Improving nitrogen use efficiency (NUE) is a very important goal of crop breeding throughout the world. Cassava is an important food and energy crop in tropical and subtropical regions, and it mainly use nitrate as an N source. To evaluate the effect of the nitrate transporter gene *MeNPF4.5* on the uptake and utilization of N in cassava, two *MeNPF4.5* overexpression lines (*MeNPF4.5* OE-22 and *MeNPF4.5* OE-34) and one *MeNPF4.5* RNA interference (RNAi) line (*MeNPF4.5* Ri-1) were used for a tissue culture experiment, combining with a field trial. The results indicated that *MeNPF4.5* is a plasma membrane transporter mainly expressed in roots. The gene is induced by NO$_3^-$.

Compared with the wild type, *MeNPF4.5* OE-22 exhibited improved growth, yield, and NUE under both low N and normal N levels, especially in the normal N treatment. However, the growth and N uptake of RNAi plants were significantly reduced, indicating poor N uptake and utilization capacity. In addition, photosynthesis and the activities of N metabolism-related enzymes (glutamine synthetase, glutamine oxoglutarate aminotransferase, and glutamate dehydrogenase) of leaves in overexpression lines were significantly higher than those in wild type. Interestingly, the RNAi line increased enzymatic activity but decreased photosynthesis. IAA content of roots in overexpressed lines were lower than that in wild type under low N level, but higher than that of wild type under normal N level. The RNAi line increased IAA content of roots under both N levels. The IAA content of leaves in the overexpression lines was significantly higher than that of the wild type, but showed negative effects on that of the RNAi lines. Thus, our results demonstrated that the *MeNPF4.5* nitrate transporter is involved in regulating the uptake and utilization of N in cassava, which leads to the increase of N metabolizing enzyme activity and photosynthesis, along with the change of endogenous hormones, thereby improving the NUE and yield of cassava. These findings shed light that *MeNPF4.5* is involved in N use efficiency use in cassava.

**Keywords:** cassava, nitrate transport, nitrogen efficiency, growth, *MeNRT1.1/MeNPF4.5*
INTRODUCTION

Cassava (Manihot esculenta Crantz) is one of the three major root and tuber crops in the world, and it is the sixth largest food crop globally. It is known as the “underground granary” and “king of starch” because of its importance as a source of food, feed, and industrial processing material, and it is also an important energy crop (Zhuang et al., 2011). Nitrogen (N) is the major limiting factor for cassava yield. Fertilizers are necessary for increasing storage root yields, and thus excessive amounts of N fertilizer may be applied to obtain high yields. However, the N use efficiency (NUE) has decreased from 68 to 47% over the past 50 years (Lassaletta et al., 2014), and more than half of the N applied is lost to the environment. Excessive application of N fertilizer results in leaching of N from farmlands through surface runoff and water pollution (Li et al., 2017; Kyriacou et al., 2018). Because of this, reducing the amount of N fertilizer and improving the NUE of crops have become increasingly important goals for breeders. This is also the case for cassava, where improving the efficiency of N uptake and use is of important theoretical and practical significance for improving the ecological environment, ensuring food safety, and addressing food shortages due to population growth.

Most plants use nitrate (NO$_3^-$) as the main source of N (Wang W. et al., 2018). NO$_3^-$ is a nutrient that regulates plant growth and development (Fenchel et al., 2012), and it also acts as a signaling substance regulating gene transcription, thus affecting seed germination, plant root growth, and leaf stomatal activity (Wang et al., 2012). The uptake and transport of NO$_3^-$ in the roots and its redistribution among cells are realized through NO$_3^-$ transporters (NRTs). By using isotopic tracers $^{13}$N and $^{15}$N, two NO$_3^-$ transport systems have been found in higher plants: the high-affinity transport system, which mainly functions under low external NO$_3^-$ concentrations (<0.50 mM), and the low-affinity transport system, which mainly functions under high external NO$_3^-$ concentrations (≥0.50 mM) (Miller et al., 2007; Wang Y. Y. et al., 2018; Gao et al., 2019). High- and low-affinity NRTs are encoded by the NRT2 and NRT1 gene families, respectively. The Nitrate Transporter 1 (NRT1) gene family got its name because it was originally found to have the function of transporting NO$_3^-$, the function of transporting dipeptides was found later and then was further classified as the PEPTIDE TRANSPORTER (PTR) family. However, several studies in the past few years confirmed that an even wider range of molecules are transported by some family members (Zhou et al., 1998; Jeong et al., 2004). Léran et al. (2014) renamed it as NPF (NRT1/PTRFAMILY) family according to its systematic evolutionary characteristics. Currently, 53 NRT1/PTR family members and seven NRT2 family members have been found in Arabidopsis thaliana (Okamoto et al., 2003). AtNRT1.1 also known as CHL1 and AtNPF6.3, was the first member identified as a low-affinity transporter, but it also functions as a high-affinity transporter at low external NO$_3^-$ concentrations depending upon its phosphorylation state (Liu et al., 1999; Ho et al., 2009; Guo et al., 2014). It plays a key role in sensing and triggering many adaptive changes in response to external NO$_3^-$, such as stimulating lateral root elongation in NO$_3^-$ rich patches (Remans et al., 2006). NRT1.1 can activate these responses through many independent mechanisms, which can be uncoupled by introducing point mutations in different regions of the protein (Bouguyon et al., 2015). In addition to NO$_3^-$ uptake, NRT1.1 regulates the expression of many NO$_3^-$ responsive genes (Undurraga et al., 2017). Furthermore, NRT1.1 is a master player in the NO$_3^-$ mediated regulation of root system architecture because it stimulates the growth of lateral roots and tap roots of Arabidopsis (Remans et al., 2006; Fan et al., 2017; Maghiaoui et al., 2021). Some NRT1 family proteins transport NO$_3^-$ and other diverse compounds, such as nitrite (Sugira et al., 2007), amino acids (Zhou et al., 1998), peptides (Komarova et al., 2008), and phytohormones including auxin (Krouk et al., 2010), gibberelin (Tal et al., 2016), and abscisic acid (Kanno et al., 2012), which indicates that they have versatile functions.

At present, NRT/NPF genes have mainly been identified in A. thaliana and rice, and their functions and regulatory mechanisms have been studied in detail (Liu et al., 2015; Sakuraba et al., 2021). For example, studies have shown that rice NRT1.1B is located in the cell membrane and plays an important role in the transport of NO$_3^-$ from the adventitious roots to the leaves (Hu et al., 2015; Zhao et al., 2017). Cassava is an allopolyploid species (2n = 36) with a highly heterozygous genome, therefore, the function and expression of NRT genes in cassava deserve our attention. MeNRT2.1 of cassava was found to be mainly expressed in the root system, and transient expression experiments in protoplasts revealed that the MeNRT2.1 protein is localized on the cell membrane (Zou et al., 2019). Ren et al. (2019) discovered that the MeNRT2.5 gene was expressed in the roots, stems, leaves, flowers, and other organs, with relatively high expression in the roots of mature cassava plants and the leaves of tissue-cultured seedlings; and the expression of this gene was found to be inhibited by high concentrations of NO$_3^-$.

Despite the progress in characterizing members of the NRT2 gene family, there has been no report on the NRT1 gene family in cassava. In this study, the MeNPF4.5 (MeNRT1.1) gene was identified and found to be mainly expressed in cassava roots. Overexpression of this gene in cassava improved the yield of storage roots by increasing the activities of enzymes related to N metabolism and enhancing photosynthesis. In contrast, RNA interference (RNAi) significantly decreased yield, which indicated that MeNPF4.5 plays a vital role in cassava growth by regulating the metabolism and distribution of N.

MATERIALS AND METHODS

Phylogenetic Analysis of NRT1.1

For phylogenetic analysis of NRT1.1, amino acid sequences of NRT1 from different species were obtained from GeneBank and sequence alignment was carried out using DNAMAN software (version 9.0). A phylogenetic tree based on entire amino acid sequences was constructed using the neighbor-joining method with 1000 bootstrap replicates in MEGA 7.0 (Li et al., 2018).
Plasmid Construction and Cassava Transformation

Cassava MeNPF4.5 (GeneBank accession No. KU361329.1) was cloned from the root cDNA of TMS60444 seedlings, which was cultured in normal condition without NO\textsubscript{3}\textsuperscript{−} induction. MeNPF4.5 was controlled by the CaMV 35S promoter. The expression cassettes were inserted into the binary vector pCAMBIA1301 containing the hygromycin phosphotransferase under the control of the CaMV 35S promoter to generate pCpCAMBIA1301 containing the hygromycin phosphotransferase. And a binary expression vector p35S:MeNPF4.5 was constructed according to previous report (Vanderschuren et al., 2009). The plasmids were mobilized into Agrobacterium under the control of the CaMV 35S promoter to generate pCpCAMBIA1301 containing the hygromycin phosphotransferase.

Subcellular Localization of MeNPF4.5 Protein

The open reading frame of MeNPF4.5 without a stop codon was amplified using MeNPF4.5 gene-specific primers (F: cagtGGTCTCacaacagtctttactgactta; R: cagtG GTCTCatacaactgtatcaattcga cct) The PCR amplification product was cloned into the pBWA(V)HS-ccdb-GLosgfp vector to generate the MeNPF4.5-enhanced green fluorescent protein (EGFP) C-terminal fusion construct, and 35S-EGFP was used as a negative control. The recombinant plasmids were transferred into Agrobacterium tumefaciens LBA4404, and cassava TMS60444 was used as donor plant to produce transgenic plants. Transgenic plants were produced by reported methods (Zhang et al., 2000).

Cassava Tissue Culture Experiment

The tested materials were the wild-type cassava (Manihot esculenta Crantz) cultivar TMS60444 (WT), overexpression lines MeNPF4.5 OE-22 and MeNPF4.5 OE-34, and RNAi line MeNPF4.5 Ri-1. The stems of WT and MeNPF4.5 transgenic cassava (with one sprout) were subcultured in 1/2 Murashige-Skoog (MS) (Murashige and Skoog, 1962) medium (Hope Bio-Technology, Qingdao, China) in a tissue culture room for 10 days. Germinated seedlings were then transferred in MS medium without N–NH\textsubscript{4}\textsuperscript{+}, and the medium was supplemented with KNO\textsubscript{3} as a sole N source at the concentrations as indicated in each individual experiment. Three NO\textsubscript{3} treatments as follows, N-free: 0 mM, low-N: 0.5 mM, and full-N: 20 mM. For N-free and low-N conditions, ion equilibrium of the medium was ensured by replacing KNO\textsubscript{3} by K\textsubscript{2}SO\textsubscript{4}. The pH of the medium was adjusted to 6.0 by using NaOH. The cassava seedlings were then incubated at 26°C and 50% relative humidity with a 14 h light/10 h dark cycle. Light intensity during the day period was 250 µmol m\textsuperscript{−2} s\textsuperscript{−1}. The medium contained 25 g L\textsuperscript{−1} sucrose and 1 g L\textsuperscript{−1} Gelrite. The roots were cut at the distance of 1.5 cm from root tip, stems were cut at the distance of 1.5 cm from tip, and the second expanded leaves samples were harvested 25 days after treatment with NO\textsubscript{3}−, frozen in liquid nitrogen, and stored at −80°C until further use.

Field Experiment

Field experiment was performed in 2016 at Jiatapo, Dingxi Village, Pumiao Town, Nanning City (22°81’N, 108°63’E).
The soil test was evenly flat and had uniform fertility. The chemical compositions of the cultivated soil layers before the experiment are listed in Supplementary Table 1. According to the NY/T1749-2009 Soil Fertility Diagnosis and Evaluation Method of Farmland in Southern China standards for total N (1.0 g kg\(^{-1}\)) and available N (105 mg kg\(^{-1}\)), the soil layers of the test plot were low in N.

A double factor split-plot design was used for field trial; the main and sub-plots were N treatment and cassava lines, respectively. There were two N treatments, low (0 kg ha\(^{-1}\), N0) and normal N (125 kg ha\(^{-1}\), N1), and the N fertilizer was urea (containing 46.7% N). A random block design was adopted with three replications. The same amounts of phosphorus (P) and potassium (K) fertilizers were used for all plots (P\(_2\)O\(_5\) 48 kg ha\(^{-1}\); K\(_2\)O 162 kg ha\(^{-1}\)). Super phosphate was used as a P fertilizer, and potassium chloride was used as a K fertilizer. The P fertilizer was applied once at sowing, while the N and K fertilizers were applied thrice: 50% as a base fertilizer, 25% at 40 days after sowing, and 25% at 90 days after sowing.

For the basal fertilizer application, a 10 cm deep groove was dug at a distance of 15 cm away from the cassava stem; all the basal fertilizers were applied evenly in the groove and covered with soil. For the top dressing, the fertilizer was dissolved in water and then applied quantitatively to each plant. The size of the subplot was 10 m\(^2\) (1 m \(\times\) 10 m), and the distance between cassava plants was 1 m \(\times\) 1 m. To prevent leaching of the fertilizer from the N1 plot to the N0 plot, the two N treatment plots were separated by 1 m. The cassava plants were planted on May 10, 2016, and conventional field management methods were used during the entire growth period. Plants were harvested for agronomic trait evaluation and subsequent experiments on January 10, 2017.

**Nitrogen Use Efficiency and Metabolism Enzyme Assays**

During the harvesting of cassava, the fresh weights of leaves, stems, and storage roots of individual plants were measured. A fixed amount of each component was collected and dried at 105°C for 30 min and then further dried at 65°C to a constant weight. Tissue N concentration was determined by the micro-Kjeldahl method (Mishra et al., 2016) after digestion by concentrated H\(_2\)SO\(_4\)-H\(_2\)O\(_2\).

The methods for calculating each indicator were as follows:

- Dry matter mass of the whole plant \(\left(\text{t ha}^{-1}\right)\) = dry storage root weight + dry stem weight + dry leaf weight (Kang et al., 2020).
- N accumulation (g plant\(^{-1}\)) = N content of the organ \(\times\) dry matter mass of the organ (Kang et al., 2020).
- Transport index (%) = Shoot N content/(Root N content + Shoot N content) \(\times\) 100 (Lérán et al., 2013).
- N utilization efficiency (kg kg\(^{-1}\)) = Plant dry weight/N accumulation (Kang et al., 2020).

The photosynthetic activity of the fifth expanded leaves from plants grown for 3 months was measured with a 6400XT (LI-COR, Lincoln, Nebraska, United States) photosynthesis system on a sunny day from 9:00 to 11:00 in the morning. The net photosynthetic rate (Pn), intercellular CO\(_2\) concentration (Ci), stomatal conductance (Gs), and transpiration rate (Tr) were determined. The photosynthetic photon flux density was 1,200 \(\mu\text{mol m}^{-2}\text{s}^{-1}\).

The following chlorophyll fluorescence parameters were recorded from leaves at the same position as those used for photosynthetic parameter measurements using an imaging chlorophyll fluorimeter (Walz Imaging PAM, Walz GmbH, Effeltrich, Germany): Fv/Fm (PS II maximum quantum yield of photosynthesis), Y(II) (PS II actual quantum yield of photosynthesis), qP (photochemical quenching coefficient), and qN (non-photochemical quenching coefficient). The measurements were conducted at room temperature (25°C) using the standard saturated light mode. The actinic light intensity was 10 \(\mu\text{mol m}^{-2}\text{s}^{-1}\). Prior to detection, leaves were adapted to darkness for 30 min.

**Endogenous Hormone Analysis**

Cassava seedlings were cultivated in tissue culture under different N conditions (0.5 and 20 mM NO\(_3^−\)) for 25 days, and then the endogenous hormone content in the roots (excised from 1.5 cm of primary root tips) and leaves (the second expanded leaves) of WT and transgenic plants were analyzed. The extraction, purification and determination of endogenous hormones levels were assayed by an indirect enzyme-linked immunosorbent assay (ELISA) technique, which performed with a kit from the Beijing Benongda Tianyi Biotechnology Co. (Beijing, China) according to the manufacturer’s instructions.

**Statistical Analysis**

Data from at least three biological replicates are presented as the mean ± SE. Analysis of variance (ANOVA) followed by
independent sample Student’s t-test was performed using SPSS software version 22.0 (IBM Corp., Armonk, NY, United States). $P < 0.05$ was considered statistically significant.

**RESULTS**

**Phylogenetic Analysis of NRT1.1 and MeNPF4.5 Is a Plasma Membrane Localized Protein**

Phylogenetic analysis showed that MeNPF4.5 is closely related to CsNRT1.2 of *Camellia sinensis* and HaNRT1.2 of *Helianthus annuus*. These results showed that MeNPF4.5 is a member of the NRT1/NPF subfamily (*Figure 1*).

A 35S-MeNPF4.5-EGFP fusion protein construct was used to determine the subcellular localization of MeNPF4.5, and 35S-EGFP served as control. The constructs were transiently transformed into leaf cells of *Nicotiana* using agroinfiltration. MeNPF4.5-EGFP was expressed in the plasma membrane, whereas EGFP was detected not only in the plasma membrane, but also in the cytoplasm and nucleus (*Figure 2D*). These results indicated that MeNPF4.5 is a transmembrane transport protein.

**Expression of MeNPF4.5 Is Tissue Specific**

To analyze the expression of *MeNPF4.5* in response to different N levels, young cassava seedlings were grown in N-free (0 mM $\text{NO}_3^-$), low-N (0.5 mM $\text{NO}_3^-$), and full-N (20 mM $\text{NO}_3^-$) media. We found that the expression level of *MeNPF4.5* in roots significantly decreased under N-free conditions. Compared with the N-free control where *MeNPF4.5* was expressed at the lowest levels, *MeNPF4.5* expression in roots was increased by 15.1-fold under low-N and 27.0-fold under full-N, which indicated that *MeNPF4.5* expression was induced by $\text{NO}_3^-$ (*Figure 2A*).

*MeNPF4.5* expression in roots was also analyzed with a time-course experiment. After $\text{NO}_3^-$ induction, the expression

---

**FIGURE 1** | Phylogenetic analysis of the MeNPF4.5 protein and other $\text{NO}_3^-$ transporters (NRTs). The amino acid sequences were aligned using ClustalW software and the phylogeny was constructed using the neighbor-joining method with 1000 bootstrap replicates in MEGA7.
of MeNPF4.5 increased rapidly and reached a peak at 2 h. Expression then decreased gradually and stabilized at 6 h, but then decreased again, reaching the lowest level at 12 h before increasing again at 24 h (Figure 2B). Analysis of expression in different tissues showed that MeNPF4.5 was expressed in stems and leaves in addition to roots; and the expression level was highest in roots under both 0.5 and 20 mM NO₃⁻, with expression levels 54.9- and 11.4-times higher than those in leaves, respectively (Figure 2C).

**Identification of MeNPF4.5 Transgenic Cassava Plants**

To investigate the function of MeNPF4.5, the 3 transgenic lines (overexpression lines MeNPF4.5 OE-22 and MeNPF4.5 OE-34, and RNAi line MeNPF4.5 Ri-1) were constructed. Southern blot analysis verified that the exogenous MeNPF4.5 gene had been integrated into the genomes of MeNPF4.5 OE-22 and MeNPF4.5 OE-34 (Supplementary Figure 1), which confirmed that the overexpression lines MeNPF4.5 OE-22 with a single copy of the transgenic construct and MeNPF4.5 OE-34 with two copies. Quantitative RT-PCR was used to assess the levels of MeNPF4.5 RNA in these lines. As shown in Figure 3A, the expression levels of MeNPF4.5 in MeNPF4.5 OE-22 and MeNPF4.5 OE-34 were significantly higher than those in the WT under both N conditions, and the expression level in the Ri-1 line was decreased by 39.7 and 70.4% under low and normal N conditions, respectively. Therefore, these three lines were used for further analysis.

**MeNPF4.5 Overexpression Enhances the Yield of Storage Roots**

Lush foliage is the basis for healthy and high-yielding crops. Field evaluation of MeNPF4.5 transgenic cassava showed that the two transgenic overexpression lines MeNPF4.5 OE-22 and MeNPF4.5 OE-34 and the RNAi line MeNPF4.5 Ri-1 exhibited significant differences from WT in both the aerial and underground parts (Figure 3). Three of the four agronomic traits examined, namely leaf dry weight, storage root yield, and biomass accumulation, were significantly higher in MeNPF4.5 OE-22 than in WT under both low and normal N conditions, whereas these trait values were lower in MeNPF4.5 Ri-1. There was no significant difference in plant height between MeNPF4.5 OE-22 and WT, but both lines were significantly taller than MeNPF4.5 OE-34 and MeNPF4.5 Ri-1 under both low and normal N conditions. These results demonstrated that NRT1.1 overexpression can improve plant growth under low or normal N conditions. However, no
FIGURE 3 | Molecular identification and analysis of agronomic traits of WT and transgenic plants. (A) Real-time RT-PCR analysis of MeNPF4.5 gene expression in the roots of WT and transgenic plants under 0.5 and 20 mM NO$_3^-$; MeNPF4.5 OE, MeNPF4.5 overexpression; MeNPF4.5 Ri, MeNPF4.5 RNA interference. The Actin gene was used as an internal control. (B–F) Agronomic traits of WT and transgenic plants grown in the field for 8 months under different N0 (0 kg ha$^{-1}$) and N1 (125 kg ha$^{-1}$) conditions. (B) Storage roots of cassava plants grown in the field. N0 treatment (upper panel), N1 treatment (lower panel); from left to right, WT, MeNPF4.5 OE-22, MeNPF4.5 OE-34, and MeNPF4.5 Ri-1 images are shown. Bars = 10 cm. (C) Plant height ($n=10$). (D) Leaf dry weight ($n=5$). (E) Storage root yield ($n=5$). (F) Biomass accumulation ($n=5$). Values are means ± SE. Lowercase letters above the bars (a–d) represent significant differences between treatments as determined by Student’s t-test ($P<0.05$); N0, low-N treatment, 0 kg ha$^{-1}$; N1, normal N treatment, 125 kg ha$^{-1}$.

Improvement in agronomic traits was observed for the MeNPF4.5 OE-34 line; all four traits examined were lower than those in WT and MeNPF4.5 OE-22, but higher than those in MeNPF4.5 Ri-1.

MeNPF4.5 Improves N Uptake, N Translocation, N Accumulation, and Nitrogen Use Efficiency

To determine the MeNPF4.5 function in NO$_3^-$ uptake by roots, we measured the NO$_3^-$ uptake of cassava roots. The results showed that the NO$_3^-$ uptake of WT and transgenic cassava roots increased gradually with increasing of NO$_3^-$ concentration. The NO$_3^-$ uptake was significantly higher in overexpression lines (MeNPF4.5 OE-22 and MeNPF4.5 OE-34) than those in the WT at relatively higher (1–20 mM) NO$_3^-$ concentration. However, no significant difference was found at relatively lower (0.25 mM) NO$_3^-$ concentrations. By contrast, the NO$_3^-$ uptake was significantly lower in MeNPF4.5 Ri-1 line than that in the WT at all tested NO$_3^-$ concentrations (Figure 4A). Therefore, it seems that MeNPF4.5 is involved in the function of NO$_3^-$ uptake.

Transport index was used as an indicator of NO$_3^-$ translocation from roots to shoots (Figure 4B). Translocation of NO$_3^-$ from roots to shoots between WT and transgenic lines, showing that the MeNPF4.5 Ri-1 plants have lower N enrichment in the shoots compared to those of WT and OE transgenic plants under both N conditions. However, N

MeNPF4.5 Increases Cassava Yield

FIGURE 4

Nitrogen uptake, translocation and accumulation in WT and MeNPF4.5 transgenic cassava plants. (A) Root NO$_3^-$ uptake in WT and MeNPF4.5 transgenic cassava plants. WT and MeNPF4.5 transgenic cassava plants grown in 20 mM KNO$_3$ for 25 days and then deprived of N for 3 days. N-starved plant roots were then exposed to various NO$_3^-$ concentrations for 6 h, uptake of NO$_3^-$ were measured by disappearance of NO$_3^-$ from the nutrient solution. (B) Nitrate translocation in WT and MeNPF4.5 transgenic cassava plants. (C–E) N accumulation in wild-type (WT) and MeNPF4.5 transgenic cassava plants harvested from the field. (C) Shoot N accumulation. (D) Root N accumulation. (E) Total N accumulation. Values are the means of three biological replicates ± SE. Lowercase letters above the bars (a–d) represent significant differences between treatments as determined by Student’s t-test (P < 0.05). N0, low-N treatment, 0 kg ha$^{-1}$; N1, normal N treatment, 125 kg ha$^{-1}$.

enrichment had no remarkable between OE transgenic plants (MeNPF4.5 OE-22 and MeNPF4.5 OE-34) and WT under the N0 and N1 conditions, indicating that the translocation of NO$_3^-$ to shoots is slower when MeNPF4.5 gene expression is suppressed, thus it can be seen that the MeNPF4.5 activity affects the NO$_3^-$ translocation from roots to shoots.

As NRT1.1 is one of the NRT genes involved in NO$_3^-$ uptake in roots, we analyzed the N accumulation of transgenic lines and WT plants. N accumulation is equal to the N content in each part of the plant multiplied by the biomass. As shown in Figures 4C–E, the amounts of shoot and whole-plant N accumulation in MeNPF4.5 OE-22 under low-N and normal N treatments were significantly higher than those in the WT, by 33.7% (N0) and 36.5% (N1) for shoots and by 29.5% (N0), 19.5% (N1) for the whole plant, but N accumulation was significantly lower in the MeNPF4.5 Ri-1 line than in the WT. The amounts of N accumulation in storage roots of MeNPF4.5 OE-22 were similar to those in WT under low-N conditions, but higher than those in WT under normal N conditions, which verified that NRT1.1 was induced by high NO$_3^-$ (≥0.50 mM). All these results show that NRT1.1 enhances NO$_3^-$ uptake and accumulation in cassava.

The NUE of crops is related to the N uptake efficiency and N utilization efficiency, but their contributions to N efficiency remain controversial (Bogard et al., 2013). Our results indicated that there were significant differences in N utilization efficiency (NUtE), N recovery efficiency (NRE), and the partial factor productivity of N (PFPN) of the different transgenic cassava lines. As shown in Table 1, there were no significant differences in NUtE (under N0) and NRE between MeNPF4.5 OE-22 and WT, but NUtE (under N1) and PFPN of MeNPF4.5 OE-22 were significantly higher than those of the WT (by 7.6 and 16.8%, respectively). The NUtE under both N levels, NRE, and PFPN of MeNPF4.5 Ri-1 were significantly lower than those of the WT (reduced by 36.4, 130.1, and 94.7%, respectively). MeNPF4.5 OE-34 had a lower NUtE (under N1), NRE, and PFPN than WT, but NUtE under N0 conditions was significantly higher than that in the WT. These results indicated that the MeNPF4.5 gene expression level could severely affect the activity of NPF4.5 transporter in uptake and utilization of N under different N levels.

MeNPF4.5 Increases the Activities of Enzymes Related to N Metabolism in Cassava Leaves

The N absorbed by crop roots must be assimilated into organic matter through N metabolism enzymes before it can be used by the plant. The activity of key N metabolism enzymes can directly reflect the strength of N metabolism in crops (Andrews et al., 2004). The activities of enzymes involved in N metabolism, namely NR, GS, GOGAT, and GDH, were higher in WT and all the transgenic plants under the N1 treatment than under the N0

N0, low-N treatment, 0 kg ha⁻¹; N1, normal N treatment, 125 kg ha⁻¹. Values are the means of three biological replicates ± SE. Values labeled with different letters represent significant differences between respective treatments by Student’s t-test (P < 0.05).

### FIGURE 5 | Activity of N metabolism enzymes. Activities of NR (A), GS (B), GOGAT (C), and GDH (D) in the leaves of WT and MeNPF4.5 transgenic cassava harvested from the field. Values are the means of three biological replicates ± SE. Lowercase letters above the bars (a–d) represent significant differences between treatments as determined by Student’s t-test (P < 0.05). N0, low-N treatment, 0 kg ha⁻¹; N1, normal N treatment, 125 kg ha⁻¹.

Treatment, which showed that high N promoted the activities of these enzymes (Figure 5). The activities of all enzymes except for NR were higher in MeNPF4.5 OE-34 and MeNPF4.5 Ri-1 than in MeNPF4.5 OE-22 and the WT under both the N0 and N1 conditions; at the same time, the activities of these enzyme were significantly higher in MeNPF4.5 OE-22 than in WT under the N1 conditions.

MeNPF4.5 Increases Photosynthesis

Photosynthesis is the physiological basis of crop growth and yield formation, and 90–95% of crop dry matter accumulation originates from photosynthetic products. As shown in Figures 6A–D, there was no significant difference in photosynthetic parameters, namely Gs, Ci, and Tr, between MeNPF4.5 OE-22, MeNPF4.5 OE-34, and WT under both N levels. The Pn of MeNPF4.5 OE-22 was 8.4% higher compared with that of WT under the N1 conditions. The Pn and Gs of MeNPF4.5 Ri-1 were significantly lower than those of WT under both N levels.

Chlorophyll fluorescence is a direct indicator of plant physiology and reflects the photochemical process and its efficiency. As photosynthesis was altered by the MeNPF4.5
MeNPF4.5 Regulates Endogenous Hormone Levels in Cassava

Significant changes were also detected in endogenous hormones, namely indoleacetic acid (IAA), zeatin-riboside (ZR), gibberellic acid (GA$_3$), abscisic acid (ABA), and brassinosteroid (BR), in the roots and leaves of transgenic cassava (Figures 7, 8). In roots, compared with WT, the levels of IAA were 11.8 and 25.8% lower in MeNPF4.5 OE-22 and OE-34, respectively, and 39.9% higher in MeNPF4.5 Ri-1 under low-N conditions (Figure 7). In contrast, under the full-N conditions the levels of IAA in transgenic plants (MeNPF4.5 OE-22, MeNPF4.5 OE-34, and MeNPF4.5 Ri-1) were 46.7, 65.2, and 38.2% higher than those in WT, respectively. For ZR and GA$_3$, very similar patterns were observed in transgenic plants under both N levels. All the transgenic lines had a significantly higher ZR and GA$_3$ contents than WT under both N conditions. Analysis of ABA revealed decreases of 20.5% in MeNPF4.5 OE-22 and 31.0% in MeNPF4.5 OE-34 compared with WT. ABA levels in MeNPF4.5 Ri-1 plants did not significantly differ from those in WT under low-N conditions. Under full-N conditions, the ABA content was higher compared with that in WT in all transgenic plants. Compared with WT plants, there was a 21.5% decrease of BR in MeNPF4.5 OE-22 and no significant difference between WT and the MeNPF4.5 OE-34 and MeNPF4.5 Ri-1 lines under low-N conditions. However, BR levels were higher in the three transgenic lines under full-N conditions. These results suggest that the MeNPF4.5 gene alters plant endogenous hormone levels in transgenic plants.

Analysis results on content of endogenous hormone in leaves showed that IAA in MeNPF4.5 OE-22 and MeNPF4.5 OE-34
were higher than those in WT under both N conditions, and IAA levels in MeNPF4.5 Ri-1 plants did not significantly differ from those in WT under full-N conditions but significantly lower than those in WT under low-N conditions (Figure 8). Compared with WT plants, there were significantly lower ZR contents in MeNPF4.5 OE-22 and MeNPF4.5 Ri-1 lines under low-N conditions. ZR levels in MeNPF4.5 OE-34 plants did not significantly differ from that in WT under low-N conditions. Under full-N conditions, the ZR content was lower compared with that in WT in the overexpression lines. Meanwhile, the overexpression lines MeNPF4.5 OE-22 and MeNPF4.5 OE-34 had a significantly lower GA3 contents than WT under full-N conditions. And the MeNPF4.5 Ri-1 lines had a significantly higher GA3 contents than those in WT under both N conditions.
DISCUSSION

NRT1.1/NPF6.3 (CHL1) was the first NRT gene discovered in plants, and it also was found to function not only in NO$_3^-$ uptake (Tsay, 1993) but also in NO$_3^-$ translocation from roots to shoots (Léran et al., 2014). At present, research on NRT1.1 has mainly focused on the model plant Arabidopsis and the food crops rice (Hu et al., 2015; Fan et al., 2017; Wang Y. Y. et al., 2018) and wheat (Guo et al., 2014). Little information regarding this family is available in cassava, an important crop in much of the world. In this study, we investigated the spatiotemporal expression pattern and the function of the MeNPF4.5 gene in cassava. Our data clearly showed that MeNPF4.5 was barely detectable under N deficiency conditions, but its expression was maintained at a high level under N sufficient conditions. This suggests that MeNPF4.5 expression could be induced by NO$_3^-$ just as AtNRT1.1 is in Arabidopsis (Lejay et al., 1999; Liu et al., 1999). Once N-starved cassava plants were exposed to NO$_3^-$, MeNPF4.5 expression first increased and then decreased (Figure 2A). It can be seen that MeNPF4.5 responds to NO$_3^-$ in the short term like many other plants NRT1.1 (Cárdenas Navarro et al., 1998; Okamoto et al., 2003; Wang et al., 2007). In addition to being expressed in roots, AtNRT1.1 is also expressed in shoots, young leaves, and developing flower buds of Arabidopsis, but it is more strongly expressed in roots (Miller et al., 2007; Sakuraba et al., 2021). Consistent with the expression pattern of NRT1.1 in Arabidopsis, MeNPF4.5 is expressed in roots, stems, and leaves of cassava plants, and it is predominantly expressed in roots. We also conducted subcellular localization studies on the MeNPF4.5 protein and found that it was located on the plasma membrane, which was consistent with the findings of previous studies on NRT1.1 (Hu et al., 2015; Zhao et al., 2017).

Nitrate affects all aspects of plant physiology including metabolism, resource allocation, growth, and development, and its accumulation and translocation are critical to dry matter production. NRTs are not only involved in the uptake and transport of NO$_3^-$ in roots, but also in the redistribution of NO$_3^-$ among cells. The influence of the expression of NRTs on the N uptake and NUE of crops are important topics in breeding research. For example, Hu et al. (2015) demonstrated that overexpression of indica-type OsNRT1.1B can potentially improve the NUE of the japonica variety Zhonghua. Furthermore, a recent study showed that 35S promoter- driven expression of OsNRT1.1A improves the grain yield of transgenic rice plants (Wang W. et al., 2018). Overexpression of the OsNRT1.2 in the rice cultivar ‘Wuyunjing 7’ resulted in a biomass increase under a high concentration of NO$_3^-$ (Ma et al., 2011). These results suggest an intimate relationship between the function of NRT1 and plant growth. To evaluate the effect of the MeNPF4.5 gene on cassava growth, we analyzed the yield and biomass of transgenic lines under two different N levels in a field test. Our results revealed differences between the overexpression lines and RNAi line; the yield and biomass of the overexpression lines were higher than those of the RNAi line. Compared with the WT, the growth of cassava was promoted in the overexpression line MeNPF4.5 OE-22 under both low and normal N conditions, while growth of the RNAi line MeNPF4.5Ri-1 was inhibited (Figure 3). This finding is consistent with the results of previous studies and shows that enhanced MeNPF4.5 expression could improve growth in cassava under both low and normal N conditions. However, another MeNPF4.5 overexpression line, MeNPF4.5 OE-34, exhibited inhibited growth compared with WT and MeNPF4.5 OE-22, although its growth was superior to that of MeNPF4.5Ri-1. This might be related to the high expression of MeNPF4.5 in this line, which may affect the balance between N uptake and utilization; or maybe MeNPF4.5 OE-34 has two copy of the transgenic construct, which might lead to the silence of target gene and thus affect plant growth (Vaucheret et al., 1998; Tenea et al., 2008; Ahalwat et al., 2014).

Nitrogen use efficiency can be simply defined as the yield of grain per unit of N available in the soil. NUE depends on N uptake efficiency and internal utilization efficiency, and N uptake-and-utilization efficiency reflects the capacity of crops to absorb N and transport it to the organs (Moll et al., 1982; Chen and Ma, 2015). Therefore, here we examined the association between N uptake, translocation, NUtE, and growth. OsNRT1.1B was reported to increase the NUtE of rice by 30% (Duan and Zhang, 2015; Hu et al., 2015), and Chen and Ma (2015) reported that OsNRT1.1B improves NUE in rice by enhancing root NO$_3^-$ uptake. Here we found that MeNPF4.5 enhanced N uptake, translocation, and accumulation in cassava; NUtE, NRE, and PFPN were improved in MeNPF4.5 overexpressing plants but were significantly lower in the MeNPF4.5 Ri-1 line compared with WT (Table 1). It is inferred that the higher yields of the overexpression lines MeNPF4.5 OE-22 and MeNPF4.5 OE-34 may be due to their high N uptake and transport capabilities, while the yield of MeNPF4.5 Ri-1 decreased because of its reduced N uptake and allocation.

N is absorbed by cassava in the form of NO$_3^-$, and then it needs to be assimilated mainly in shoot part into organic N through the catalytic action of several enzymes. Studies have found that when NO$_3^-$ addition to N-starved seedlings, all genes known to be directly required for NO$_3^-$ assimilation were strongly induced, including N metabolism enzyme gene (Govri et al., 1992; Wang et al., 2003; Scheible et al., 2004). Hu et al. (2009) also confirmed that NO$_3^-$ assimilation genes are regulated by NO$_3^-$, and these genes are expressed at low levels in the absence of NO$_3^-$ and are rapidly induced in its presence (priming effect). Much evidence suggests that NR and GS are the key enzymes for N assimilation (Thomsen et al., 2014). For most plants, there is a positive correlation between the amount of NO$_3^-$ absorbed by the roots from the soil and NR activity (Andrews et al., 2004). Meanwhile, GS enzyme...
activity and stability are positively correlated with substrate abundance (Andrews et al., 2004). Other enzymes responsible for N assimilation in addition to NR and GS, such as GOGAT, GDH, and asparagine synthetase, have also been reported to play important roles in N metabolism and improvement of NUE in plants (Ameziane et al., 2000; Wong et al., 2004; Yamaya and Kusano, 2014). In this study, we found that the activity of nitrogen metabolism enzymes in the same line under N1 level was higher than that under N0 level, indicating that N metabolism enzyme were induced by NO$_3^−$. The GS, GOGAT, and GDH activities in MeNPF4.5 OE-34 and MeNPF4.5 Ri-1 were higher than those in MeNPF4.5 OE-22 and the WT under both the N0 and N1 conditions, but there was no significant difference in NR activity. Although the activities of these enzymes were higher in MeNPF4.5 OE-34 and MeNPF4.5 Ri-1 than in the WT, the growth of these plants was inhibited and N accumulation was lower. Studies have shown that compared with the WT, transgenic rice that overexpress GS1 (Tabuchi et al., 2007) show no difference in growth phenotype and have lower yields. Transgenic tobacco plants that overexpress GS2 show limited growth and leaf yellowing (Thomsen et al., 2014). Some studies suggest that these phenomena may be the result of feedback inhibition of nitrogen metabolites (Vincentz and Caboche, 1991). The results of this study may also related to this phenomenon.

Previous studies found that there is a significant positive correlation between photosynthesis and crop yield and NUE (Zhang et al., 2017). However, some studies have pointed out that the substantial increase in crop yield achieved in the past few decades has not been accompanied by a significant increase in leaf Pn. The yield gain is mainly attributed to an increase in leaf area index and biological yield (Sharma-Natu and Ghidhiray, 2005). In this study, the leaf dry weight and Pn in MeNPF4.5 OE-22 were significantly higher compared with those in WT, while these two traits were significantly lower in the RNAi line. The Fv/Fm values in the RNAi line were also lower. Therefore, it is supposed that the difference in leaf area index and photosynthetic parameters may underlie the difference in NUE and yield between MeNPF4.5 OE-22 plants and MeNPF4.5 Ri-1 and WT plants.

Hormones play an important role in regulating various metabolic, growth, and development processes, and maintaining a dynamic balance under normal physiological conditions. Lots of plant hormones are transported by some NRT proteins and conversely regulate NRT gene expression (Zhao et al., 2021). NRT1.1 in roots can transport NO$_3^−$ and auxin, but preferentially transports NO$_3^−$ (Krouk et al., 2010; Bouguyon et al., 2015). Hormone metabolism appears transcriptional reprogramming and sensing as one of the early response to NO$_3^−$ addition (Scheible et al., 2004), while higher supply of NO$_3^−$ decreased IAA concentrations in phloem exudates, which affected root growth (Bhalerao et al., 2002; Tian et al., 2008; Liu et al., 2010). Krouk et al. (2010) propose that NRT1.1 represses lateral root growth at low NO$_3^−$ availability by promoting basipetal auxin transport out of these roots. In this study, we had the similar results, the IAA content in roots of the two overexpression lines was significantly lower compared with that of WT under low-N conditions, was higher in roots of RNAi line, which might be resulted from MeNPF4.5 promoting basipetal auxin transport and lowering auxin accumulation in the roots in OE plants, while the transport ability was inhibited in RNAi lines. Under full-N conditions, it was speculated that MeNPF4.5 performed the NO$_3^−$ transport function, which could lead to higher IAA content in roots of the transgenic lines than in that of WT. In addition, our results showed that the content of IAA in leaves of overexpressed lines remained at a high level under both N levels, which may be related with a higher translocation of N toward the aerial parts associated with more production of IAA. Previous studies found that the change of IAA levels in the root was closely related to NO$_3^−$ mediated root growth, however, the latter process could not be explained exclusively by the former, due to NO$_3^−$ has a comprehensive effect on other phytohormones, such as cytokinin (Beck, 1996; Takei et al., 2001) and ethylene (Singh et al., 2000), which also exert significant effects on root development. The changes of other hormones contents (ZR, GA$_3$, ABA, and BR) were also detected in roots and leaves of transgenic plants and WT under two N levels, in previous report, Tian et al. (2005) also discovered that cytokinin concentrations in roots enhanced with increasing NO$_3^−$ supply. Therefore, it is supposed that IAA might synergistically interact with ZR, GA$_3$, ABA, and BR to affect the growth of cassava plants. And further study is required to elucidate the interaction among these hormones on NO$_3^−$ mediated cassava growth.

In summary, MeNPF4.5 is mainly expressed in cassava roots, and its expression is induced by NO$_3^−$. Overexpressing MeNPF4.5 in cassava promoted growth and improved the NUE and yield. The main reasons for these effects may be increased photosynthesis and N metabolism enzyme activity. Down-regulation of MeNPF4.5 expression resulted in inhibition of cassava growth and reduction of NUE, causing a decrease in biomass and yield. Overall, our study reveals the role of MeNPF4.5 in N uptake and utilization, which has not been previously reported, and shows that this NRT may have potential breeding value.
