THE CHROMATIC POLYNOMIALS OF SIGNED PETERSEN GRAPHS

MATTHIAS BECK, ERIKA MEZA, BRYAN NEVAREZ, ALANA SHINE, AND MICHAEL YOUNG

Abstract. Zaslavsky proved in 2012 that, up to switching isomorphism, there are six different signed Petersen graphs and that they could be told apart by their chromatic polynomials, by showing that the latter give distinct results when evaluated at 3. He conjectured that the six different signed Petersen graphs also have distinct zero-free chromatic polynomials, and that both types of chromatic polynomials have distinct evaluations at any positive integer. We developed and executed a computer program (running in SAGE) that efficiently determines the number of proper k-colorings for a given signed graph; our computations for the signed Petersen graphs confirm Zaslavsky’s conjecture. We also computed the chromatic polynomials of all signed complete graphs with up to five vertices.

Graph coloring problems are ubiquitous in many areas within and outside of mathematics. We are interested in certain enumerative questions about coloring signed graphs. A signed graph \( \Sigma = (\Gamma, \sigma) \) consists of a graph \( \Gamma = (V, E) \) and a signature \( \sigma \in \{\pm\}^E \). The underlying graph \( \Gamma \) may have multiple edges and, besides the usual links and loops, also half edges (with only one endpoint) and loose edges (no endpoints); the last are irrelevant for coloring questions, and so we assume in this paper that \( \Sigma \) has no loose edges. An unsigned graph can be realized by a signed graph all of whose edges are labelled with +. Signed graphs originated in the social sciences and have found applications also in biology, physics, computer science, and economics; see [4] for a comprehensive bibliography.

The chromatic polynomial \( c_\Sigma(2k+1) \) counts the proper \( k \)-colorings \( x \in \{0, \pm1, \ldots, \pm k\}^V \), namely, those colorings that satisfy for any edge \( vw \in E \)

\[ x_v \neq \sigma_{vw} x_w \]

and \( x_v \neq 0 \) for any \( v \in V \) incident with some half edge. Zaslavsky [2] proved that \( c_\Sigma(2k+1) \) is indeed a polynomial in \( k \). It comes with a companion, the zero-free chromatic polynomial \( c^*_\Sigma(2k) \), which counts all proper \( k \)-colorings \( x \in \{\pm1, \ldots, \pm k\}^V \).

The Petersen graph has served as a reference point to many proposed results in graph theory. Considering signed Petersen graphs, Zaslavsky [5] showed that, while there are \( 2^{15} \) ways to assign a signature to the fifteen edges, only six of these are different up to switching isomorphism (a notion that we will make precise below), depicted in Figure 1 (In our figures we represent a positive edge with a solid line and a negative edge with a dashed line.)

In [5] Zaslavsky proved that these six signed Petersen graphs have distinct chromatic polynomials; thus they can be distinguished by this signed-graph invariant. He did not compute the chromatic polynomials but showed that they evaluate to distinct numbers at 3 [5, Table 9.2]. He conjectured

Key words and phrases. Signed graph, Petersen graph, complete graph, chromatic polynomial, zero-free chromatic polynomial.

We are grateful to Thomas Zaslavsky and an anonymous referee for comments on an earlier version of this paper, and we thank Ricardo Cortez and the staff at MSRI for creating an ideal research environment at MSRI-UP. This research was partially supported by the NSF through the grants DMS-1162638 (Beck), DMS-0946431 (Young), and DMS-1156499 (MSRI-UP REU), and by the NSA through grant H98230-11-1-0213.
that the six different signed Petersen graphs also have distinct zero-free chromatic polynomials, and that both types of chromatic polynomials have distinct evaluations at any positive integer \[5\]. Our first result confirms this conjecture.

**Theorem 1.** The chromatic polynomials of the signed Petersen graphs (denoted \(P_1, \ldots, P_6\) in Figure 1) are

\[
\begin{align*}
c_{P_1}(2k + 1) &= 1024k^{10} - 2560k^9 + 3840k^8 - 4480k^7 + 3712k^6 \\
&\quad - 1792k^5 + 160k^4 + 480k^3 - 336k^2 + 72k, \\
c_{P_2}(2k + 1) &= 1024k^{10} - 2560k^9 + 3840k^8 - 4480k^7 + 3968k^6 \\
&\quad - 2560k^5 + 1184k^4 - 352k^3 + 48k^2, \\
c_{P_3}(2k + 1) &= 1024k^{10} - 2560k^9 + 3840k^8 - 4480k^7 + 4096k^6 \\
&\quad - 2944k^5 + 1696k^4 - 760k^3 + 236k^2 - 40k, \\
c_{P_4}(2k + 1) &= 1024k^{10} - 2560k^9 + 3840k^8 - 4480k^7 + 4224k^6 \\
&\quad - 3200k^5 + 1984k^4 - 952k^3 + 308k^2 - 52k, \\
c_{P_5}(2k + 1) &= 1024k^{10} - 2560k^9 + 3840k^8 - 4480k^7 + 4096k^6 \\
&\quad - 3072k^5 + 1920k^4 - 960k^3 + 320k^2 - 48k, \\
c_{P_6}(2k + 1) &= 1024k^{10} - 2560k^9 + 3840k^8 - 4480k^7 + 4480k^6 \\
&\quad - 3712k^5 + 2560k^4 - 1320k^3 + 460k^2 - 90k.
\]

**Figure 1.** The six switching-distinct signed Petersen graphs.
Their zero-free counterparts are

\[
c_{P_1}(2k) = 1024k^{10} - 7680k^9 + 26880k^8 - 58240k^7 + 86592k^6 - 91552k^5 + 68400k^4 - 34440k^3 + 10424k^2 - 1408k,
\]

\[
c_{P_2}(2k) = 1024k^{10} - 7680k^9 + 26880k^8 - 58240k^7 + 86848k^6 - 93088k^5 + 72304k^4 - 39880k^3 + 14792k^2 - 3288k,
\]

\[
c_{P_3}(2k) = 1024k^{10} - 7680k^9 + 26880k^8 - 58240k^7 + 87104k^6 - 94320k^5 + 75664k^4 - 44320k^3 + 18192k^2 - 4222k,
\]

\[
c_{P_4}(2k) = 1024k^{10} - 7680k^9 + 26880k^8 - 58240k^7 + 87360k^6 - 95776k^5 + 78480k^4 - 47760k^3 + 20640k^2 - 5660k.
\]

Consequently (as a quick computation with a computer algebra system shows), none of the difference polynomials \(c_{P_m}(2k + 1) - c_{P_n}(2k + 1)\) and \(c_{P_m}^*(2k) - c_{P_n}^*(2k)\), with \(m \neq n\), have a positive integer root.

To compute the above polynomials, we developed and executed a computer program (running in SAGE [1]) that efficiently determines the number of proper \(k\)-colorings for any signed graph. We include our code in the appendix and at math.sfsu.edu/beck/papers/signedpetersen.sage.

We also used our program to compute the chromatic polynomials of all signed complete graphs up to five vertices; up to switching isomorphism, there are two signed \(K_3\)’s, three signed \(K_4\)’s, and seven signed \(K_5\)’s. As with the signed Petersen graphs, the chromatic polynomials distinguish these signed complete graphs:
Figure 2. The switching classes of signed complete graphs.

Theorem 2. The chromatic polynomials of the signed complete graphs (denoted $K_3^{(1)}, K_3^{(2)}, \ldots, K_5^{(7)}$ in Figure 2) are

\begin{align*}
c_{K_3^{(1)}}(2k + 1) &= 8k^3 - 2k, \\
c_{K_3^{(2)}}(2k + 1) &= 8k^3, \\
c_{K_4^{(1)}}(2k + 1) &= 16k^4 - 16k^3 - 4k^2 + 4k, \\
c_{K_4^{(2)}}(2k + 1) &= 16k^4 - 16k^3 + 4k^2, \\
c_{K_4^{(3)}}(2k + 1) &= 16k^4 - 16k^3 + 12k^2 - 2k, \\
c_{K_5^{(1)}}(2k + 1) &= 32k^5 - 80k^4 + 40k^3 + 20k^2 - 12k, \\
c_{K_5^{(2)}}(2k + 1) &= 32k^5 - 80k^4 + 64k^3 - 16k^2, \\
c_{K_5^{(3)}}(2k + 1) &= 32k^5 - 80k^4 + 88k^3 - 48k^2 + 10k, \\
c_{K_5^{(4)}}(2k + 1) &= 32k^5 - 80k^4 + 72k^3 - 28k^2 + 4k, \\
c_{K_5^{(5)}}(2k + 1) &= 32k^5 - 80k^4 + 96k^3 - 56k^2 + 12k, \\
c_{K_5^{(6)}}(2k + 1) &= 32k^5 - 80k^4 + 80k^3 - 40k^2 + 8k, \\
c_{K_5^{(7)}}(2k + 1) &= 32k^5 - 80k^4 + 120k^3 - 80k^2 + 20k.
\end{align*}
The corresponding zero-free chromatic polynomials are
\[
\begin{align*}
c^*_{K^3}(2k) &= 8k^3 - 12k^2 + 4k, \\
c^*_{K^3}(2k) &= 8k^3 - 12k^2 + 6k, \\
c^*_{K^4}(2k) &= 16k^4 - 48k^3 + 44k^2 - 12k, \\
c^*_{K^4}(2k) &= 16k^4 - 48k^3 + 52k^2 - 24k, \\
c^*_{K^4}(2k) &= 16k^4 - 48k^3 + 60k^2 - 34k, \\
c^*_{K^5}(2k) &= 32k^5 - 160k^4 + 280k^3 - 200k^2 + 48k, \\
c^*_{K^5}(2k) &= 32k^5 - 160k^4 + 304k^3 - 272k^2 + 114k, \\
c^*_{K^5}(2k) &= 32k^5 - 160k^4 + 328k^3 - 340k^2 + 174k, \\
c^*_{K^5}(2k) &= 32k^5 - 160k^4 + 312k^3 - 296k^2 + 136k, \\
c^*_{K^5}(2k) &= 32k^5 - 160k^4 + 336k^3 - 360k^2 + 190k, \\
c^*_{K^5}(2k) &= 32k^5 - 160k^4 + 320k^3 - 320k^2 + 158k, \\
c^*_{K^5}(2k) &= 32k^5 - 160k^4 + 360k^3 - 420k^2 + 240k.
\end{align*}
\]

We now review a few constructs on a signed graph \( \Sigma = (V, E, \sigma) \) and describe our implementation. The \textit{restriction} of \( \Sigma \) to an edge set \( F \subseteq E \) is the signed graph \((V, F, \sigma|_F)\). For \( e \in E \), we denote by \( \Sigma - e \) (the \textit{deletion} of \( e \)) the restriction of \( \Sigma \) to \( E - \{e\} \). For \( v \in V \), denote by \( \Sigma - v \) the restriction of \( \Sigma \) to \( E - F \) where \( F \) is the set of all edges incident to \( v \). A component of the signed graph \( \Sigma = (\Gamma, \sigma) \) is \textit{balanced} if it contains no half edges and each cycle has positive sign product.

\textit{Switching} \( \Sigma \) by \( s \in \{\pm\}^V \) results in the new signed graph \((V, E, \sigma^s)\) where \( \sigma^s_{vw} = s_v \sigma_{vw} s_w \). Switching does not alter balance, and any balanced signed graph can be obtained from switching an all-positive graph \([3]\). We also note that there is a natural bijection of proper colorings of \( \Sigma \) and a switched version of it, and this bijection preserves the number of proper \( k \)-colorings. Thus the chromatic polynomials of \( \Sigma \) are invariant under switching.

The \textit{contraction} of \( \Sigma \) by \( F \subseteq E \), denoted by \( \Sigma/F \), is defined as follows \([3]\): switch \( \Sigma \) so that every balanced component of \( F \) is all positive, coalesce all nodes of each balanced component, and discard the remaining nodes and all edges in \( F \); note that this may produce half edges. If \( F = \{e\} \) for a link \( e \), \( \Sigma/e \) is obtained by switching \( \Sigma \) so that \( \sigma(e) = + \) and then contracting \( e \) as in the case of unsigned graphs, that is, disregard \( e \) and identify its two endpoints. If \( e \) is a negative loop at \( v \), then \( \Sigma/e \) has vertex set \( V - \{v\} \) and edge set resulting from \( E \) by deleting \( e \) and converting all edges incident with \( v \) to half edges. The chromatic polynomial satisfies the deletion–contraction formula \([2]\)

\[c_\Sigma(2k + 1) = c_{\Sigma-e}(2k + 1) - c_{\Sigma/e}(2k + 1).\]

The zero-free chromatic polynomial \( c^*_\Sigma(2k) \) satisfies the same identity provided that \( e \) is not a half edge or negative loop. We will use \([1]\) repeatedly in our computations.

We encode a signed graph \( \Sigma \) by its \textit{incidence matrix} as follows: first \textit{bidirect} \( \Sigma \), i.e., give each edge an independent orientation at each endpoint (which we think of as an arrow pointing towards or away from the endpoint), such that a positive edge has one arrow pointing towards one and away
from the other endpoint, and a negative edge has both arrows pointing either towards or away from the endpoints. The incidence matrix has rows indexed by vertices, columns indexed by edges, and entries equal to $\pm 1$ according to whether the edge points towards or away from the vertex (and 0 otherwise). Since half edges and negative loops have the same effect on the chromatic polynomial of $\Sigma$, we may assume that $\Sigma$ has no half edge.

Deletion–contraction can be easily managed by incidence matrices: deletion of an edge simply means deletion of the corresponding column; contraction of a positive edge $vw$ means replacing the rows corresponding to $v$ and $w$ by their sum and then deleting the column corresponding to the edge $vw$ (it is sufficient to only consider contraction of positive edges, since we can always switch one of its endpoints if necessary, which means negating the corresponding row). Note that this process works for both links and half edges. Note also that we will constantly look for multiple edges (with the same sign) and replace them with a single edge.

Thus we can keep track of incidence matrices as we recursively apply deletion–contraction, leading to empty signed graphs or signed graphs that only have half edges; both have easy chromatic polynomials.

### Appendix: Code

Below is the SAGE code (which can be loaded into any SAGE terminal) used to compute chromatic polynomials of signed graphs. The procedure `chrom` is the main method which takes an incidence matrix and outputs the chromatic polynomial as an expression.

```python
#All positive edges in columns have a 1 and -1 entry. Standardize makes any
#positive edge column have the 1 come before the -1 when reading the column
#top to bottom. All negative edges in columns have two 1 entries or two -1 entries.
#Standardize makes any negative edge column have two 1s. Negative loops have
#one 1 or -1 entry in its edge column. Standardize makes all negative loop
#columns have one 1. Standardizing our edges into one convention makes finding a
#positive edge to delete-contrace more efficient.
def standardize(G):
