Nuclear Receptor NR4A2 Orchestrates Th17 Cell-Mediated Autoimmune Inflammation via IL-21 Signalling

Ben J. E. Raveney, Shinji Oki, Takashi Yamamura

Department of Immunology, National Institute of Neuroscience, National Center of Neurology and Psychiatry, Kodaira, Tokyo, Japan

Abstract

IL-17-producing CD4+ T helper 17 (Th17) cells are pathogenic in a range of human autoimmune diseases and corresponding animal models. We now demonstrate that such T cells infiltrating the target organ during the induction of experimental autoimmune encephalomyelitis (EAE) and experimental autoimmune uveoretinitis (EAU) specifically express NR4A2. Further, we critically reveal a role of NR4A2 in Th17 cell functions and Th17 cell-driven autoimmune diseases. When NR4A2 expression was blocked with siRNA, full Th17 differentiation was prevented both in vitro and in vivo; although cells expressed the master Th17 regulator, RORγt, they expressed reduced levels of IL-23R and were unable to produce IL-17 and IL-21. Notably, Th17 differentiation in the absence of NR4A2 was restored by exogenous IL-21, indicating that NR4A2 controls full maturation of Th17 cells via autocrine IL-21 signalling. Preventing NR4A2 expression in vivo by systemic treatment with NR4A2-specific siRNA also reduced Th17 effector responses and furthermore protected mice from EAE induction. In addition, the lack of disease was associated with a reduction in autocrine IL-21 production and IL-23R expression. Similar modulation of NR4A2 expression was also effective as an intervention, reversing established autoimmune responses and ameliorating clinical disease symptoms. Thus, NR4A2 appears to control Th17 differentiation and so plays an essential role in the development of Th17-mediated autoimmune disease. As NR4A2 is also upregulated during human autoimmune disease, targeting NR4A2 may provide a new therapeutic approach in treating autoimmune disease.

Introduction

T helper (Th) cells responding to self-antigens generate pathogenic inflammatory responses in target organs, leading to local damage and so generate organ-specific autoimmune diseases. It was previously thought that CD4+ interferon (IFN)-γ-secreting Th1 cells were critical in inducing autoimmune damage to the central nervous system (CNS) in human multiple sclerosis (MS) and its animal model, experimental autoimmune encephalomyelitis (EAE) [1]. However, the discovery of pathogenic IL-17-secreting Th17 cells as a separate cell lineage opened the door to new research directions towards understanding the development of autoimmune inflammation [2–4]. It is now understood that both Th1 and Th17 cells mediate autoimmune responses in rodents [5–8] as well as in humans [9,10]. Regarding the development of EAE, it has recently been proposed that the major proportion of T cells producing inflammatory cytokines, including IFN-γ, may in fact be T cells that had previously produced IL-17 [11]. Thus, manipulation of Th17 cells might prove effective in controlling complex autoimmune disease processes involving both Th1 and Th17 cells.

Naïve CD4+ T cells differentiate into Th1 cells under the influence of IL-12, whereas TGF-β in combination with IL-6 is appreciated as the classical Th17-differentiating cytokine milieu [12,13]. Recently, however, Th17 differentiation pathways that do not depend on IL-6 or TGF-β have also been described [14–16]. In contrast, in vivo studies demonstrate that IL-23 plays a critical role in promoting generation of Th17 cells. Indeed, Th17-mediated autoimmune disease is greatly reduced or prevented in the absence of IL-23 signalling [17,18].

NR4A2, also known as Nur1, is an orphan nuclear receptor [19–22], and its function in dopaminergic neuron signalling has been widely known. Increasing evidence suggests the role of NR4A2 in inflammatory responses during arthritis and psoriasis [23,24], and NR4A2 may also serve as a regulatory element for reducing immune-mediated tissue damage [25]. We have previously reported that NR4A2 is among the genes expressed by circulating T cells that are highly upregulated in patients with multiple sclerosis (MS) and that NR4A2 is also induced in T cells during rodent EAE [26,27]. We also demonstrated that forced NR4A2 expression enhanced non-specific production of Th1 and Th17 cytokines although further confirmation was needed to confirm the role of NR4A2 in T cell functions.

In this study, we firstly show that NR4A2 is strikingly upregulated by IL-17-secreting Th17 cells infiltrating the target organ of EAE and experimental autoimmune uveoretinitis (EAU), the murine model of posterior uveitis. Using siRNA knockdown techniques, we demonstrate that NR4A2 is dispensable for...
induction of the Th17 cell transcription factor RORγt in T cells, but is critically required for the in vitro generation of fully functional Th17 cells capable of producing IL-17 and IL-21, and expressing the IL-23 receptor (IL-23R). Notably, addition of exogenous IL-21 was able to circumvent the requirement for NR4A2 in Th17 differentiation, and restore the expression of IL-23R and IL-17. Furthermore, NR4A2 knockdown in vivo by injection of NR4A2 siRNA either before or after the onset of CNS infiltration ameliorated EAE. Taken together, these data suggest that T cell NR4A2 expression is a hallmark of Th17 cell-mediated pathology and show for the first time that systemic injection of a NR4A2-targeting drug may be a treatment option for Th17-cell mediated diseases.

Materials and Methods

Animals and EAE/EAU Induction

Female C57BL/6j mice (CLEA Laboratory Animal Corp., Tokyo, Japan) aged 8–10 weeks were maintained in specific pathogen–free conditions in accordance with institutional guidelines. This study and all protocols used were approved by the Committee for Small Animal Research and Animal Welfare (National Center of Neurology and Psychiatry). Procedures were carried out under institutional guidelines and all efforts were made to minimize animal suffering. For EAE induction, mice were injected subcutaneously with 100 μg MOG35-55 peptide (synthesized by Toray Research Center, Tokyo, Japan) and 1 mg heat-killed mycobacterium tuberculosis H37RA emulsified in complete Freund’s adjuvant (Difco, KS, USA). 200 ng Pertussis toxin (List Biological Laboratories, USA) was injected intraperitoneally (i.p.) on days 0 and 2 after immunization. EAE was clinically scored daily (0, no clinical signs; 1, partial tail paralysis; 2, flaccid tail; 3, hind limb paralysis; 4, total hind limb paralysis; 5, hind and daily (0, no clinical signs; 1, partial tail paralysis; 2, flaccid tail; 3, hind limb paralysis; 4, total hind limb paralysis; 5, hind and

Cell Culture

Culture media was DMEM supplemented with 10% FCS, 2 mM L-glutamine, 100 U/ml penicillin-streptomycin, and 50 μM 2-Mercaptoethanol (all Invitrogen). Where indicated, cells were activated with 2 μg/ml immobilized CD3-specific mAb (2C-11) and 1 μg/ml CD28-specific mAb (BD Pharmingen, Tokyo, Japan). Polarizing conditions were as follows: Th1, +10 ng/ml IL-12 (PeproTech, London, UK) and 10 μg/ml IL-4-specific mAb (BD Pharmingen, Tokyo, Japan); Th17, 3 ng/ml TGF-β (R & D Systems, Minneapolis, USA), 20 ng/ml IL-6 (PeproTech), 20 ng/ml IL-23 (R & D Systems), 10 μg/ml IFN-γ specific mAb, and 10 μg/ml IL-4 specific mAb.

Assessment of Cell Function

Cytokine concentrations in supernatants were measured by ELISA as follows: IL-17 using a mouse IL-17 DuoSet (R&D Systems), IL-21 using an IL-21 MaxiSet kit (Biologend, San Diego, USA), and IFN-γ using a mouse IFN-γ ELISA antibody pair (BD Biosciences). Other cytokines were assessed using a FlowCytometric cytokine bead array (Bender MedSystems, Vienna, Austria) according to the manufacturer’s instructions. Proliferation was determined by incubation with [3H]-thymidine (1 μCi/well) for the final 12 hours of culture and incorporation of radioactivity was assessed with a β-1205 counter (Pharmacia Biotech, Freiburg, Germany). For intracellular staining, cells were restimulated with 5 ng/ml PMA + 500 ng/ml ionomycin (both Sigma-Aldrich, Tokyo, Japan) in the presence of Golgi Stop (BD Biosciences) for 5 hours, before surface staining and fixing/ intracellular staining using a Foxp3 staining kit (eBioscience, Vienna, Austria) according to the manufacturer’s instructions. Antibodies were sourced from BioLegend (San Diego, USA), except for anti-cytoplasmic IL-23R (Millipore, Tokyo, Japan).

RNA Extraction and Quantitative RT-PCR

Total RNA was extracted from cell populations using an RNeasy Mini Kit or FastLane kit (Qiagen, Maryland, USA) according to the manufacturer’s instructions. cDNA was prepared using a first-strand cDNA Kit (Takara). Quantitative real time PCR was performed with a Light Cycler-FastStart DNA Master SYBR Green I kit using a LightCycler instrument (Roche Diagnostics, Tokyo, Japan) or with a Power SYBR green master
NR4A2 Expression is Not Detected in STZ-induced Diabetes or Following OVA Immunization

We next measured NR4A2 expression in T cells from streptozotocin (STZ)-induced autoimmune diabetes [35], in which autoimmune Th1 cells but not Th17 cells are thought to play a pathogenic role [31]. Repeated administration of low-dose streptozotocin (STZ) induced anti-pancreatic autoimmunity accompanied with clinical diabetes by day 10 (Fig. S1C). Consistent with a previous report [33], splenocytes as well as pancreata-infiltrating T cells produced raised levels of IFN-γ, but not IL-17, after in vitro stimulation (Fig. S1D). Unlike CNS-infiltrating T cells in EAE, NR4A2 upregulation was not detected amongst pancreata-infiltrating T cells (Fig. 1F). We also examined blood T cells from these mice and detected no NR4A2 upregulation at any time (Fig. S1E). Furthermore, we examined if NR4A2 upregulation might be induced by active immunization with any antigen in CFA. However, immunization with OVA in CFA, using the same protocol for inducing EAE with MOG peptide, did not lead to NR4A2 upregulation.

NR4A2 Expression is Required for IL-17 Production by RORγt+ T cells

As NR4A2 expression appeared to be associated with IL-17-secreting pathogenic T cells, we speculated that NR4A2 might function in the process of Th17 cell differentiation. Using NR4A2-specific siRNA, we investigated in vitro if CD4+ T cells differentiate normally into Th1 or Th17 cells in the absence of NR4A2 regulation. Activation of T cells leads to a rapid and transient upregulation of NR4A2 that could be prevented by transfection with NR4A2 siRNA (Fig. S2A). When NR4A2 expression was silenced in this manner, naïve CD4+ T cells were able to differentiate into IFN-γ-producing cells (Fig. 2A&C), excluding a requirement for NR4A2 in Th1 cell development. However, blocking NR4A2 upregulation with siRNA greatly reduced Th17 differentiation driven by any concentrations of TGF-β, as assessed by an increase in IFN-γ:cytokine production (Fig. 2B&C), instead there was an increase in IFN-γ-secretion T cells. We also noted that NR4A2 knockdown did not significantly reduce the proliferation of CD4+ T cells under any polarizing conditions tested (Fig. S2B), indicating that NR4A2-specific siRNA is unlikely to prevent IL-17 production in the absence of NR4A2, T cells did upregulate RORγt, the hallmark transcription factor of Th17 cells, to levels comparable to fully functional Th17 cells (Fig. 2D).

Lack of IL-17 in the Absence of NR4A2 does not Result from the Action of Foxp3

A previous study has described a failure of RORγt-expressing Th17 cells to secrete IL-17 resulting from a direct inhibitory interaction between RORγt and the transcription factor Foxp3 [36]. To examine if a similar mechanism, involving Foxp3, is applicable to interpreting our results, we measured the level of Foxp3 expression during NR4A2 knockdown. NR4A2 siRNA did not enhance but reduced Foxp3 expression in both Th17 (TGF-β+IL-6) and regulatory T cell (TGF-β alone) differentiating conditions (Fig. S3A). This finding is consistent with a recent report on a role of NR4A2 for inducing Foxp3 in regulatory T cells [37]. Furthermore, we tested if NR4A2 ablation by siRNA treatment was still effective in preventing IL-17 production when Foxp3 expression was blocked. To do this, we used Foxp3-specific siRNA to prevent Foxp3 expression in T cells that also received either control or NR4A2-specific siRNA. Foxp3 knockdown did not restore IL-17 production in the absence of NR4A2 (Fig. S3B).
NR4A2 Controls the IL-21-initiated Phase of Th17 Differentiation

RORγt expression is required for generation of fully functional Th17 cells. However, when upregulation of NR4A2 is prevented, Th17-polarized RORγt+ T cells do not acquire the ability to produce IL-17 (Fig. 2). A possible scenario is that RORγt regulation is an early event in Th17 differentiation [38], whereas later induction of NR4A2 is critical for inducing signals that promote IL-17 production. IL-21-deficient or IL-21R-deficient T cells resemble NR4A2-deficient T cells in that they express RORγt but do not produce IL-17 under Th17 polarizing condition [4,39]. Thus, we suspected that NR4A2 expression might control IL-17 production via autocrine IL-21 signalling. IL-21 is produced during early Th17 cell differentiation and then acts in an autocrine manner to induce IL-23R upregulation by Th17 cells [38,40]; the subsequent action of IL-23 produced by myeloid cells then enhances and stabilizes the Th17 cell phenotype via IL-21/IL-23R pathway, we reintroduced this pathway by adding exogenous IL-21 to cultures. Critically, the presence of exogenous IL-21 restored IL-17 secretion by T cells stimulated under Th17 polarizing conditions despite the lack of NR4A2 (Fig. 4A). Additionally, NR4A2-knocked down Th17 cells cultured with IL-21 also expressed equivalent levels of IL-23R to the control Th17 cells (Fig. 4B).

NR4A2 Controls the Severity of EAE

Next we tested if NR4A2 also controlled pathogenic Th17 responses in EAE. Administration of NR4A2-specific siRNA on the day of EAE induction was effective at preventing NR4A2 expression by CNS-infiltrating T cells (Fig. S4A). Such systemic blockade of NR4A2 suppressed the onset of clinical EAE (Fig. 5A), accompanied by a reduced ability of CNS-infiltrating CD4+ T cells to produce IL-17 (Fig. 2). A possible scenario is that RORγt expression is required for generation of fully functional Th17 cells, and the underlying mechanism is independent of RORγt but do not produce IL-17 under Th17 polarizing conditions. Thus, NR4A2 appears to be required for IL-17 production by Th17 cells, and the underlying mechanism is independent of RORγt and Foxp3.
Figure 2. NR4A2 knockdown prevents IL-17 secretion but not RORγt upregulation. Naïve CD4+ T cells were transfected by electroporation with NR4A2-specific siRNA or scrambled control siRNA. Cells were then activated with 5 μg/ml plate-bound CD3-specific mAb and 0.5 μg/ml soluble CD28-specific mAb. A: IFN-γ production by cells activated in the presence or absence of 10 ng/ml IL-12 after 96 hours of culture. B: IL-17 production.
by cells activated in the presence of 20 ng/ml IL-6, 20 ng/ml IL-23, and TGF-β at a range of concentrations after 96 hours of culture. Significant differences between control and NR4A2 siRNA-treatments were tested with a student’s t-test, *p<0.05. C: IL-17 and IFN-γ intracellular cytokine staining for transfected T cells (control siRNA, left plots; NR4A2 siRNA, right plots) cultured for 96 hours in the presence of 10 ng/ml IL-12 (Th1 conditions, top row plots) or 20 ng/ml IL-6, 20 ng/ml IL-23, and 3 ng/ml TGF-β (Th17 conditions, bottom row plots). D: RORγt RNA expression as measured by real time PCR by activated T cells cultured under Th17 polarizing conditions at a range of timepoints. Data are representative of 5 independent experiments.

doi:10.1371/journal.pone.0056595.g002

cells to secrete IL-17 but not IFN-γ (Fig. 5B) when restimulated with the immunizing peptide. NR4A2 siRNA treatment also led to a lower proportion of T cells in the target organ that produced IL-17 upon non-specific restimulation during early timepoints (summarized in Fig. 5C; representative data, Fig. S4B). However, we observed that the effect of NR4A2 siRNA is not persistent, and the mice showed signs of late onset EAE after day 21 (Fig. 5A) accompanied by an increase in the proportion of IL-17+ T cells in the CNS (Fig. 5C). Since collagen-stabilized siRNA maintains its suppressive activity in vivo for approximately three weeks [43], the

Figure 3. Absence of NR4A2 is associated with a lack of IL-21 production by Th17 cells. Naïve CD4+ T cells were transfected by electroporation with NR4A2-specific siRNA or scrambled control siRNA and were activated with 5 μg/ml plate-bound CD3-specific mAb and 0.5 μg/ml soluble CD28-specific mAb in the presence of 20 ng/ml IL-6, 20 ng/ml IL-23, and 3 ng/ml TGF-β. A: RNA levels of IL-21, IL-23R, and IL-17 were quantified by real time PCR at the indicated timepoints following activation. Data are representative of 3 independent experiments. B: IL-21 supernatant concentration was measured by ELISA at 96 hours. Data are representative of 3 independent experiments. *p<0.05. C: RNA expression of c-maf quantified by real time PCR. doi:10.1371/journal.pone.0056595.g003
later onset of EAE may reflect the reduced potency of the siRNA. We then tested the effect of injection of NR4A2 siRNA at a later timepoint. Interestingly, when the NR4A2 siRNA was given on day 10 post-EAE induction, clinical EAE was greatly reduced, and unlike treatment at day 0, no increase in disease was observed after day 20 (Fig. 5D). These results indicate that NR4A2 targeting

Figure 4. Exogenous IL-21 restores IL-17 production in the absence of NR4A2. Naïve CD4\(^+\) T cells were transfected by electroporation with NR4A2-specific siRNA or scrambled control siRNA and were activated with 5 μg/ml plate-bound CD3-specific mAb and 0.5 μg/ml soluble CD28-specific mAb in the presence of 20 ng/ml IL-6, 20 ng/ml IL-23, and 3 ng/ml TGF-β. To some wells, recombinant IL-21 was added as indicated. A: IL-17 was measured in the supernatants of control or NR4A2 siRNA-treated T cells by ELISA after 96 hours of culture under Th17 polarizing conditions in the presence or absence of IL-21 at the indicated concentrations. *p<0.05. Data are representative of 3 independent experiments. B: IL-23R expression was assessed by intracellular flow cytometric staining after 96 hours of culture under Th17 polarizing conditions in the presence (right plots) or absence (left plots) of 100 pg/ml recombinant IL-21 for control siRNA-treated T cells (top) and NR4A2 siRNA-treated T cells (bottom row). Data are representative of 2 independent experiments.

doi:10.1371/journal.pone.0056595.g004
siRNA is not only preventative, but also therapeutic against the development of EAE. Furthermore, the CNS-infiltrating T cells also showed reduced expression of IL-21 and IL-23R (Fig. 5E&F), reminiscent of the in vitro blocking of NR4A2 during Th17 cell differentiation. Based on these data, we suggest that NR4A2 is a key factor for Th17 differentiation in vivo during the initiation of autoimmune responses via its control of IL-21 and IL-23R expression.

Discussion

In this study, we demonstrate that the orphan nuclear receptor NR4A2 is highly expressed by IL-17-secreting T cells infiltrating the target organ of EAE and EAU. When upregulation of NR4A2 was prevented in vitro, Th17-polarizing T cells expressing RORγt did not further differentiate into mature Th17 cells capable of producing IL-21 and IL-17. This inhibition of Th17 cell differentiation was associated with disruption of autocrine IL-21 signalling. In vitro analysis showed that adding exogenous IL-21 restored the ability of the NR4A2 knocked-down Th17 cells to express IL-23R and produce IL-17. Furthermore, in vivo injection of NR4A2 siRNA prevented the development of EAE by specifically inhibiting Th17 cell production of IL-17, but not affecting Th1 cells. Based on these findings, we propose that NR4A2 has direct effects on T cell pathogenicity or plays a critical role in continuous new Th17 differentiation and thus it orchestrates effector functions of Th17 cells in mediating autoimmune diseases.

Reagents that dampen the function of Th17 cells are of practical interest in clinical settings. Indeed, an IL-17A-specific antibody was efficacious in clinical trials of human psoriasis, uveitis, and rheumatoid arthritis [44]. Although the effects of IL-17 blockade on EAE appear to be only modest [45,46], clinical trials are currently in progress to test IL-17A-specific antibody treatment in MS patients. As Th17 cells probably generate a range of proinflammatory cytokines, it is debatable how effective a therapy targeting a single cytokine may prove. NR4A2 appears to control various molecules regulated by IL-21 signalling and therefore a drug targeting NR4A2 may prove more effective than an antibody against a single cytokine.

We previously described that forced expression of NR4A2 in resting T cells led to a modest increase in IFN-γ production following nonspecific stimulation and suggested that NR4A2 might be involved in both Th1 and Th17 cell responses [27]. In contrast, we here reveal that only Th17 cells were found to express NR4A2 in the lesions of EAE, implying that NR4A2 plays a more important role in Th17 cells than in Th1 cells during autoimmune inflammation. However, it is not surprising to see a reduced IFN-γ production in NR4A2 knocked-down T cells in vitro (Fig. 2A), since IL-21 has potentials to modulate IFN-γ production under particular conditions [47]. An unexpected report was that the absence of NR4A2 led to increased expression of IFN-γ [37]. The authors argued that the increased production of IFN-γ was due to reduced activity of Foxp3+ regulatory T cells that are also dependent on NR4A2 [37]. However, this report does not contradict with our results, because in our in vitro experiments, we have explicitly removed regulatory T cells from the starting cell populations.

In agreement with previous studies [17,48], our results showed that autocrine IL-21 production would promote IL-23R expression and subsequent production of IL-17 during Th17 cell

![Figure 5. Systemic administration of NR4A2-specific siRNA reduces EAE severity.](image-url) siRNA, either NR4A2-specific or control, was stabilized in a collagen matrix and administered i.v. to groups of C57BL/6 mice at the time of EAE induction. EAE was scored clinically (A) and at day 15 post-EAE induction, production of IL-17 and IFN-γ by CNS-infiltrating leukocytes restimulated with 20 μg/ml MOG peptide for 96 hours were assessed by ELISA (B). CNS-infiltrating T cells were also assessed for IL-17 production at a range of timepoints by intracellular flow cytometry (C). Data are representative of 3 independent experiments. Control or NR4A2-specific siRNA was applied to MOG-immunized mice at day 10 post-disease induction and disease was scored clinically (D). Timepoints correspond to a minimum of 5 animals and data are representative of 2 independent experiments. IL-21 and IL-23R expressions amongst CNS-infiltrating T cells were measured by real time PCR (E&F). Data are representative of 2 independent experiments. Clinical scores in panels A) and D) were tested with a two-way ANOVA test. *p<0.01, **p<0.001.

doi:10.1371/journal.pone.0056595.g005
NR4A2 Controls Th17-Mediated Autoimmunity

differentiation. When NR4A2 upregulation was blocked by siRNA treatment, the production of IL-17 was greatly reduced, although RORγt expression was maintained, but exogenously added IL-21 restored IL-17 and IL-23R expression. Furthermore, NR4A2 also appeared to be required for the induction of the transcription factor that controls IL-21 secretion following Th17 differentiation, c-maf [41]. Moreover, lack of NR4A2 had little effect on RORγt expression, implying that this transcription factor is not associated with an IL-21-related pathway. It is interesting that IL-22 production is also maintained in the absence of NR4A2, despite the lack of IL-23R, suggesting that this cytokine could be produced via IL-23-independent pathways. TGF-β signals usually inhibit IL-22 production [16], however it is conceivable that these inhibitory signals are ineffective without NR4A2, thus allowing IL-22 secretion in the absence of increased IL-23R expression. Thus, NR4A2 modulation of Th17 cells may be limited to a role in the c-maf/IL-21 pathway, which ultimately controls IL-23R regulation and subsequent signalling. Given the critical role of IL-23 during pathogenic Th17 cell differentiation [16], the ability of NR4A2 siRNA to affect IL-23R expression by inhibiting IL-21 production cannot be ignored. It has been shown that IL-21 can drive Th17 differentiation [49] and thus enhance the initiation phase of EAE [50]. Therefore, the NR4A2-IL-21 pathway is particularly interesting as a therapeutic target. On the other hand, although a report claims that IL-21 is essential for Th17 differentiation [39], other reports showed Th17 differentiation in the absence of IL-21, albeit at a reduced level [14], and IL-17 production and EAE induction were not entirely blocked without IL-21 autocrine signals [51,52]. The discrepancy regarding the role of IL-21 in Th17 cell induction remains to be fully understood and it is possible that absence of IL-21 signalling in gene knockout mice may be compensated by an alternative cytokine signalling pathway. However, our data may be explained by direct effects of NR4A2 on IL-23R upregulation as well as on the c-maf/IL-21 pathway.

In conclusion, our findings highlight the application of siRNA in vivo to modulate immunologic pathways that generate pathogenic autoimmune responses. Furthermore, our discovery of the key role of NR4A2 signalling in Th17 differentiation and our identification of the involvement of NR4A2 in generating autoimmune response in vivo suggest a new target for intervention in Th17-mediated autoimmune disease. This view is supported by our direct demonstration that manipulation of NR4A2 expression by siRNA treatment in established disease ameliorated clinical symptoms. Thus, future therapies targeting NR4A2 may prove highly effective in treating particular autoimmune diseases.

Supporting Information

Figure S1 EAE or EAU was induced in C57BL/6 mice by immunization with MOG35–55 or IRBP1–20 peptide in CFA. EAE was scored clinically (A). CD4+ T cells were purified from the retina on the indicated days, and EAU disease severity was evaluated by flow cytometric enumeration of ocular infiltrates for EAU (B). Timepoints correspond to a minimum of 5 animals and data are representative of 3 independent experiments. A group of C57BL/6 mice received a low dose of STZ daily for 5 days. Clinical diabetes was tested by measurement of urine glucose level, with diabetes confirmed by consecutive urine glucose result of greater than $\geq 300$ mg/dl (C). Plot C shows percentage diabetes. Other groups of C57BL/6 mice were immunized with peptides in CFA plus PTX either OVA323–339 (OVA/CFA) or MOG35–55 (MOG/CFA). On day 22, splenocytes and leukocytes isolated from the relevant target organ (ND, OVA/CFA; CNS, EAE; pancreas, STZ) were restimulated with 20 mg/ml of the immunizing peptide, or with soluble anti-CD3 (for STZ); after 96 hours, IL-17 and IFN-γ were measured in supernatants by ELISA (D); NR4A2 expression by blood T cells was also measured at a range of timepoints (E). Timepoints correspond to a minimum of 5 animals and data are representative of 2 independent experiments. (TIF)

Figure S2 Naïve CD4+ T cells were transfected by electroporation with NR4A2-specific siRNA or scrambled control siRNA. Cells were then activated with 5 µg/ml plate-bound CD3-specific mAb and 0.5 µg/ml soluble CD28-specific mAb in the presence of 20 ng/ml IL-6, 20 ng/ml IL-23, and 3 ng/ml TGF-β. NR4A2 expression was assessed at a range of timepoints by RT PCR (A). Data are representative of 5 independent experiments. Cell proliferation of transfected cells following anti-CD3/anti-CD28 stimulation in the presence of Thr (±10 ng/ml IL-12), Th17 (±20 ng/ml IL-6, 20 ng/ml IL-23, and 3 ng/ml TGF-β), or in the absence of polarizing cytokines was measured at 96 hours by the incorporation of $^3$H-thymidine. Data are representative of 2 independent experiments. (TIF)

Figure S3 Naïve CD4+ T cells transfected by electroporation with NR4A2-specific siRNA or scrambled control siRNA were activated with plate-bound CD3-specific mAb and soluble CD28-specific mAb in the presence of 10 µg/ml IFN-γ-specific and IL-4-specific mAb, with either 20 ng/ml IL-6, 2 ng/ml TGF-β (IL-6+ TGF-β) or with 10 ng/ml TGF-β (TGF-β), Fsp3 expression at 96 hours as measured by real time PCR is shown in plot A. Data shown represent averages of 4 independent experiments. Naïve CD4+ T cells were transfected by electroporation with 2 siRNAs: either Fsp3-specific siRNA or relevant scrambled control siRNA and with either NR4A2-specific siRNA or relevant scrambled control siRNA. This yielded 4 cell types: 1) Fsp3 control/NR4A2 control (C/C); 2) Fsp3 control/NR4A2 siRNA (C/N); 3) Fsp3 siRNA/NR4A2 control (F/C); and 4) Fsp3 siRNA/NR4A2 siRNA (F/N). Cells were then activated with plate-bound CD3-specific mAb and soluble CD28-specific mAb in the presence of 10 µg/ml IFN-γ-specific and IL-4-specific mAb with either 20 ng/ml IL-6, 2 ng/ml TGF-β (IL-6+ TGF-β) or with 10 ng/ml TGF-β (TGF-β). Plot B shows IL-17 production from each of 4 siRNA-treated cell types at 96 hours as measured by ELISA. Data are representative of 2 independent experiments. siRNA, either NR4A2-specific or control, was stabilized in a collagen matrix and administered i.v. to groups of C57BL/6 mice at the time of EAE induction. At the indicated timepoints, CNS-infiltrating T cells were FACSc-sorted and NR4A2 expression was assessed by RT PCR (A). CNS-infiltrating leukocytes from day 15 post-EAE induction from control or NR4A2 siRNA-treated mice were restimulated with PMA/ionomycin for 5 hours, and IL-17 and IFN-γ production were visualized by intracellular flow cytometric staining (B). Data are representative of 3 independent experiments (TIF)

Figure S4 siRNA, either NR4A2-specific or control, was stabilized in a collagen matrix and administered i.v. to groups of C57BL/6 mice at the time of EAE induction. At the indicated timepoints, CNS-infiltrating T cells were FACSc-sorted and NR4A2 expression was assessed by RT PCR (A). CNS-infiltrating leukocytes from day 15 post-EAE induction from control or NR4A2 siRNA-treated mice were restimulated with PMA/ionomycin for 5 hours, and IL-17 and IFN-γ production were visualized by intracellular flow cytometric staining (B). Data are representative of 3 independent experiments (TIF)
were visualized by intracellular flow cytometric staining (B). Data are representative of 3 independent experiments. (TIF)
