IntEx: A Syntactic Role Driven Protein-Protein Interaction Extractor for Bio-Medical Text

Syed Toufeeq Ahmed, Deepthi Chidambaram, Hasan Davulcu, Chitta Baral.
Department of Computer Science and Engineering, ASU, Tempe, AZ 85287

ABSTRACT
In this paper, we present a fully automated extraction system, named IntEx, to identify gene and protein interactions in biomedical text. Our approach is based on first splitting complex sentences into simple clausal structures made up of syntactic roles. Then, tagging biological entities with the help of biomedical and linguistic ontologies. Finally, extracting complete interactions by analyzing the matching contents of syntactic roles and their linguistically significant combinations. Our extraction system handles complex sentences and extracts multiple interactions specified in a sentence. Experimental evaluations with two other state of the art extraction systems indicate that the IntEx system achieves better performance without the labor intensive pattern engineering requirement.

1 INTRODUCTION
Genomic research in the last decade has resulted in the production of a large amount of data in the form of micro-array experiments, sequence information and publications discussing the discoveries. The data generated by these experiments is highly connected; the results from sequence analysis and micro-arrays depend on functional information and signal transduction pathways cited in peer-reviewed publications for evidence. Though scientists in the field are aided by many online databases of biochemical interactions, currently a majority of these are curated labor intensively by domain experts. Information extraction from text has therefore been pursued actively as an attempt to extract knowledge from published material and to speed up the curation process significantly.

In the biomedical context, the first step towards information extraction is to recognize the names of proteins (Fukuda, Tsunoda et al. 1998), genes, drugs and other molecules. The next step is to recognize interaction events between such entities (Blaschke, Andrade et al. 1999; Blaschke, Andrade et al. 1999; Hunter 2000; Thomas, Milward et al. 2000; Thomas, Rajah et al. 2000; Ono, Hishigaki et al. 2001; Hahn and Romacker 2002) and then to finally recognize the relationship between interaction events. However, several issues make extracting such interactions and relationships difficult since (Seymore, McCallum et al.) (i) the task involves free text – hence there are many ways of stating the same fact (ii) the genre of text is not grammatically simple (iii) the text includes a lot of technical terminology unfamiliar to existing natural language processing systems (iv) information may need to be combined across several sentences, and (v) there are many sentences from which nothing should be extracted.

In this paper, we present a fully automated extraction approach to identify gene and protein interactions in natural language text with the help of biomedical and linguistic ontologies. Our approach works in three main stages:
- **Complex Sentence Processor (CSP):** First, is splitting complex sentences into simple clausal structures made up of syntactic roles.
- **Tagging:** Then, tagging biological entities with the help of biomedical and linguistic ontologies.
- **Interaction Extractor:** Finally, extracting complete interactions by analyzing the matching contents of syntactic roles and their linguistically significant combinations.

The novel aspects of our system are its abilities to handle complex sentence structures using the Complex Sentence Processor (CSP) and to extract multiple and nested interactions specified in a sentence using the Interaction Extractor. Our approach is based on identification of syntactic roles, such as subject, objects, verb and modifiers, by using the word dependencies. We have used a dependency based English grammar parser, the Link Grammar (Sleator and Temperley 1993), to identify the roles. Syntactic roles are utilized to transform complex sentences into their multiple clauses each containing a single event. This clausal structure enables us to engineer an automated algorithm for the extraction of events thus overcoming the burden of labor intensive pattern engineering for complex and compound sentences. Our pronoun resolution system assists Interaction Extractor in identifying interactions spread across multiple sentences using pronominal references. We performed comparative experimental evaluations with two state of the art systems. Our experimental results show that the IntEx system presented here achieves better performance without the labor intensive rule engineering step which is required for these state of the art systems.
The rest of the paper is organized as follows. In Section 2 we survey the related work. In Section 3 we present an architectural overview of the IntEx system. Sections 4 and 5 explain and illustrate the individual modules of the IntEx system. A detailed evaluation of our system with the BioRAT (Corney, Buxton et al. 2004) and GeneWays (Rzhetsky, Iossifov et al. 2004) is presented in Section 6. Section 7 concludes the paper.

2 RELATED WORK

Information extraction is the extraction of salient facts about pre-specified types of events, entities (Bunescu, Ge et al. 2003) or relationships from free text. Information extraction from free-text utilizes shallow-parsing techniques (Daelemans, Buchholz et al. 1999), Parts-of-Speech tagging (Brill 1992), noun and verb phrase chunking (Mikheev and Finch 1997), verb subject and object relationships (Daelemans, Buchholz et al. 1999), and learned (Califf and Mooney 1998; Craven and Kumlein 1999; Seymore, McCallum et al. 1999) or hand-built patterns to automate the creation of specialized databases.

Manual pattern engineering approaches employ shallow parsing with patterns to extract the interactions. In the (Ono, Hishigaki et al. 2001) system, sentences are first tagged using a dictionary based protein name identifier and then processed by a module which extracts interactions directly from complex and compound sentences using regular expressions based on part of speech tags. The SUISEKI system of Blaschke (Blaschke, Andrade et al. 1999) also uses regular expressions, with probabilities that reflect the experimental accuracy of each pattern to extract interactions into predefined frame structures. GENIES (Friedman, Kra et al. 2001) utilizes a grammar based NLP engine for information extraction. Recently, it has been extended as GeneWays (Rzhetsky, Iossifov et al. 2004), which also provides a Web interface that allows users to search and submit papers of interest for analysis. The BioRAT system (Corney, Buxton et al. 2004) uses manually engineered templates that combine lexical and semantic information to identify protein interactions. The GeneScene system (Leroy, Chen et al. 2003) extracts interactions using frequent preposition-based templates. Grammar engineering approaches, on the other hand use manually generated specialized grammar rules (Rinaldi, Schneider et al. 2004) that perform a deep parse of the sentences. Temkin (Temkin and Gilder 2003) addresses the problem of extracting protein interactions by using an extendable but manually built Context Free Grammar (CFG) that is designed specifically for parsing biological text. The PathwayAssist system uses an NLP system, MedScan (Novichkova, Egorov et al. 2003), for the biomedical domain that tags the entities in text and produces a semantic tree. Slot filler type rules are engineered based on the semantic tree representation to extract relationships from text. Recently, extraction systems have also used link grammar (Grinberg, Lafferty et al. 1995) to identify interactions between proteins (Ding, Berleant et al. 2003). Their approach relies on various linkage paths between named entities such as gene and protein names. Such manual pattern engineering approaches for information extraction are very hard to scale up large document collections since they require labor-intensive and skill-dependent pattern engineering.

Machine learning approaches have also been used to learn extraction rules from user tagged training data. These approaches represent the rules learnt in various formats.
such as decision trees (Chiang, Yu et al. 2004) or grammar rules (Phuong, Lee et al. 2003). Craven et al (Craven and Kumlien 1999) explored an automatic rule-learning approach that uses a combination of FOIL (Quinlan 1990) and Naïve Bayes Classifier to learn extraction rules.

3 SYSTEM ARCHITECTURE

The sentences in English are classified as either simple, complex, compound or complex-compound based on the number and types of clauses present in them. Our extraction system resolves the complex, compound and complex-compound sentence structures (collectively referred to as complex sentence structures in this document) into simple sentence clauses which contain a subject and a predicate. These simple sentence clauses are then processed to obtain the interactions between proteins. The architecture of the IntEx system is shown in Figure 1, and the following Sections 4 and 5 explain the workings of various important modules.

4 COMPLEX SENTENCE PROCESSING

4.1 Pronoun Resolution

Interactions are often specified through pronominal references to entities in the discourse, or through coreferences where, a number of phrases are used to refer to the same entity. Hence, a complete approach to extracting information from text should also take into account the resolution of these references. References to entities are generally categorized as co-references or anaphora and has been investigated using various approaches (Castaño, Zhang et al. 2002). IntEx anaphora resolution subsystem currently focuses on third person pronouns and reflexives since the first and second person pronouns are frequently used to refer to the authors of the papers.

Our pronoun resolution system uses a heuristic approach to identify the noun phrases referred by the pronouns in a sentence. The heuristic is based on the number of the pronoun (singular or plural) and the proximity of the noun phrase. The first noun phrase that matches the number of the pronoun is considered as the referred phrase.

4.2 Entity Tagger

The entity tagging module marks the names of genes, and proteins in text. The process of tagging is a combination of dictionary look up and heuristics. Regular expressions are also used to mark the names that do not have a match in the dictionaries. The protein name dictionaries for the entity tagger are derived from various biological sources such as UMLS1, Gene Ontology2 and Locuslink3 database.

4.3 Preprocessor

The tagged sentences need to be pre-processed to eliminate some syntactic constructs, such as parenthesized nouns and domain specific terminology that cause the Link Grammar Parser to produce an incorrect output. This problem is overcome by replacing such elements with formats that is recognizable by the parser.

4.4 Link Grammar and the Link grammar parser

Link grammar (LG) introduced by Sleator and Temperley (Sleator and Temperley 1991) is a dependency based grammatical system. The basic idea of link grammar is to connect pairs of words in a sentence with various syntactically significant links. The LG consists of set of words, each of which has various alternative linking requirements. A linking requirement can be seen as a block with connectors above each word. A connector is satisfied by matching it with compatible connector. Fig.2 below shows how linking requirements can be satisfied to produce a parse for the example sentence "The dog chased a cat".

![Figure 2: Link grammar representation of a sentence](image)

In the above example the link between ‘dog’ and ‘chased’ is ‘S’ (‘S’ links Subject-noun to verbs), the link between ‘chased’ and ‘cat’ is ‘O’ (‘O’ links verbs to direct or indirect Objects) and the link between ‘the’ and ‘dog’ is ‘D’ (‘D’ links determiners to nouns).

The LG parser is well-suited for our purpose since it accurately produces the linkage and the linkage can be interpreted with linguistically sound rules to extract the major syntactic roles like subjects, objects and their modifiers in a any sentence. Even though LG has no explicit notion of constituents or categories (Sleator and Temper

---

1 http://www.nlm.nih.gov/research/umls/
2 http://www.geneontology.org/
3 http://www.ncbi.nlm.nih.gov/LocusLink/
ley 1993), they emerge as contiguous connected collection of words attached to rest of sentence by a particular type of link, like in the above example 'the dog' and 'a cat' (connected with links 'S' and 'O' respectively). Our algorithms utilize this property of LG where certain link types allow us to extract the constituents of sentence irrespective of the tense. The LG parser’s ability to detect multiple verbs and their constituent linkage in a complex sentence makes it better suited for our approach while resolving complex sentences into multiple clauses. The LG parsers’ dictionary can also be easily enhanced to produce better parses for biomedical text (Szolovits 2003).

4.5 Complex Sentence Processor Algorithm
The complex sentence processor (CSP) component splits the complex sentences into a collection of simple sentence clauses which contain a subject and a predicate. The complex sentence processor follows a verb-based approach to extract the simple clauses. A sentence is identified to be complex it contains more than one verb. A simple sentence is identified to be one with a subject, a verb, objects and modifying phrases. The following schema is used as the format to represent simple clauses:

Subject | Verb | Object | Modifying phrases to the verb

The modifying phrases to the verb can be adverbial, prepositional or adjectival phrases. The components can be a single word or multi-word phrases. Each of the components, once identified is expanded to include multi-word phrases. The link grammar parser links a single word as the subject or the object of a verb. These words are expanded to noun phrases by following the links to add determiners, adjectives and prepositional phrases attached to the words. Hence subjects like 'The kinase activity of C-abl' can also be extracted. The algorithm for complex sentence processing is illustrated by the example in Figure 5.
The example in Fig. 3 illustrates the steps involved in complex sentence processing. The complex sentence processor performs well in identifying the simple sentence when correct parse of sentence is obtained.

5 INTERACTION EXTRACTION

Interaction Extractor (IE) extracts interactions from simple sentence clauses produced by the complex sentence processor. The highly technical terminology and the complex grammatical constructs that are present in the biomedical abstracts make the extraction task difficult. Even a simple sentence with a single verb can contain multiple and/or nested interactions. That’s why our IE system is based on a deep parse tree structure presented by the LG and it considers a thorough case based analysis of contents of various syntactic roles of the sentence like its subject (S), verb (V), object (O) and modifying phrases (MP) as well as their linguistically significant combinations like S-V-O, S-O, S-V-MP or S-MP for extracting interactions (See Fig. 4).

5.1 Role Type Matcher

For each syntactic constituent of the sentence, the role matcher identifies the type of each role as explained in the following Table 1.

| Role Type | Description |
|-----------|-------------|
| Elementary | If the role contains a Protein name or an interaction word. |
| Partial | If the role has a Protein name and an interaction word. |
| Complete | If the role has at least two Protein names and an interaction word. |

5.2 Interaction Word Tagger

The words that match a biologically significant action between two gene/protein names are labeled as ‘interaction words’. Our gazetteer for interaction words is derived from UMLS and WordNet. Porter Stemmer (Porter 1997) was also used for stemming such words before matching.

5.3 Interaction Extractor (IE)

IntEx interaction extractor works as follows. First, the linkage provided by the Link Grammar parser and linguistic rules encoded by the Role Matcher are used to identify the syntactic roles of each sentence clause. Next the interactions words are tagged. IE identifies the main verb of the sentence and from various linguistically significant combinations of different syntactic roles it extracts the protein-protein interactions.

Consider the example shown in Fig. 3, for the third sentence, the role types of the subject and the modifying phrase are identified and both are typed as ‘Elementary’.

---

4 [http://www.cogsci.princeton.edu/~wn/](http://www.cogsci.princeton.edu/~wn/)
according to Table 1. Since the main verb is an interaction word, IE uses the S-M combination role of Figure 4 with the main verb to find and extract the following complete interaction.

{‘The SAC 6 gene Protein’, ‘colocalizes’, ‘actin’}.

Through a detailed case-based analysis of the types of syntactic roles and their linguistically significant combinations (Figure 4), the IE component identifies and extracts the protein/protein interaction information from all complete role types of the sentence.

5.4 Preposition-based patterns

To extract additional context information, such as the location or species, about the interactions specified in the ‘complete’ role types, we have used a set of preposition-based rules for different preposition combinations such as of-by, from-to etc.

For example, in the sentence “The kinase phosphorylation of pRb by c-Abl in the gland could inhibit ku70”, the subject role is “The kinase phosphorylation of pRb by c-Abl in the gland”. Since the subject has at least two protein names and an interaction word it is ‘complete’. By using the of-by pattern (…<Interaction-Word (action)>... of ...<theme>...by ...<agent>...) and the IE is able to extract the correct interaction {c-Abl, phosphorylation, pRb} from the subject alone. By interpreting the ( … in <location>) pattern IE can also extract the location information about the complete interactions.

6 EVALUATION & DISCUSSION

We have evaluated the performance of our system with two state of the art systems - BioRAT (Corney, Buxton et al. 2004) and GeneWays (Rzhetsky, Iossifov et al. 2004).

Blaschke and Valencia (Valencia 2001) recommend DIP (Xenarios, Rice et al. 2000) dataset as a benchmark for evaluating biomedical Information Extraction systems.

The first evaluation for IntEx system was performed on the same dataset that was used for the BioRAT evaluation. For BioRAT evaluation, authors identified 389 interactions from the DIP database such that both proteins participating in the interaction had SwissProt entries. These interactions correspond to 229 abstracts from the PubMed. The BioRAT system was evaluated using these 229 abstracts. The interactions extracted by the system were then manually examined by a domain expert for precision and recall. Precision is a measure of correctness of the system, and is calculated as the ratio of true positives to the sum of true positives and false positives. The sensitivity of the system is given by the recall measure, calculated as the ratio of true positives to the sum of true positives and false negatives.

We have also limited our protein name dictionary to the SwissProt entries. Tables 2 and 3 present the evaluation results as compared with the BioRAT system.

| Results  | IntEx | BioRAT |
|----------|-------|--------|
| Cases    | Percent (%) | Cases    | Percent (%) |
| Match    | 142   | 26.94  | 79       | 20.31 |
| No Match | 385   | 73.05   | 310      | 79.67 |
| Totals   | 527   | 100.00  | 389      | 100.00 |

Table 2: Recall comparison of IntEx and BioRAT from 229 abstracts when compared with DIP database.

| Results  | IntEx | BioRAT |
|----------|-------|--------|
| Cases    | Percent (%) | Cases    | Percent (%) |
| Correct  | 262   | 65.66  | 239       | 55.07 |
| Incorrect| 137   | 34.33  | 195       | 44.93 |
| Totals   | 399   | 100.00 | 434       | 100.00 |

Table 3: Precision comparison of IntEx and BioRAT from 229 abstracts.

Most of the errors encountered were due to the protein name tagging (45%). A detailed analysis of the causes for the loss in precision and recall is provided in Figure 5. DIP contains protein interactions from both abstracts and full text. Since our extraction system was tested only on the abstracts, the system missed out on some interactions that were only present in the full text of the abstract.

Second evaluation for the IntEx system was done to test the recall performance using a document that was also used to measure the recall performance of the GeneWays (Rzhetsky, Iossifov et al. 2004) system. Both systems performance was tested using the full text article (Friedman, Kra et al. 2001). GeneWays system achieves a recall of 65%. We ran our extraction system on the same

5 Dataset was obtained from Dr. David Corney by personal communication.

6 Dataset was obtained from Dr. Andrew Rzhetsky by personal communication.
text article and extracted 42 interactions corresponding to a comparable recall measure of 63.64%.

Figure 6: Analysis of types of errors encountered

7 CONCLUSION

In this paper, we present a fully automated extraction system to identify gene and protein interactions in biomedical text. Our extraction system handles complex sentences and extracts multiple interactions specified in a sentence. Experimental evaluations of the IntEx system with the state of the art semi-automated systems -- the BioRAT and GeneWays datasets indicates that our system performs better without the labor intensive rule engineering requirement. We have shown that a syntactic role-based approach compounded with linguistically sound interpretation rules applied on the full sentence’s parse can achieve better performance than existing systems which are based on manually engineered pattern and are both costly to develop and not as scalable as the automated mechanisms developed in this paper.

ACKNOWLEDGEMENTS

We would like to thank to both Dr. David Corney and Dr. Andrew Rzhetsky for sharing their evaluation datasets and results.
