lie}\Sigma(A) = A$ for any integrable Lie algebroid $A$, we have that $\text{Lie} \circ \Sigma$ is the identity functor. We need to show that $\Sigma \circ \text{Lie}$ is also homotopic to the identity functor. 

Given a source 1-connected Lie groupoid $G$, it is well-known that $\Sigma(\text{Lie}(G))$ is isomorphic, as groupoid, to $G$ (see [17] for instance). Moreover for each such $G$, there is a canonical groupoid isomorphism $\alpha_G : \Sigma(\text{Lie}(G)) \rightarrow G$, which is constructed as follows: 

To begin with, consider the monodromy groupoid $\hat{G}$ of $G$, whose elements are end-point-fixing homotopy classes $[\gamma]$ of $G$-paths, that is, paths $\gamma : [0,1] \rightarrow$
INTEGRATION OF LIE ALGEBROID COMORPHISMS

$G$ such that $\gamma(0)$ is a groupoid unit $x$ and $\gamma(t)$ stays in the source-fiber of $x$ (i.e. $r_G(\gamma(t)) = x$). When $G$ is source 1-connected, the map
\[ \text{ev} : \hat{G} \to G : [\gamma] \mapsto \gamma(1) \]
is a groupoid isomorphism. There is also a groupoid isomorphism $D$ from the monodromy groupoid $\hat{G}$ to $\Sigma(\text{Lie}(G))$. Namely, given a $G$-path $\gamma$,
\[ D(\gamma)(t) = T_{G(\gamma(t))} L_{\gamma(t)} \gamma^{-1} \dot{\gamma}(t), \]
where $L_g(h) = gh$ is the groupoid left-translation, is an admissible path in $\text{Lie}(G)$. It turns out that $D$ preserves the homotopy classes of $G$-paths and $A$-paths and defines a groupoid isomorphism with inverse $D^{-1} : \Sigma(\text{Lie}(G)) \to \hat{G}$.

We refer the reader to [7] for details and proofs.

For each source 1-connected groupoid, we can now define the groupoid isomorphism $\alpha_G := \text{ev} \circ D^{-1} : \Sigma(\text{Lie}(G)) \to G$.

Since isomorphisms in $\text{Gpd}^+$ and $\text{Gpd}^-$ coincide, $\alpha_G$ is also a comorphism.

Let us show now that the $\alpha_G$’s are the components of a natural isomorphism between the identity functor and $\Sigma \circ \text{Lie}$; in other words, that, for any Lie groupoid comorphism $(\phi, \Phi)$ from $G$ to $H$, the following diagram commutes:

\[
\begin{array}{ccc}
\Sigma \circ \text{Lie}(G) & \xrightarrow{\alpha_G} & G \\
\downarrow & & \downarrow \\
\Sigma \circ \text{Lie}(\phi, \Phi) & \xrightarrow{\alpha_H} & (\phi, \Phi) \\
\downarrow & & \downarrow \\
\Sigma \circ \text{Lie}(H) & \xrightarrow{\alpha_H} & H
\end{array}
\]

This follows from the following lemmas.

**Lemma 21.** The diagram above commutes if and only if
\[
(\alpha_G \times \alpha_H)(\gamma_{\Sigma \circ \text{Lie}(\phi, \Phi)}) = \gamma_{(\phi, \Phi)},
\]
where $\gamma_{\Sigma \circ \text{Lie}(\phi, \Phi)}$ and $\gamma_{(\phi, \Phi)}$ are the graphs of the corresponding comorphisms.

**Proof.** This comes from the fact that composition of comorphisms is the same as the composition of their underlying graphs as binary relations (i.e. $\gamma_{(\phi_1, \Phi_1)} \circ \gamma_{(\phi_2, \Phi_2)} = \gamma_{(\phi_1, \Phi_1) \circ (\phi_2, \Phi_2)}$). Namely, one checks that for sets $G, H, G', H'$, bijections $\alpha_G : G' \to G$ and $\alpha_H : H' \to H$, and binary relations $R \subset G \times H$ and $R' \subset G' \times H'$, we have $R \circ \text{gr} \alpha_G = \text{gr} \alpha_H \circ R'$ (where the composition is the composition of binary relations) if and only if $(\alpha_G \times \alpha_H)(R') = R$. \qed

**Lemma 22.** Let $G \rightrightarrows X$ and $H \rightrightarrows Y$ be Lie groupoids, with $H$ source 1-connected. Then the graph $\gamma_{(\phi, \Phi)}$ of a comorphism $(\phi, \Phi)$ from $G$ to $H$ (seen as a subgroupoid of $G \times H$) is source 1-connected.
Proof. We need to show that the source fiber \( s^{-1}(x, \phi(x)) \) in \( \gamma_{(\phi, \Phi)} \) is 1-connected for all \( x \in X \). Since \( \gamma_{(\phi, \Phi)} \) is a subgroupoid of \( G \times H \), we have that
\[
s^{-1}(x, \phi(x)) = (s_G \times s_H)^{-1}(x, \phi(x)) \cap \gamma_{(\phi, \Phi)} = \text{gr} \Phi_x.
\]
Because the domain \( s^{-1}_H(x) \) of \( \Phi_x \) is 1-connected by assumption, so is its graph. \( \square \)

Lemma 23. We have that \( \alpha_{G \times H} = \alpha_G \times \alpha_H \), for \( G \) and \( H \) source 1-connected Lie groupoids. Moreover, the restriction of \( \alpha_G \) to a source 1-connected Lie subgroupoid \( H \) coincides with \( \alpha_H \); in other words, the following diagram commutes:

\[
\begin{array}{ccc}
\Sigma \circ \text{Lie}(H) & \xrightarrow{k} & \Sigma \circ \text{Lie}(G) \\
\alpha_H \downarrow & & \downarrow \alpha_G \\
H & \xrightarrow{i} & G
\end{array}
\]

where \( k \) sends a homotopy class \( [\gamma]_H \) of admissible paths in \( \text{Lie}(H) \) to the homotopy class of path \( [\gamma]_G \) in \( \text{Lie}(G) \), and \( i \) is the inclusion of \( G \) in \( H \).

Proof. The first statement follows from the facts that
\[
\begin{align*}
\Sigma \circ \text{Lie}(G \times H) &= \Sigma \circ \text{Lie}(G) \times \Sigma \circ \text{Lie}(H), \\
\widehat{G \times H} &= \hat{G} \times \hat{H}, \\
\text{ev}_{G \times H} &= \text{ev}_G \times \text{ev}_H, \\
D_{G \times H} &= D_G \times D_H.
\end{align*}
\]
As for the second statement, observe first that \( k \) is well-defined, since an admissible path in \( \text{Lie}(H) \) is also an admissible path in \( \text{Lie}(G) \), and homotopic \( \text{Lie}(H) \)-paths are also homotopic as \( \text{Lie}(G) \)-paths (since \( \text{Lie}(H) \)-homotopies are also \( \text{Lie}(G) \)-homotopies). Moreover, an admissible \( \text{Lie}(H) \)-path \( \gamma \) integrates to a \( H \)-path, which, considered as a \( G \)-path, is the same as the one \( \gamma \) integrates to when considered as a \( \text{Lie}(G) \)-path. We can then conclude by chasing in the diagram above, starting with the representative \( \gamma \). \( \square \)

Lemma 24. The \( \alpha \)'s defined above are the components of a natural transformation.

Proof. By Lemma 21 we only need to show that the Lie groupoid comorphisms \( (\alpha_G \times \alpha_H)(\gamma_{\Sigma \circ \text{Lie}(\phi, \Phi)}) \) and \( \gamma_{(\phi, \Phi)} \) coincide. Since \( \gamma_{(\phi, \Phi)} \) is a source 1-connected groupoid by Lemma 22 we have that \( \alpha_{(\phi, \Phi)} \) is an isomorphism from \( \gamma_{\Sigma \circ \text{Lie}(\phi, \Phi)} \) to \( \gamma_{(\phi, \Phi)} \). From Lemma 23 we can conclude that the restriction of \( \alpha_G \times \alpha_H = \alpha_{G \times H} \) to the subgroupoid \( \gamma_{\Sigma \circ \text{Lie}(\phi, \Phi)} \) coincides with \( \alpha_{(\phi, \Phi)} \), whose image is exactly \( \gamma_{(\phi, \Phi)} \). \( \square \)
Consequently, $\Sigma$ is a homotopy inverse to the Lie functor, implementing thus an equivalence of categories. As corollary, we have that

**Corollary 25.** The Lie functor is faithful. In other words, the Lie groupoid comorphism integrating a complete Lie algebroid comorphism is unique.

### 6. The Symplectization Functor

There is an immediate application of Theorem 12 in Poisson geometry. Namely, this theorem implies, as we will see below, that the integration of Poisson manifolds by symplectic groupoids using the path construction is an actual functor from the category of integrable Poisson manifolds and complete Poisson maps to the category $\mathbf{SGpd}$ of source 1-connected symplectic groupoids and symplectic comorphisms.

A symplectic comorphism from symplectic groupoids $G \rightrightarrows X \rightrightarrows Y$ is a comorphism $(\phi, \Phi)$ whose underlying graph $\gamma(\phi, \Phi)$ is a canonical relation from $G$ to $H$. In contrast with general canonical relations, symplectic comorphisms always compose well (because they are comorphisms in the first place), and thus form a category. Observe that the graph $\gamma(\phi, \Phi)$ of a symplectic comorphism is a lagrangian subgroupoid of $G \times H$.

A complete Poisson map $\phi$ from $X$ to $Y$ is a Poisson map with the property that the hamiltonian vector field $\xi_{\phi^* f}$ on $X$ with hamiltonian $\phi^* f$ is complete if the hamiltonian vector field $\xi_f$ on $Y$ with hamiltonian $f \in C^\infty(Y)$ is complete.

Fernandes in [9] studied constructions in Poisson geometry involving the integration of Poisson manifolds seen as a functor, which he called the “symplectization functor.” However, in [9] the domain of this functor comprises all Poisson maps and its range has for morphisms from $G$ to $H$ all the lagrangian subgroupoids of $G \times H$, instead of only those that are graphs of symplectic comorphisms. This choice has as a consequence that the range category is not an honest category (the compositions are not always well-defined). Moreover, if we drop the completeness condition, there are Poisson maps that do not integrate to symplectic comorphisms as illustrated in the example below. Hence, the symplectization functor is not a true functor with this choice of domain and range.

**Example 26.** Consider the non-complete and non-integrable Lie algebroid comorphism $(\phi, \Phi)$ from $TX$ to $TY$ of Section 3. Its dual $\Phi^*$ is a non-complete Poisson map from cotangent bundles $T^*X$ to $T^*Y$ endowed with their canonical Poisson structure. Let us see that $\Phi^*$ is also non-integrable. Since the graph $\text{gr} \phi^*$ is a coisotropic submanifold of the symplectic manifold $T^*X \times T^*Y$ (with symplectic form $\Omega = -\omega + \omega$), the (immersed) lagrangian subgroupoid integrating $\Phi^*$ can be identified with the leafwise fundamental groupoid of the characteristic foliation $\mathcal{F}$ of $\text{gr} \phi^*$ (whose associated distribution we denote by $\Delta$). For two vectors in the tangent space to $\text{gr} \phi^*$ (which we identify with
vectors \( \nu = v \oplus \theta_v \) in \( TT^* X \simeq TX \oplus T^* X \), we have that
\[
\Omega(\nu, w) = -\langle (\text{id} - \Phi \circ T\phi)v, \theta_w \rangle + \langle (\text{id} - \Phi \circ T\phi)w, \theta_v \rangle.
\]
From this last equation, we see that \( \Omega(\nu, w) = 0 \) for all vectors \( \nu \) tangent to \( \text{gr } \phi^* \) iff \( w \in \text{Im } \Phi \oplus (\text{Ker } T\phi)^0 \), where \( \text{Im } \Phi \) is the distribution of the foliation given by the flat Ehresmann connection associated with \((\phi, \Phi)\) and \((\text{Ker } T\phi)^0\) is the annihilator of vertical distribution associated with the submersion \( \phi \). Hence,
\[
\tilde\Delta = \text{Im } \Phi \oplus (\text{Ker } T\phi)^0,
\]
and the leafwise fundamental groupoid of \( \tilde{\mathcal{F}} \) may be parametrized by \( \tilde{\Gamma} = T^* \Gamma \), where
\[
\Gamma = (\mathbb{R}^+ \times S^1) \times (\mathbb{R}^+ \times \mathbb{R}) \times \mathbb{C} \times (-1, 1)
\]
parametrizes the leafwise fundamental groupoid of the Ehresmann connection on \( X \) as described in Section 3. The element
\[
\tilde{\gamma} = (r, \theta, r', \tau, z, h, \xi_r, \xi_\theta, \xi_r', \xi_\tau, \xi_z, \xi_h)
\]
of \( \tilde{\Gamma} \) corresponds to the homotopy class of the leafwise path
\[
t \mapsto \left( r + (r' - r)t, \theta + \tau t, e^{\text{i} \nu(h)t}z, h, \xi_r + (\xi_r' - \xi_r)t, \xi_\theta + \xi_\tau t, \xi_z, \xi_h \right),
\]
with \( 0 \leq t \leq 1 \). We see that we obtain the same non-trivial self-intersections for the immersion
\[
\tilde{\Gamma} \to \mathcal{T}^* X \times T^* X \times \mathcal{T}^* Y \times T^* Y
\]
at \( z = 0 \) for the exact same reasons as in Section 3.

As with Lie algebroids, there is a Lie functor \( \text{Lie} \) from \( \text{SGpd} \) to the category of Poisson manifolds and Poisson maps. It takes a symplectic groupoid \( G \rightrightarrows X \) to the Poisson manifold \( (X, \Pi_X) \), where \( \Pi_X \) is the unique Poisson structure turning \( r_G \) into a Poisson map (and \( l_G \) into an anti-Poisson map). Since the graph of a symplectic comorphism \((\phi, \Phi)\) from \( G \rightrightarrows X \) to \( H \rightrightarrows Y \) is a lagrangian subgroupoid \( \gamma_{(\phi, \Phi)} \rightrightarrows \text{gr } \phi \), this implies that the graph of \( \phi \) is a coisotropic submanifold (see [3]), and, hence, that \( \phi \) is a Poisson map. The Lie functor on morphisms is thus defined as \( \text{Lie}(\phi, \Phi) = \phi \).

The path construction can also be extended in a functorial way to the Poisson realm. Namely, integrating a Poisson manifold \( X \) is equivalent to integrating its associated Lie algebroid \( T^* X \rightrightarrows X \), whose bracket on sections is the Koszul bracket and whose anchor map is the map \( \Pi^\sharp : T^* X \to TX \) associated with the Poisson bivector field \( \Pi \in \Gamma(\wedge^2 TX) \). The path construction applied to this Lie algebroid yields a symplectic groupoid \( \Sigma(T^* X) \rightrightarrows X \) (when the Poisson manifold is integrable as seen in [4]), that is, a groupoid whose total space is symplectic and whose multiplication graph is a lagrangian subgroupoid of \( \Sigma(T^* X) \times \Sigma(T^* X) \times \Sigma(T^* X) \). (The bar on a Poisson manifold denotes the same Poisson manifold but with opposite Poisson structure.)
To extend the path construction to Poisson maps, we need the following proposition, which can already be (partly) found in [12]:

**Proposition 27.** Let \((X, \Pi_X)\) and \((Y, \Pi_Y)\) be two Poisson manifolds. A smooth map \(\phi : X \to Y\) is a Poisson map if and only if its cotangent map \(T^s\phi\) is a Lie algebroid comorphism from \(T^sX\) to \(T^sY\) (with the Lie algebroid structure described above). Moreover, \(\phi\) is complete if and only if \(T^s\phi\) is.

**Proof.** \(T^s\phi\) is a comorphism if and only if its dual, the tangent map \(\phi^*\) from \(TX\) to \(TY\), is a Poisson map with respect to the Poisson structure on \(TX\) and \(TY\) inherited from being duals of Lie algebroids. Thus we only need to show that \(\phi\) is Poisson if and only if \(T\phi\) is. Now a smooth map between two Poisson manifolds is Poisson if and only if its graph is a coisotropic submanifold of the product of the two Poisson manifolds. Hence, the problem reduces to showing that a submanifold \(C\) of a Poisson manifold \(X\) is coisotropic if and only if \(T\phi\) is coisotropic in \(TX\).

Recall that the Poisson structure on \(TX\) can be described locally in terms of the matrix

\[
\Pi_X(x,v) = \begin{pmatrix}
0 & \Pi_X(x) \\
-\Pi_X(x) & \partial_k \Pi_X(x)v^k \\
\end{pmatrix}
\]

and that we can identify a vector in \(T_{(x,v)}TC\) with \(\delta x \oplus \delta v \in T_xC \oplus T_vC\). This further gives the identification of \(N^*_X TC\) with \(N^*_x C \oplus N^*_vC\). Now \(TC\) is coisotropic iff for all \(\theta \oplus \nu \in N^*_X TC\), we have that

\[
\Pi_X(x,v)(\theta \oplus \nu) = \Pi_X(x)\eta \oplus (-\Pi_X(x)\eta + \partial_k \Pi_X(x)v^k \eta) \in T_xC \oplus T_vC,
\]

which is equivalent to \(C\) being coisotropic, since \(\partial_k \Pi_X(x)v^k \eta\) is always in \(T_vC\) provided that \(C\) is coisotropic (to see this, consider the derivative at 0 of the curve \((x(t), \Pi_X(x(t))\eta)\) in \(TC\) such that \(x(0) = x, \dot{x}(0) = v, \eta\) is a section of \(N^*C\)).

This shows that \(\phi\) is Poisson if and only if \(T^s\phi\) is a Lie algebroid comorphism. Let us check now that \(\phi\) is complete whenever \(T^s\phi\) is.

First of all, a direct computation shows that the hamiltonian vector field \(\xi_{\phi^*f}\) where \(f \in C^\infty(Y)\) coincides with \(\Pi_X(T^s\phi)^d f\). Moreover, by definition, \(\xi_f\) is complete if and only if the section \(df\) is complete.

Suppose now that the comorphism \((\phi, T^s\phi)\) is complete. Take a complete hamiltonian vector field \(\xi_f\). Then \((T^s\phi)^d f\) is complete (since \(df\) is complete) which implies thus that \(\xi_{\phi^*f}\) is also complete. Therefore, the Poisson map \(\phi\) is complete.

Conversely, suppose that \(\phi\) is complete and let \(s \in \Gamma(B)\) be a complete section. We need to show that the integral curve of \((T^s\phi)^d s\) through any \(x \in X\) exists for all times. For this, consider the integral curve \(y(t)\) of \(\Pi_X^s\) passing through \(y = \phi(x)\) at time \(t_0\). Choose a partition \(\mathbb{R} = \bigcup_{i \in \mathbb{Z}} [t_i, t_{i+1}]\) such that there exist a family of open subsets \(U_i\) and compact subsets \(K_i\) such that \([t_i, t_{i+1}] \subset K_i \subset U_i\) and the one-form \(s\) is exact on the \(U_i\)’s (i.e.
s_{U_i} = df_i for some smooth function f_i on U_i). For each i ∈ Z, choose further a cut-off function χ_i that is 1 on K_i and zero outside of U_i. Since the function ˜f_i := χ_if_i has compact support, its hamiltonian vector field is complete, and thus ξ_φ∗ ˜f_i = Π^2_X(T^*φ)^†d ˜f_i is also complete, because φ is complete. We can now construct the integral curve of Π^♯X(T^∗φ)^†d ˜f_i for all times by starting at x and following the flow of Π^♯X(T^∗φ)^†d ˜f_i (which exists for all times) between t_i and t_{i+1} for each i ∈ Z.

□

The graph of a Poisson map φ from X to Y is a coisotropic submanifold of the Poisson manifold product X × Y. Thus, the conormal bundle N∗gr φ to this graph is a subalgebroid of the algebroid product T^∗X × T^∗Y. Proposition 27 tells us that this conormal bundle is actually the graph of the Lie algebroid comorphism (φ, T^∗φ) from T^∗X to T^∗Y. Applying the the path construction to this comorphism yields a hypercomorphism

ι : Σ(N∗gr φ) → Σ(T^∗X) × Σ(T^∗Y)

between the integrating symplectic groupoids, which happens to be in general only a lagrangian immersion (see [3] for instance).

Using Theorem 12 and Proposition 27, we obtain that, for a complete Poisson map, the lagrangian immersion ι is a closed lagrangian embedding, and its image, which we denote by Σ(φ), is a closed lagrangian submanifold of Σ(T^∗X) × Σ(T^∗Y). In other words, for complete Poisson maps, Σ(φ) is, at the same time, a canonical relation from Σ(T^∗X) to Σ(T^∗Y), a lagrangian subgroupoid over the graph of φ, and a comorphism from Σ(T^∗X) to Σ(T^∗Y).

In complete analogy with the Lie algebroid case, we can summarize the discussion above by the following statements, some of which can already be found in [1, 10, 20]:

**Proposition 28.** (Zakrzewski [20]) Let G and H be symplectic groupoids over X and Y respectively, and let (φ, Φ) be a symplectic comorphism from G to H. Then φ = Lie(φ, Φ) is a complete Poisson map from X to Y.

**Proof.** The lagrangian subgroupoid γ(φ, Φ) ⇒ gr φ integrates the coisotropic submanifold gr φ, and, thus, integrates the corresponding Lie subalgebroid N∗gr φ (see [3] for instance), which is nothing but the graph of the comorphism T^∗φ from T^∗X to T^∗Y. By Proposition 6 we have then that T^∗φ is complete because integrable, and, hence, that φ is complete by Proposition 27.

□

**Theorem 29.** The path construction Σ is a functor from the category of integrable Poisson manifolds and complete Poisson maps to the category of source 1-connected symplectic groupoids and symplectic comorphisms. It is an inverse to the Lie functor Lie, and, thus, implements an equivalence between these two categories.

**Corollary 30.** (Caseiro-Fernandes [1], Dazord [10], Zakrzewski [20]) Let X and Y be two integrable Poisson manifolds with source 1-connected integrating
symplectic groupoids $G$ and $H$. Then a Poisson map $\phi$ from $X$ to $Y$ integrates to a (unique) symplectic comorphism $(\phi, \Phi)$ from $G$ to $H$ if and only if it is complete.

Theorem [9] provides a rigorous foundation for constructions in Poisson geometry involving $\Sigma$ in the spirit of Fernandes in [9] where $\Sigma$ (which is called the “symplectization functor”) is only considered heuristically.

Remark 31. A weaker version of Corollary [30] was already stated without proof by Dazord in [10], where only the implication from complete to integrable was considered. Recently, Caseiro and Fernandes in [11] proved that the object integrating a complete Poisson map from integrable Poisson manifolds $X$ to $Y$ is an embedded lagrangian subgroupoid of the symplectic groupoid product $\Sigma(X) \times \Sigma(Y)$, using the path construction and similar lifting properties as described in Section 4.3. However, one can find versions and proofs of both this Corollary and Proposition [28] in Zakrzewski’s paper [20], which was written even before the notion of comorphisms was formally introduced by Higgins and Mackenzie in [12]. In [20], Zakrzewski integrates complete Poisson maps not to symplectic comorphisms but to what he called “morphisms of $S^*$-algebras,” which are defined as special canonical relations satisfying certain algebraic relations. One can shows that that Zakrzewski’s morphisms of $S^*$-algebras are nothing but symplectic comorphisms. His proof relies mostly on the method of characteristics for coisotropic submanifolds.
