Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Covid-19

The impact of COVID-19 lockdown on snacking habits, fast-food and alcohol consumption: A systematic review of the evidence

1. Introduction

The coronavirus disease 2019 (COVID-19), a severe acute respiratory syndrome, was first reported in Wuhan, China and on March, 11th 2020 the World Health Organization (WHO) declared a pandemic due to its rapid spread throughout the world [1]. In order to combat the pandemic, many governments enforced preventive measures of self-isolation and nationwide lockdowns of several degrees, so as by April 2020 more than a third of the global population was under lockdown [2]. People were forced to stay at home and practice online working and/or online learning and were allowed to leave their homes only for prespecified occasions, such as medical reasons, essential work, physical activity, purchasing food and in emergencies [2]. Such sudden changes in people's life influenced the lifestyle of millions of people worldwide. In this study we aimed to investigate the impact of the first COVID-19 lockdown period (March–May 2020) on snacking behavior, fast-food and alcohol consumption. A systematic search in PubMed®, Scopus® and Web of Science® databases was conducted and 32 studies were included. Changes in snacking, in fast-food and ordered food consumption and in alcohol intake were examined. Snacking was found to be increased for a significant portion of the population examined (18.9–45.1%), whereas fast food (15.0–41.3%) and ordered food (33.9%) showed a tendency towards decrease. As per alcohol consumption, an upward trend was observed in a significant part (10.4–51.0%) of the participants examined. The increased snacking and alcohol consumption observed for almost a third of the examined population could be alarming because long-term health problems could arise in cases of repeated lockdowns in the future. The observed downward trend in fast-food consumption and in frequency of ordered food could be an encouraging sign of turning to home-prepared foods, but further research is needed in this field.

negatively influences the quality of life (QoL) for both the consumer and his/her family members [12].

Undoubtedly, there is inadequate information about related changes in eating behaviors as well as alcohol consumption during this global health crisis, although several studies have been conducted at national level. This systematic review aims to investigate changes in specific dietary habits (snacking, fast-foods, ordered food) and alcohol consumption during the COVID-19 lockdown period compared to pre lockdown time.

2. Material and methods

An electronic search was conducted in PubMed®, Scopus® and Web of science® databases (up to 28 November 2020) using the index terms “junk food”, “fast food”, “take away”, “alcohol”, “ethanol”, “covid-19”, “Sars-Cov-2” and the final search string as well as more info about our search strategy can be found in Supplementary File 1.

Total records identified through database searching were 1485 and were added in a reference database. (EndNote X7 for Windows, Thomson Reuters). After removal of duplicates studies were screened independently by two reviewers DB and MC. Any disagreements regarding selection of the included studies and data extraction were solved by consensus. Inclusion criteria were adolescent (≥16 years old) and adult populations who were under lockdown restrictions due to the COVID-19. Studies in which included children (<16 years old) or symptomatic COVID-19 patients were excluded. Studies not in English language were also excluded.

This systematic review was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement [13] (Supplementary Table 1). The quality of the eligible studies was assessed using the modified Newcastle Ottawa Scale (NOS) for cross-sectional studies (Supplementary Table 2) [14]. Due to the fact that this is a rapid systematic review as COVID-19 is an emerging, rapidly evolving situation, a protocol for this systematic review was not written.

Data extraction of the included studies was independently conducted by two reviewers (DB and MC) using a previous standardized excel form. All disagreement were solved by consensus. Data extracted from each study were country origin, sex and number of participants, period and type of the survey. Moreover, we examined dietary changes and we extracted information regarding changes in snacking habit, fast-food and ordered food as well as alcohol consumption. Variables referred to dietary and alcohol changes were presented as percentages. Statistical significance of each study’s results was stated by p-values where this data was available.

3. Results

3.1. Search results

The process for the studies selection is presented as a flow diagram in Fig. 1. A total of 1489 studies were identified through databases and reference searching and after removal of 642 duplicates, 847 studies were screened. Hence, 32 studies [15–46] (all cross-sectional) were included in this systematic review. Characteristics of the 32 cross-sectional included studies can be found in Table 1.

3.2. Snacking habits

Several studies had examined changes in snacking behavior during the period of lockdown [22,24,28–30,32,34,37,38] and the results are shown in Table 2. In these studies 34.0–62.2% stated no changes in either frequency or portion of snacking consumption throughout the day [22,24,28,29,34,37,38]. Regarding the subjects who reported changes in snacking a tendency towards increase can be observed [22,24,29,34]. The highest increase (−45%) for snacking consumption compared to the pre-lockdown period was reported among the Lithuanian population [28].

3.3. Fast-food and ordered food consumption

Changes in fast-food consumption were reported in eight studies [19,20,24,25,28,34,35,46] and changes in ordered food were examined in three studies [15,18,23], whereas relevant results are summarized in Tables 3 and 4 respectively. In four studies, more than 50% of the participants’ fast-food consumption remained unchanged during lockdown [24,28,34,46]. In studies where consumption of fast food had changed during the lockdown restrictions, a downward trend was identified [19,20,24,25,28,34,35,46]. Less than 10% of the participants examined reported an increase in junk food consumption [24,28,34], in contrast to one study by Zajacova et al., in which an increased consumption was stated by 25.0% of the survey participants [46]. Regarding the frequency of food ordering and having food delivered at home, results varied as can be seen in Table 4, with two studies showing a decline [15,18], and one showing an increase [23] (see Table 5).

3.4. Alcohol consumption

Changes in alcohol consumption during the lockdown period were reported in 23 cross-sectional studies [16,17,21,23,24,26,29,31,33–36,38–46]. Results showed that in 17 out of those 23 studies, alcohol consumption remained unchanged during the lockdown for the majority of participants [17,21,23,24,26–28,33,35,36,38–41,43,44,46]. However, a tendency towards increased alcohol consumption has been observed for the rest of their examined participants (14.2–38.5%) in the majority of these studies (13 of 17) [17,23,24,26,27,35,38–41,43,44,46]. A decline in alcohol consumption for the majority of participants during the lockdown period was reported in four studies [16,31,34,45] and an increase of alcohol consumption was reported for the majority of the survey participants in two studies [29,42].

4. Discussion

According to our knowledge, this is the first systematic review which aim was to examine changes in snacking behavior (including both sweet and salty snacks), fast-food, food ordering habits, and alcohol consumption. In total 128292 subjects from 34 different countries around the world (Algeria, Australia, Bahrain, Belgium, Brazil, Canada, China, Egypt, France, Greece, India, Iraq, Italy, Jordan, Kuwait, Lebanon, Libya, Lithuania, Morocco, New Zealand, Oman, Palestine, Poland, Qatar, Saudi Arabia, Spain, Sudan, Syria, Tunisia, UAE, UK, USA, Yemen) were included in our systematic review, aiming to investigate potential changes in snacking and/or alcohol consumption during the first lockdown period of COVID-19.

The results of our study regarding snacking showed that although for the majority of the population examined (34.0–62.2%) snacking behavior remained unchanged during the lockdown [22,24,28,30,32,34,38], an increased consumption of both salty and sugar snacks was reported for a significant part of individuals (18.9–45.1%) [22,24,28–30,32,34,37,38]. It has to be noted that despite the considerable heterogeneity in the definition of “snacks” (including desserts, candy, chips, nuts, crackers, popcorns, etc.)
Differences in snacking behavior could be seen even within the same country. In particular, in a study lead by Pellegrini including only obese participants, 32.7% stated an increase in their daily snacking consumption during lockdown [32], whereas in the study lead by Scarmozzino, in which the population was not limited to obese people, only 18.9% reported increased consumption [38]. This could imply that for obese people, it was more difficult to control their snacking consumption during the lockdown period. Moreover, according Leech et al., snack consumption is not necessarily associated with amelioration in the overall quality of diet (especially in micronutrients intake) [50], but increase in adipose tissue had been observed [51]. Overeating (including mainly snacking) and weight gain during lockdown could lead to “Covibesity” that should not be disregarded, as it can be a potential risk factor for COVID-19 infection [52,53]. In addition, with respect to COVID-19 disease, due to the fact that a vaccine is not yet available for everyone, a balanced in macro- and micronutrients nutrition could be a method of prevention and management of the disease [54]. Therefore, these subjects could be at risk of becoming symptomatic COVID-19 patients compare to those following a balanced diet [55].

Our results with respect to alcohol during the lockdown period showed that for the majority of the population examined the consumption remained stable [17,21,23,24,26–28,33,35,36,38–41,43,44,46]. However, a significant portion of the population examined increased its alcohol consumption during the confinement time [17,23,24,26,27,29,35,38–44,46]. Heterogeneity in results regarding alcohol consumption can be observed even in the same country. Results from China varied, where in Sun et al. [42] more than a half of the included population has increased its alcohol consumption, whereas in Yan et al. around 25% reported an increase [45]. However, an Italian study reported an increase of homemade recipes for pizza and/or sweets [56]. Another explanation could be the fear of transmission of COVID-19 disease via packets of food and delivery services, but further research is needed in this field.
situation as well as the sudden change of daily life made people more prone to alcohol consumption compared to the end of lockdown. Similar assumptions were also made about results from France [35,36] and Australia [41,43], where a tendency towards decrease in alcohol consumption at the end of the lockdown in comparison to the beginning was observed. Results from USA were also differed between the studies [17,27,39]. In Avery et al. study, which was started in March, 14.3% of the participants reported increased alcohol consumption [17], in Sharma et al. study, which was

Not stated in the study. Calculated according to existing results.
conducted in April, 23.6% of the participants increased their alcohol consumption [39], and in Knell et al. study of which the survey ended in May, 38.5% of the participants reported an increase in their alcohol consumption [27]. The same pattern was also observed in polish population where 13.8–14.6% of subjects reported increased consumption in April [21,40] and 18.1% in May [24]. Therefore, the population in USA and Poland, in contrast to other studies included in this review were assessed according to the Ottawa Scale (Suppl. Table 2) and were characterized as representative, whereas in the study led by Robinson as not representative [33].

COVID-19 pandemic, led to several and sudden changes in people’s daily life and the lockdown period was full of stress and anxiety for unknown duration [41]. In order to cope with this, a significant portion of the population relapsed to previous abuse as reported by Zhao et al. [57]. Nevertheless, subjects who often consume alcohol are not only more prone to viral and bacterial infections (including COVID-19) due to their impaired immune system [58,59], to CVD in heavy drinking occasions [60], liver [61], and pancreas diseases [62], but they also affect the quality of life of people living around them (e.g. domestic violence, neuropsychiatric disorders) [63]. However, according to a recent systematic review the evidence is not enough regarding domestic violence and alcohol abuse during COVID-19 [64], but awareness of reliability of this data is always needed [65].

Among the strengths of our study is the number of studies included as well as the fact that a significant geographical part of the world was covered. Moreover, this is the first systematic review examining changes in eating patterns (snacking, fast-food, and ordered food) as well as in alcohol consumption. In addition, all studies included in this review were assessed according to the Newcastle–Ottawa Scale (Suppl. Table 2) and were characterized from satisfactory (5) to very good (9) quality. Limitations of our studies include the fact that only online/or via telephone questionnaires were used as a tool for all the surveys without any verification by other methods such as focused

interviews, food diaries etc., can influence the reliability of the collected data. Lastly, in this systematic review studies only in English language were included and therefore related studies published in other languages might have been missed.

5. Conclusions

During the period of lockdown due to the COVID-19 pandemic, changes in lifestyle behaviors were observed for a significant percentage of the global population. A tendency towards increased in snacking as well as in alcohol consumption should not be disregarded because long-term problems could be arising especially in cases of repeated lockdowns in future. The observed decrease in fast-food consumption and in frequency of ordered food demonstrate an encouraging turn to home-made foods. However, provision and campaigns regarding nutritional information could be useful in order to combat with this pandemic.

Funding

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Author distribution

DB and MC searched the databases; DB, DJ, and MC wrote the paper; R.J, and MJ made the necessary recommendations; and DB, DJ, R.J, and MJ revised the manuscript. All authors have read and approved the final version of manuscript.

Conflict of interest

The authors declare no conflict of interest.

Appendix A. Supplementary data
