Classification of the $Z_2Z_4$-Linear Hadamard Codes and Their Automorphism Groups

Denis S. Krotov and Mercè Villanueva

Abstract—A $Z_2Z_4$-linear Hadamard code of length $\alpha + 2\beta = 2^n$ is a binary Hadamard code which is the Gray map image of a $Z_2Z_4$-additive code with $\alpha$ binary coordinates and $\beta$ quaternary coordinates. It is known that there are exactly $\lfloor \frac{2^n}{2} \rfloor$ and $\lceil \frac{2^n}{2} \rceil$ nonequivalent $Z_2Z_4$-linear Hadamard codes of length $2^n$, with $\alpha = 0$ and $\alpha \neq 0$, respectively, for all $t \geq 3$. In this paper, it is shown that each $Z_2Z_4$-linear Hadamard code with $\alpha = 0$ is equivalent to a $Z_2Z_4$-linear Hadamard code with $\alpha \neq 0$, so there are only $\lceil \frac{2^n}{2} \rceil$ nonequivalent $Z_2Z_4$-linear Hadamard codes of length $2^n$. Moreover, the order of the monomial automorphism group for the $Z_2Z_4$-additive Hadamard codes and the permutation automorphism group of the corresponding $Z_2Z_4$-linear Hadamard codes are given.

Index Terms—Hadamard codes, $Z_2Z_4$-linear codes, additive codes, automorphism group

I. INTRODUCTION

Let $Z_2$ and $Z_4$ be the rings of integers modulo 2 and modulo 4, respectively. Let $Z_2^n$ be the set of all binary vectors of length $n$ and let $Z_4^n$ be the set of all quaternary vectors of length $n$. For a vector $x = (x_1, \ldots, x_n) \in Z_2^n$ and a set $I \subseteq \{1, \ldots, n\}$, we denote by $x|_I$ the vector restricted to the coordinates in $I$.

Any nonempty subset $C$ of $Z_2^n$ is a binary code and a subgroup of $Z_2^n$ is called a binary linear code. Similarly, any nonempty subset $C$ of $Z_4^n$ is a quaternary code and a subgroup of $Z_4^n$ is called a quaternary linear code. Let $C$ be a quaternary linear code. Since $C$ is a subgroup of $Z_4^n$, it is isomorphic to an Abelian group $Z_2^\alpha \times Z_4^\beta$, for some $\alpha$ and $\beta$, and we say that $C$ is of type $2^\alpha 4^\beta$ as a group. Quaternary codes can be seen as binary codes under the usual Gray map defined as $\varphi(0) = (0, 0)$, $\varphi(1) = (0, 1)$, $\varphi(2) = (1, 1)$, $\varphi(3) = (1, 0)$ in each coordinate. If $C$ is a quaternary linear code, then the binary code $\varphi(C)$ is called a $Z_4$-linear code.

Additive codes were first defined by Delsarte in 1973 as subgroups of the underlying Abelian group in a translation association scheme [7], [8]. In the special case of a binary Hamming scheme, that is, when the underlying Abelian group is of order $2^n$, the additive codes coincide with the codes that are subgroups of $Z_2^n \times Z_2^n$. In order to distinguish them from additive codes over finite fields [3], they are called $Z_2Z_4$-additive codes [4]. Since $Z_2Z_4$-additive codes are subgroups of $Z_2^n \times Z_4^n$, they can be seen as a generalization of binary (when $\beta = 0$) and quaternary (when $\alpha = 0$) linear codes. As for quaternary linear codes, $Z_2Z_4$-additive codes can also be seen as binary codes by considering the extension of the usual Gray map: $\Phi : Z_2^n \times Z_4^n \rightarrow Z_2^n$, where $n = \alpha + 2\beta$, given by

$$\Phi(x, y) = (x, \varphi(y_1), \ldots, \varphi(y_\beta)) \quad \forall x \in Z_2^n, \forall y = (y_1, \ldots, y_\beta) \in Z_4^n.$$

If $C$ is a $Z_2Z_4$-additive code, $C' = \Phi(C)$ is called a $Z_2Z_4$-linear code. Moreover, a $Z_2Z_4$-additive code $C$ is also isomorphic to an Abelian group $Z_2^\gamma \times Z_4^\delta$, and we say that $C$ (or equivalently the corresponding $Z_2Z_4$-linear code $C = \Phi(C)$) is of type $(\alpha, \beta; \gamma, \delta)$.

Let $S_n$ be the symmetric group of permutations on the set $\{1, \ldots, n\}$, and let $\sigma \in S_n$ be the identity permutation. The group operation in $S_n$ is the function composition. The composition $\sigma_1\sigma_2$ maps any element $x$ to $\sigma_1(\sigma_2(x))$. A $\sigma \in S_n$ acts linearly on words of $Z_2^n$ or $Z_4^n$ by permuting the coordinates, $\sigma((c_1, \ldots, c_n)) = (c_{\sigma^{-1}(1)}, \ldots, c_{\sigma^{-1}(n)})$.

Let $C$ be a $Z_2Z_4$-additive code of type $(\alpha, \beta; \gamma, \delta)$. We can assign a permutation $\pi_x \in S_n$ to each codeword $x = (x_1, \ldots, x_n, x_1, \ldots, x_{2\beta}) \in C = \Phi(C)$, such that $\pi_x = \pi_1 \pi_2 \cdots \pi_{2^{\beta-1}}$, where

$$\pi_{ij} = \begin{cases} \text{id} & \text{if } (i, j) = (0, 0) \text{ or } (1, 1) \\ (i, j) & \text{otherwise.} \end{cases}$$

Given two codewords of $C$, $x = (x_1, x_1, \ldots, x_{2\beta})$ and $y = (y_1, y_1, \ldots, y_{2\beta})$, define $x \ast y = x + \pi_x(y)$. Then, we have that $(C, \ast)$ is an Abelian group [25], which is isomorphic to $(C, +)$, since

$$x \ast y = \left(x' + y', \varphi^{-1}(x_1, x_2) + \varphi^{-1}(y_1, y_2), \ldots, \varphi^{-1}(x_{2\beta-1}, x_{2\beta}) + \varphi^{-1}(y_{2\beta-1}, y_{2\beta})\right)$$

$$\ast \Phi(\Phi^{-1}(x) + \Phi^{-1}(y)).$$

There are $Z_2Z_4$-linear codes in several important classes of binary codes. For example, $Z_2Z_4$-linear perfect single error-correcting codes (or 1-perfect codes) are found in [25] and
fully characterized in \[6\]. Also, in subsequent papers \[15\], \[5\], \[16\], \[22\], \[23\], \(Z_2Z_4\)-linear extended perfect and Hadamard codes are studied and classified independently for \(\alpha = 0\) and \(\alpha \neq 0\). Finally, in \[24\], \[26\], \[20\], \(Z_2Z_4\)-linear Reed–Muller codes are also studied. Note that \(Z_2Z_4\)-linear codes have allowed to classify more binary nonlinear codes, giving them a structure as \(Z_2Z_4\)-additive codes.

A (binary) Hadamard code of length \(n\) is a binary code with \(2n\) codewords and minimum distance \(n/2\) \[19\]. The \(Z_2Z_4\)-additive codes that, under the Gray map, give a Hadamard code are called \(Z_2Z_4\)-additive Hadamard codes and the corresponding \(Z_2Z_4\)-linear codes are called \(Z_2Z_4\)-linear Hadamard codes, or just \(Z_4\)-linear Hadamard codes when \(\alpha = 0\). The classification of \(Z_2Z_4\)-linear Hadamard codes is given by the following results. For any integer \(t \geq 3\) and each \(\delta \in \{1, \ldots, \lfloor (t+1)/2 \rfloor \}\), there is a unique (up to equivalence) \(Z_4\)-linear Hadamard code of type \((0, 2^{-t-1}; t+1-2\delta, \delta)\), and all these codes are pairwise nonequivalent, except for \(\delta = 1\) and \(\delta = 2\), where the codes are equivalent to the linear Hadamard code, that is, the dual of the extended Hamming code \[16\]. Therefore, the number of nonequivalent \(Z_2\)-linear Hadamard codes of length \(2^t\) is \(\lfloor \frac{2^t}{2} \rfloor\) for all \(t \geq 3\). On the other hand, for any integer \(t \geq 3\) and each \(\delta \in \{0, \ldots, \lfloor t/2 \rfloor \}\), there is a unique (up to equivalence) \(Z_2Z_4\)-linear Hadamard code of type \((2^{-t-\delta}, 2^{-t-2\delta-1}; t+1-2\delta, \delta)\). All these codes are pairwise nonequivalent, except for \(\delta = 0\) and \(\delta = 1\), where the codes are equivalent to the linear Hadamard code \[5\]. Therefore, the number of nonequivalent \(Z_2Z_4\)-linear Hadamard codes of length \(2^t\) with \(\alpha \neq 0\) is \(\lfloor t/2 \rfloor\) for all \(t \geq 3\). In this paper, we show that any \(Z_4\)-linear Hadamard code is equivalent to a \(Z_2Z_4\)-linear Hadamard code with \(\alpha \neq 0\).

Two structural properties of binary codes are the rank and the dimension of the kernel. The rank of a code \(C\) is simply the dimension of the linear span, \(\langle C \rangle\), of \(C\). The kernel of a code \(C\) is defined as \(\text{Ker}(C) = \{ x \in Z_2^n \mid x + C = C \}\) \[2\]. If the all-zero vector belongs to \(C\), \(\text{Ker}(C)\) is a linear subcode of \(C\). In general, \(C\) can be written as the union of cosets of \(\text{Ker}(C)\), and \(\text{Ker}(C)\) is the largest linear code for which this is true \[2\]. The \(Z_2Z_4\)-linear Hadamard codes can also be classified using either the rank or the dimension of the kernel, as it is proven in \[16\], \[23\], where these parameters are computed.

Two \(Z_2Z_4\)-additive codes \(C_1\) and \(C_2\) both of type \((\alpha, \beta; \gamma, \delta)\) are said to be monomially equivalent, if one can be obtained from the other by permuting the coordinates and (if necessary) changing the signs of certain \(Z_4\) coordinates. Two \(Z_2Z_4\)-additive or \(Z_2Z_4\)-linear codes are said to be permutation equivalent if they differ only by a permutation of coordinates. The monomial automorphism group of a \(Z_2Z_4\)-additive code \(C\), denoted by \(\text{MAut}(C)\), is the group generated by all permutations and sign-changes of the \(Z_4\) coordinates that preserve the set of codewords of \(C\), while the permutation automorphism group of \(C\) or \(C = \Phi(C)\), denoted by \(\text{PAut}(C)\) or \(\text{Aut}(C)\), respectively, is the group generated by all permutations that preserve the set of codewords \[14\].

The permutation automorphism group of a binary code is also an invariant, so it can help in the classification of some families of binary codes. Moreover, the automorphism group can also be used in decoding algorithms and to describe some other properties like the weight distribution \[19\]. Chapter 8, §5 and Chapter 16, §9. The permutation automorphism group of \(Z_2Z_4\)-linear (extended) 1-perfect codes has been studied in \[22\], \[17\]. The permutation automorphism group of (nonlinear) binary 1-perfect codes has also been studied before, obtaining some partial results \[13\]. \[12\]. \[11\]. \[9\]. For \(Z_2Z_4\)-additive Hadamard codes with \(\alpha = 0\), the permutation automorphism group was characterized in \[21\], while the monomial automorphism group as well as the permutation automorphism group of the corresponding \(Z_2Z_4\)-linear codes had not been studied yet. In this paper, we completely solve this problem giving the structure and order of these two automorphism groups for any \(\alpha\).

The structure of the current paper is as follows. In Section \[III\] we suggest a new representation for the \(Z_2Z_4\)-linear Hadamard codes, separately for the cases \(\alpha = 0\) and \(\alpha \neq 0\), and prove that the \(Z_2Z_4\)-linear Hadamard codes of types \((0, n/2; \gamma, \delta)\) and \((\alpha, n/2 - \gamma + 2, 2, \delta - 1)\) with \(\alpha = n/2 - 1\) are permutation equivalent. In Sections \[III\] and \[IV\] we establish the structure and the order of the monomial automorphism group of the \(Z_2Z_4\)-additive Hadamard codes, for \(\alpha = 0\) and \(\alpha \neq 0\), respectively. In Sections \[V\] and \[VI\] we establish the structure and the order of the permutation automorphism group of the \(Z_2Z_4\)-linear Hadamard codes. The main results of the paper are Theorem \[1\] on the equivalence, Theorems \[2\] and \[3\] on the monomial automorphism group of the \(Z_2Z_4\)-additive Hadamard codes, Theorems \[4\] and \[5\] on the permutation automorphism group of the corresponding binary codes, and a representation of \(Z_2Z_4\)-linear Hadamard codes in Section \[II\].

II. Classification of \(Z_2Z_4\)-Linear Hadamard Codes

In \[16\] and \[5\], \(Z_2Z_4\)-linear Hadamard codes are classified independently for \(\alpha = 0\) and \(\alpha \neq 0\). In this section, we show that each \(Z_2Z_4\)-linear Hadamard code with \(\alpha = 0\) is equivalent to a \(Z_2Z_4\)-linear Hadamard code with \(\alpha \neq 0\), so there are only \(\lfloor \frac{n}{2} \rfloor\) nonequivalent \(Z_2Z_4\)-linear Hadamard codes of length \(2^n\).

We say that a function \(f\) from \(Z_2^n \times Z_4^n\) to \(Z_2^n \times Z_4^n\) is affine if \(f(0) - f(x) - f(y) + f(x+y) = 0\) for every \(x\) and \(y\) from \(Z_2^n \times Z_4^n\) (here and in what follows, \(0\) denotes the all-zero vector). Equivalently, \(f(\cdot) - f(0)\) is a linear function, i.e., a group homomorphism. Let \(B = B_{\gamma, \delta}\) be the set of all affine functions from \(Z_2^n \times Z_4^n\) to \(Z_4^n\). These \(Z_4^n\)-valued functions on \(Z_2^n \times Z_4^n\) can be considered as words of length \(2^\gamma + 2^\delta\) over \(Z_4^n\). Denote \(B_{\gamma, \delta} = \{ x : Z_2^n \times Z_4^n \rightarrow Z_4^n | x(\cdot) = \varphi(f(\cdot)) \text{ for some } f \in B \}\).

Lemma \[1\]: \(B_{\gamma, \delta}\) is a \(Z_4^n\)-linear Hadamard code of length \(n = 2^{\gamma+2^\delta+1}\) and type \((0, n/2; \gamma, \delta)\), where \(\delta = \delta + 1\).

Proof: There are \(4 \cdot 2^{\gamma} \cdot 4^\delta = 2n\) affine functions in \(B\). The set \(B\) is closed under the addition over \(Z_4^n\); so after applying the Gray map, \(B_{\gamma, \delta}\) is a \(Z_4^n\)-linear code of length \(2^{\gamma+2^\delta} \cdot 2 = n\). Clearly, the minimum Hamming distance is \(n/2\).
Define the function $\varphi^+ : Z_4 \to \{0, 1\}$ by $\varphi^+(0) = \varphi^+(3) = 0$, $\varphi^+(1) = \varphi^+(2) = 1$. Again, the $Z_2^d$-valued or $Z_4$-valued functions on $Z_2^d \times Z_4^d$ can be considered as words of length $2^d + 2d$ over $Z_2$ or $Z_4$, respectively. Let $A$ be the set of all affine functions $f$ from $Z_2^d \times Z_4^d$ to $Z_4$ that map the all-zero vector to 0 or 2: $f(\overline{0}) \in \{0, 2\}$. Denote $C_{\gamma, \delta} = \{ h : Z_2^d \times Z_4^d \to Z_4 | \ h(\cdot) = \varphi^+(f(\cdot))$ for some $f \in A$.

**Lemma 2:** $C_{\gamma, \delta}$ is a $Z_2^d \times Z_4^d$-linear Hadamard code of length $n = 2^d + 2d$ and type $(\alpha, \gamma, \delta)$, where $\gamma = \gamma + 1$, $\alpha = 2^d + \delta$ corresponding to the elements of order at most 2 of $Z_2^d \times Z_4^d$, and $\beta = 2^d + 3 \delta - 1 (2d - 1)$ corresponding to the pairs of opposite elements of order 4.

**Proof:** There are $2 \cdot 2^d \cdot 4^d = 2n$ affine functions in $A$. The set $A$ is closed under the addition over $Z_4$; so the Gray map image $A = \Phi(A)$ can also be considered as a $Z_2^d \times Z_4^d$-linear code with $2^d + 2d$ coordinates over $Z_4$, which correspond to the elements of order at most 2 of $Z_2^d \times Z_4^d$.

Now, we will see that the code $C$ can be obtained from $C_{\gamma, \delta}$ by repeating twice every coordinate. That is, strictly speaking, $A$ is permutation equivalent to $\{ (h, h) | h \in C_{\gamma, \delta} \}$. Indeed, given $v \in Z_2^d \times Z_4^d$ of order 4 and an affine function $f \in A$, the values $\varphi^+(f(v))$ and $\varphi^+(f(-v))$ of the corresponding codeword of $C_{\gamma, \delta}$ each occurs both in $\varphi(f(v))$ and $\varphi(f(-v))$. If the order of $v \in Z_2^d \times Z_4^d$ is 2 or less, then $\varphi^+(f(\cdot))$ is duplicated in $\varphi(f(\cdot))$.

Finally, it is easy to check that the minimum Lee distance for the set of affine functions $A$ is $n = 2^d + 2d$; so the minimum Hamming distance of $C_{\gamma, \delta}$ is the half of this value, $n/2$.

**Lemma 3:** Let $f : Z_2^d \times Z_4^d \to Z_4$ be an affine function. Then $h(\cdot) = \varphi^+(f(\cdot))$ belongs to $C_{\gamma, \delta}$.

**Proof:** In the case that $f(\overline{0}) \in \{0, 2\}$, $C_{\gamma, \delta}$ contains $h$ by definition. On the other hand, if $f(\overline{0}) = \{1, 3\}$, we will use that $\varphi^+(l) = \varphi^+(3-l)$ for $l \in Z_4$. Then, $h(\cdot) = \varphi^+(f(\cdot)) = \varphi^+(3-f(\cdot))$. Since $3-f(\cdot)$ is an affine function and $3-f(\overline{0}) \in \{0, 2\}$, we obtain that $h \in C_{\gamma, \delta}$.

**Theorem 1:** The $Z_2^d$-linear Hadamard code $B_{\gamma, \delta}$ of length $n$ and type $(0, n/2; \gamma, \delta)$ is permutation equivalent to the $Z_2^d \times Z_4^d$-linear code $C_{\gamma+1,d}$ of type $(\alpha, (n-\alpha)/2; \gamma+2, \delta-1)$ with $\alpha = n/2^{d-1}$.

**Proof:** Consider a function $f$ in $B$ and the related function $g(v, e) = f(v) + 2ef(\overline{0})$, where $v \in Z_2^d \times Z_4^d$ and $e \in Z_2$. We can see that

\[
\varphi(f(v)) = (\varphi^+(g(v, 1)), \varphi^+(g(v, 0))),
\]

\[
\varphi(f(-v)) = (\varphi^+(g(v, 1)), \varphi^+(g(-v, 0))).
\]

In order to check these equalities, it is convenient to represent $f(v)$ as $f_0(v) + f(\overline{0})$, where $f_0 : Z_2^d \times Z_4^d \to Z_2$ is a group homomorphism (in particular, $f_0(-v) = -f_0(v)$).

Since $g$ is an affine function from $v \in Z_2^d \times Z_4^d$ to $Z_4$, we can deduce from Lemma 3 that there is a fixed coordinate permutation that sends every codeword of $B_{\gamma, \delta}$ to a codeword of $C_{\gamma+1,d}$.

**Corollary 1:** There are exactly $\left(\frac{d}{2}\right)$ nonequivalent $Z_2 \times Z_4$-linear Hadamard codes of length $2^d$.

III. THE MONOMIAL AUTOMORPHISM GROUP OF THE $Z_2 \times Z_4$-ADDITIVE HADAMARD CODES, $\alpha = 0$

In this and next sections, we establish the structure and the order of the monomial automorphism group for the $Z_2 \times Z_4$-additive Hadamard codes. We start with the $Z_2 \times Z_4$-additive Hadamard codes with $\alpha = 0$.

Recall that the $Z_2 \times Z_4$-additive Hadamard code of type $(0, 2^{\gamma+2d}; \gamma, \delta + 1)$ can be considered as the set $B = B_{\gamma, \delta}$ of all affine functions from $Z_2^d \times Z_4^d$ to $Z_4$. As the elements of $Z_2^d \times Z_4^d$ play the role of coordinates, the coordinate permutations are the permutations of $Z_2^d \times Z_4^d$, and the action of such permutation $\sigma$ on a function $f$ on $Z_2^d \times Z_4^d$ can be expressed as $\sigma f(v) = f(\sigma^{-1}(v))$. The action of a sign change $\tau$ can be expressed as $\tau f(v) = f(v) r(v)$, where $r$ is the corresponding function from $Z_2^d \times Z_4^d$ to $\{1, 3\}$.

Assume we have an affine function $r$ from $Z_2^d \times Z_4^d$ to $\{1, 3\}$; note that $r(v) = r(-v)$ for all $v$. Let $\text{supp}(r)$ be the set of elements of $Z_2^d \times Z_4^d$ whose image by $r$ is 3. By $\tau_r$, we denote the transformation that changes the sign of the value of a function $f \in B_{\gamma, \delta}$ at the coordinates given by the elements of $\text{supp}(r)$: $\tau_r f(v) = f(v) r(v)$. By $\rho_r$, we denote the permutation of $Z_2^d \times Z_4^d$ that changes the sign of the elements of $\text{supp}(r)$: $\rho_r f(v) = f(r(v))$.

**Theorem 2:** The monomial automorphism group $\text{MAut}(B_{\gamma, \delta})$ of the $Z_2 \times Z_4$-additive Hadamard code $B_{\gamma, \delta}$ of type $(0, 2^{\gamma+2d}; \gamma, \delta + 1)$ consists of all transformations $\tau_r, \rho_r, \sigma$ where $\sigma$ is an affine permutation of $Z_2^d \times Z_4^d$ and $r$ is an affine function from $Z_2^d \times Z_4^d$ to $\{1, 3\}$ ($\tau_r$ and $\rho_r$ are the sign change and the permutation of $Z_2^d \times Z_4^d$ assigned to $r$ as above). The cardinality of this group satisfies

\[
|\text{MAut}(B_{\gamma, \delta})| = 2^{2\gamma+2\delta + 2d + 3} \prod_{i=1}^{\gamma} (2^i - 1) \prod_{j=1}^{\delta} (2^j - 1).
\]

**Proof:** The statement of the theorem is straightforward from the following three claims.

(i) Every transformation from the statement of the theorem belongs to $\text{MAut}(B)$. Obviously, $\sigma$ sends $B$ to $B$, as the composition of an affine permutation and an affine function is an affine function, too. It remains to check that $\tau_r, \rho_r \in \text{MAut}(B)$.

Consider an affine function $g(\cdot) = l(\cdot) + c(\cdot)$, where $l$ is a linear function and $c$ is a constant function, $c(\cdot) \equiv a$. Since $l(-v) = -l(v)$ and $r(v) = r(-v)$, we have $\tau_r \rho_r(l(\cdot)) = l$. Further, $\rho_r c(\cdot) = c(\cdot)$ and $\tau_r c(\cdot) = a r(\cdot)$. Therefore, we see that $\tau_r, \rho_r$ is an affine function and claim (i) is proved.

(ii) If $f \in \text{MAut}(B)$, where $\psi$ is a permutation of $Z_2^d \times Z_4^d$ and $r$ is a sign change, then $r = \tau_r$ for some affine function $r$. Indeed, consider the constant function $g(\cdot) = 1$, which obviously belongs to $B$. Then $\psi(g(\cdot)) = g$. Denote $r(\cdot) = \tau g(\cdot)$. Since $\tau g(\cdot) = \tau(\psi(g(\cdot)))$ is affine, we find that $r$ is also affine. It is straightforward that $r = \tau_r$. 

functions. Finally, \( \sigma \in \text{MAut}(B) \) is affine. Let \( \sigma_1', \ldots, \sigma_\gamma' : Z_2^4 \times Z_4^4 \to Z_2 \) and \( \sigma_\delta', \ldots, \sigma_\delta'' : Z_2^4 \times Z_4^4 \to Z_4 \) be the components of the vector-function \( \sigma^{-1} \).

That is,

\[
\sigma^{-1}(v) = (\sigma_1'(v), \ldots, \sigma_\gamma'(v), \sigma_\delta'(v), \ldots, \sigma_\delta''(v)).
\]

Now, consider the function \( f_i : Z_2^4 \times Z_4^4 \to Z_4 \) defined as \( f_i(x_1, \ldots, x_\gamma, y_1, \ldots, y_\delta) = 2x_i, \ i \in \{1, \ldots, \gamma \} \). This function is affine and, as \( \sigma \in \text{MAut}(B) \), the function \( \sigma f_i \) is also affine. We have \( \sigma f_i(v) = f_i(\sigma^{-1}(v)) = 2\sigma_i'(v) \), which means that \( \sigma_i'(v) \) is an affine \( Z_4 \)-valued function. Similarly, considering \( g_j(x_1, \ldots, x_\gamma, y_1, \ldots, y_\delta) = y_j, \ j \in \{1, \ldots, \delta \} \), we see that \( \sigma_j'(v) \) is affine, \( j \in \{1, \ldots, \delta \} \). Since all the components are affine, we conclude that \( \sigma^{-1} \) and \( \sigma \) are affine.

Now, assume we have a transformation \( \xi = \tau \psi \) from \( \text{MAut}(B) \), where \( \psi \) is a permutation of \( Z_2^4 \times Z_4^4 \) and \( \tau \) is a sign change. By claim (ii), we have \( \tau = \tau_r \) for some affine \( (1,3) \)-valued function \( r \). By claim (i), the permutation \( \sigma = \rho^{-1}_r \psi = \rho^{-1}_r \tau^{-1} \xi \) belongs to \( \text{MAut}(B) \), and by claim (iii) it is affine. Then, \( \xi = \tau_r \rho_r \sigma \).

Let us calculate the cardinality of the group. An affine permutation is uniquely represented as the composition of a linear permutation and a translation. There are \( T = |Z_2^4 \times Z_4^4| = 2^{2+3\gamma} \) different translations. To choose a linear permutation of \( Z_2^4 \times Z_4^4 \), one should choose the images \( y_1, \ldots, y_\delta, x_1, \ldots, x_\gamma \) of the elements \((0,0), (010,0), \ldots, (001), \) respectively, i.e., \( \delta \) elements of order 2 and \( \gamma \) elements of order 4, spanning \( Z_2^4 \times Z_4^4 \). The first element \( y_1 \) can be chosen in \( 2^{2+4\delta} - 2^{2\delta} \) ways. To choose \( y_j \), one can choose an element of order 4 in the factor-group \( Z_2^4 \times Z_4^4/(y_1, \ldots, y_j-1) \) (in \( 2^{2+4\delta-j+1+2^{2\delta-j+1}} \) ways) and a representative in the chosen coset of \( (y_1, \ldots, y_j-1) \) (in \( 4^{2\gamma-1} \) ways). Totally, there are

\[
Y = \prod_{j=1}^{\delta} (4^{2\gamma} - 2^{2\delta+2\gamma-1})
= 2^{2^\gamma+3\gamma} \prod_{j=1}^{\delta} (2^j - 1)
\]

to choose \( y_1, \ldots, y_\delta \). After choosing \( y_1, \ldots, y_\delta, x_1, \ldots, x_{i-1}, \) the element \( x_i \) can be chosen arbitrarily from the elements of order 2 of \( Z_2^4 \times Z_4^4 \setminus (y_1, \ldots, y_\delta, x_1, \ldots, x_{i-1}) \), in \( 2^{2\gamma+2\delta-1} \) ways. Totally, there are

\[
X = \prod_{i=1}^{\gamma} (2^{2\gamma} - 2^{2\delta-1})
= 2^{2^\gamma+\frac{3\gamma}{2}} \prod_{i=1}^{\gamma} (2^i - 1)
\]

to choose \( x_1, \ldots, x_\gamma \) after \( y_1, \ldots, y_\delta \). An affine function \( r \) is the sum of the coordinates with coefficients from \( \{0,2\} \) and a constant from \( \{1,3\} \); so there are \( F = 2^{2+3\gamma+1} \) such functions. Finally, \( |\text{MAut}(B)| = TYXF \).

IV. THE MONOMIAL AUTOMORPHISM GROUP OF THE \( Z_2^2 Z_4^4 \)-ADDITIVE HADAMARD CODES, \( \alpha \neq 0 \)

Recall that the \( Z_2^2 Z_4^4 \)-linear Hadamard code \( \mathcal{C}_{\gamma,\delta} \) of type \((2^{\gamma+\delta}; \beta; \gamma + 1, \delta)\) can be considered as the set of functions \( \varphi^+(f(v)) \) where \( f \) belongs to the set \( \mathcal{A} \) of affine functions from \( Z_2^2 \times Z_4^4 \) to \( Z_4 \) that map the all-zero vector to 0 or 2. Equivalently,

\[
\mathcal{A} = \{ f : Z_2^2 \times Z_4^4 \to Z_4 \mid f \text{ is affine and } f(-x) = -f(x) \ \forall x \}. \tag{1}
\]

A pair of opposite elements of \( Z_2^2 \times Z_4^4 \) is considered as a pair of coordinates of the code \( \mathcal{C}_{\gamma,\delta} \), corresponding to \( 0 \) and \( 2 \) \( Z_4 \)-coordinates of the \( \mathcal{C}_{\gamma,\delta} \). Hence, every monomial automorphism \( \mathcal{C}_{\gamma,\delta} \) corresponds to a permutation \( \sigma \) of \( \mathcal{C}_{\gamma,\delta} \) that preserves the negation, i.e., \( \sigma(-x) = -\sigma(x) \). Denote the set of all such automorphisms by \( \text{Aut}^{-}(\mathcal{C}_{\gamma,\delta}) \); so, \( \text{Aut}^{-}(\mathcal{C}_{\gamma,\delta}) \subseteq \text{MAut}(\mathcal{C}_{\gamma,\delta}) \).

We start from considering the automorphisms of \( \mathcal{C} \).

**Lemma 4:** \( \text{PAut}(\mathcal{A}) \) is the set of all affine permutations of \( Z_2^2 \times Z_4^4 \) that preserve the negation.

**Proof:** By (1), any affine permutation \( \sigma \) of \( Z_2^2 \times Z_4^4 \) that satisfies \( \sigma(-x) = -\sigma(x) \) is an automorphism of \( \mathcal{A} \). Following the arguments of claim (iii) in the proof of Theorem 2 we can see that any component of \( \sigma \) from \( \text{PAut}(\mathcal{A}) \) is affine and, moreover, preserves the negation. Hence, it is true for the whole \( \sigma \).

**Lemma 5:** \( \text{Aut}^{-}(\mathcal{C}_{\gamma,\delta}) \subseteq \text{PAut}(\mathcal{A}) \).

**Proof:** It is straightforward from the definition of \( \mathcal{C}_{\gamma,\delta} \) that \( \text{PAut}(\mathcal{A}) \subseteq \text{Aut}(\mathcal{C}_{\gamma,\delta}) \). Since by Lemma 4 the permutations from \( \text{PAut}(\mathcal{A}) \) preserve the negation, we have \( \text{PAut}(\mathcal{A}) \subseteq \text{Aut}^{-}(\mathcal{C}_{\gamma,\delta}) \).

Given a \( Z_4 \)-valued function \( x \) from \( \mathcal{C}_{\gamma,\delta} \), we can reconstruct the corresponding \( Z_4 \)-valued function \( f_x \) from \( \mathcal{A} \) by the rule \( f_x(v) = \varphi^{-1}(x(v), x(-v)) \). Since an automorphism \( \sigma \) from \( \text{Aut}^{-}(\mathcal{C}_{\gamma,\delta}) \) preserves the negation, we have

\[
\begin{align*}
\sigma f_x(v) &= f_x(\sigma^{-1}(v)) = \varphi^{-1}(x(\sigma^{-1})(v), x(-\sigma^{-1}(v))) \\
&= \varphi^{-1}(x(\sigma^{-1}(v)), x(-\sigma^{-1}(v))) \\
&= \varphi^{-1}(x(v), x(-v)) = f_x(v).
\end{align*}
\]

Consequently, such \( \sigma \) sends functions from \( \mathcal{A} \) to functions from \( \mathcal{A} \), which means \( \text{Aut}^{-}(\mathcal{C}_{\gamma,\delta}) \subseteq \text{PAut}(\mathcal{A}) \). The above lemmas and direct calculations, similar to that in Section III give the following result.

**Theorem 3:** The monomial automorphism group \( \text{MAut}(\mathcal{C}_{\gamma,\delta}) \) of the \( Z_2^2 Z_4^4 \)-additive Hadamard code \( \mathcal{C}_{\gamma,\delta} \) of type \((2^{\gamma+\delta}; \beta; \gamma + 1, \delta)\) is isomorphic to the group of affine permutations of \( Z_2^2 \times Z_4^4 \) that preserve the negation. The cardinality of this group satisfies

\[
|\text{MAut}(\mathcal{C}_{\gamma,\delta})| = 2^{2\gamma+2^\gamma+2^\delta+2^{\gamma+2^\delta}} \prod_{i=1}^{\gamma} (2^i - 1) \prod_{j=1}^{\delta} (2^j - 1).
\]
V. AN UPPER BOUND ON THE ORDER OF THE PERMUTATION AUTOMORPHISM GROUP

In this and next sections, we establish the structure and the order of the permutation automorphism group for the $Z_2Z_4$-linear Hadamard codes. In the rest of the paper, we consider $Z_2Z_4$-linear codes, which are binary codes, and in the examples, we will use 0, 1, 2, and 3 as short notations for 00, 01, 11, and 10, respectively, placed in the coordinates $\alpha + 2i - 1, \alpha + 2i, i \in \{1, \ldots, \beta\}$.

Let $C = C_{\gamma, \delta}$ be a $Z_2Z_4$-linear Hadamard code of length $n$ and type $(\alpha, \beta; \gamma + 1, \delta)$ with $\alpha \neq 0$, where $n = 2^{\gamma+2\delta}$. The code $C$ is generated by $\gamma = \gamma + 1$ words $y$, $u_1, \ldots, u_\delta$, order 2 and $\delta$ words $v_1, \ldots, v_\delta$ of order 4, where $y$ is the all-one word of length $n$. Let $G = G_{\gamma, \delta}$ be the matrix formed by the rows $y, u_1, \ldots, u_\delta, v_1, \ldots, v_\delta$. Let $G$ be the matrix where the columns are all $2^{\gamma+\delta}$ binary columns from $\{0,1\}^\delta$ and half of $2^\gamma 2^{2\delta} - 2^{\gamma+\delta}$ quaternary columns of order 4 from $\{0,1,2,3\}^\delta \times \{0,2\}^\gamma$, each pair of opposite column vectors being represented by only one column, see e.g. [23]. Then, $G$ can be seen as the matrix $G$ where the quaternary columns are written as pairs of binary columns under the Gray map. We assume that $\delta \geq 2$, since for $\delta = 0$ and $\delta = 1$, $C$ is the binary linear Hadamard code of length $n = 2^\gamma$, so its permutation automorphism group $GA(t, 2)$, which has order $2^t(2^t - 1)(2^t - 2) \ldots (2^t - 2^t)$ [19].

The kernel of the code $C$, $\text{Ker}(C)$, is generated by the $1 + \delta + \gamma$ words $y, w_1, \ldots, w_\delta, u_1, \ldots, u_\delta$, where $w_j = v_j \ast v_j$, of order 2 [23]. Let $K = K_{\gamma, \delta}$ be the matrix formed by these rows $y, w_1, \ldots, w_\delta, u_1, \ldots, u_\delta$. We assume w.l.o.g. that the columns of $K$ are ordered lexicographically.

**Lemma 6 [23]:** The matrix $K$ is a generator matrix for $\text{Ker}(C)$. In particular, $\text{Ker}(C)$ consists of all the elements of the group $(C, \ast)$ of order 2 or less (without 1s and 3s).

**Example 1:** Let $C_{1,2}$ be the $Z_2Z_4$-linear Hadamard length $n = 32$ and type $(8, 12; 2, 2)$, that is, generated by $\gamma = \gamma + 1 = 2$ words of order 2 and $\delta = 2$ words of order 4. Then,

$$G_{1,2} = \begin{pmatrix} 1111 & 1111 & 22 & 22 & 22 & 22 & 22 & 22 \\ 0011 & 0011 & 02 & 02 & 11 & 11 & 11 & 11 \\ 0101 & 0101 & 11 & 11 & 02 & 02 & 13 & 13 \\ 0000 & 1111 & 00 & 22 & 00 & 22 & 00 & 22 \end{pmatrix}$$

and

$$K_{1,2} = \begin{pmatrix} 1111 & 1111 & 22 & 22 & 22 & 22 & 22 & 22 \\ 0000 & 0000 & 00 & 00 & 22 & 22 & 22 & 22 \\ 0000 & 0000 & 22 & 22 & 00 & 00 & 22 & 22 \\ 0000 & 1111 & 00 & 22 & 00 & 22 & 00 & 22 \end{pmatrix}$$

**Example 2:** Let $C_{0,3}$ be the $Z_2Z_4$-linear Hadamard code of length $n = 64$ and type $(8, 28; 1, 3)$, that is, generated by $\gamma = \gamma + 1 = 1$ word of order 2 and $\delta = 3$ words of order 4. Then, $G_{0,3}$ and $K_{0,3}$ are, respectively,

$$G_{0,3} = \begin{pmatrix} 11111111 & 2222 & 2222 & 2222 & 2222 & 2222 & 2222 \\ 00001111 & 0222 & 0222 & 0222 & 0222 & 0222 & 0222 \\ 00110011 & 0202 & 1111 & 0222 & 0222 & 1133 & 1133 \\ 01010101 & 1111 & 0202 & 1313 & 0202 & 1313 & 0202 \end{pmatrix}$$

$$K_{0,3} = \begin{pmatrix} 11111111 & 2222 & 2222 & 2222 & 2222 & 2222 & 2222 \\ 00001111 & 0222 & 0222 & 0222 & 0222 & 0222 & 0222 \\ 00110011 & 0202 & 1111 & 0222 & 0222 & 1133 & 1133 \\ 01010101 & 1111 & 0202 & 1313 & 0202 & 1313 & 0202 \end{pmatrix}$$

All coordinates are naturally divided into $2^{\gamma+\delta}$ groups of size $2^\delta$, which will be referred to as blocks, such that the columns of $K$ in a block coincide. Similarly, by the values in the rows of $K$ given by $w_1, \ldots, w_\delta$, the coordinates are divided into $2^\delta$ groups of size $\alpha = 2^{\gamma+\delta}$, which will be referred to as macroblocks.

As representatives of the kernel cosets that partition the code $C$, we can choose the combinations $v(s) = s_1v_1 \ast \ldots \ast s_3v_3$, where $s = (s_1, \ldots, s_3) \in \{0,1\}^3$, that is, $C = \bigcup_{s \in \{0,1\}^3} (\text{Ker}(C) + v(s))$. Let $S = S_{\gamma, \delta}$ be the matrix consisting from the vectors $v(s)$, $s \in \{0,1\}^3$, as rows.

**Lemma 7:** For any $s_1, \ldots, s_3 \in \{0,1\}$, we have

$$v(s) = s_1v_1 \ast \ldots \ast s_3v_3 = \sum_{j=1}^{s_j} v_j + \sum_{1 \leq j < \delta} s_j s_j \ast w_j \ast w_j$$

where $\ast$ is the component-wise product of two vectors.

**Proof:** Straightforward using that $v_i \ast v_j = v_i + v_j + w_i \ast w_j$.

**Example 3:** Considering the $Z_2Z_4$-linear Hadamard code $C_{1,2}$ from Example [1] $S_{1,2}$ is

$$S_{1,2} = \begin{pmatrix} v(00) & 00 & 00 & 00 \end{pmatrix} = \begin{pmatrix} 0000 & 0000 & 0000 & 0000 \end{pmatrix}$$

$$v(01) = 01010101 \begin{pmatrix} 0000 & 0000 & 0000 & 0000 \end{pmatrix}$$

$$v(11) = 01101101 \begin{pmatrix} 0000 & 0000 & 0000 & 0000 \end{pmatrix}$$

Similarly, considering the $Z_2Z_4$-linear Hadamard code $C_{0,3}$ from Example [2]

$$S_{0,3} = \begin{pmatrix} v(00) & 00 & 00 & 00 & 00 \end{pmatrix} = \begin{pmatrix} 0000000000000000 \end{pmatrix}$$

$$v(01) = 01010101 \begin{pmatrix} 0000000000000000 \end{pmatrix}$$

$$v(11) = 01101101 \begin{pmatrix} 0000000000000000 \end{pmatrix}$$
Lemma 8: Any automorphism of $C$ stabilizes the partitions of the coordinates into blocks and macroblocks.

Proof: Since any automorphism of the code $C$ is an automorphism of its kernel $\text{Ker}(C)$ [22], the image of any block is obviously a block.

In order to find an invariant for the macroblocks, we use the structure of the linear span of $C$. As was shown in [23], the linear span is generated by the words

\[
\begin{align*}
y_j &= v_j \ast v_j, \quad j \in \{1, \ldots, \delta\}; \\
w_j \cdot w_j', & \quad 1 \leq j < j' \leq \delta; \\
u_i, & \quad i \in \{1, \ldots, \gamma\}; \\
v_j, & \quad j \in \{1, \ldots, \delta\}.
\end{align*}
\]

(3)

It is straightforward to see the following fact:

(i) The matrix formed from $u_1, \ldots, u_\delta, v_1, \ldots, v_\delta, u_1, \ldots, u_\gamma$ as rows consists of all different binary columns of height $\gamma + 2\delta$.

Then, we observe the next two facts:

(ii) Every word of the linear span whose weight is different from $n/2$ has the same value in the coordinates of a fixed macroblock. Indeed, if a linear combination $x$ of the basis words [3] has different values in the same macroblock, then either some $u_i$ or some $v_j$ is involved to generate $x$. Assume $z$, which is $u_i$ or $v_j$, is involved. As follows from claim (i), for every coordinate, there is another one such that the values of $z$ are different in these two coordinates, while the values of any other basis word from (3) coincide. Hence, $x$ has different values in each such pair of coordinates, which means that its weight is $n/2$.

(iii) For every two different macroblocks $I$ and $I'$, the linear span contains a word of weight $n/4$ that has different values in the coordinates from these two macroblocks. Indeed, by the definition of the macroblocks, there is $w_j$ that has different values in the coordinates of $I$ and $I'$. Then, for any other $w_{j'}$ (recall that $\delta \geq 2$), we have $w_j = w_j \cdot w_{j'} + w_j \cdot (w_{j'} + y)$. Hence, at least one of two words $w_j \cdot w_{j'}$ and $w_j \cdot (w_{j'} + y)$ of weight $n/4$ differs in the coordinates of $I$ and $I'$.

As follows from claims (ii) and (iii), there is an invariant that indicates whether two coordinates belong to the same macroblock or not: coordinates $k$ and $k'$ are in different macroblocks if and only if the linear span of $C$ contains a word $x = (x_1, \ldots, x_\delta)$ of weight less than $n/2$ such that $x_k \neq x_{k'}$. As an automorphism of a code is obviously an automorphism of its linear span, the partition of the coordinates into macroblocks is stabilized.

Lemma 9: Let $\psi$ be an automorphism of $C$. Then

(i) For every $j$ from 1 to $\delta$, $\psi(w_j)$ is a linear combination of $y, w_1, \ldots, w_\delta$.

(ii) For every $i$ from 1 to $\gamma$, $\psi(u_i)$ is a linear combination of $y, w_1, \ldots, w_\delta, u_1, \ldots, u_\gamma$.

(iii) For every $s \in \{0, 1\}^\delta$,

\[
\psi(v(s)) = v(\sigma(s)) + ay + \sum_{j=1}^{\delta} c_j w_j + \sum_{i=1}^{\gamma} b_i u_i,
\]

where $\sigma$ is a permutation of the set $\{0, 1\}^\delta$, $a = a(s) \in \{0, 1\}$, $c_j = c_j(s) \in \{0, 1\}$, $b_i = b_i(s) \in \{0, 1\}$.

(iv) The permutation $\sigma$ is linear.

(v) If $\psi(u_i) = u_i$ and $\psi(w_j) = w_j$ for all $i \in \{1, \ldots, \gamma\}$ and $j \in \{1, \ldots, \delta\}$, then the functions $a = a(s), c_j = c_j(s), b_i = b_i(s)$ are linear.

Proof: Since $\psi$ is an automorphism of $\text{Ker}(C)$ [22], the permuted matrix $\psi(K)$ remains a generator matrix for $\text{Ker}(C)$. So, (ii) is obvious. Taking into account Lemma 8 we see that (i) holds as well.

(iii) For every $s \in \{0, 1\}^\delta$, since $\psi(v(s))$ belongs to $C = \bigcup_{s \in \{0, 1\}^\delta} (\text{Ker}(C) + v(s))$, it can be represented as $v(\sigma(s)) + ay + \sum_{j=1}^{\delta} c_j w_j + \sum_{i=1}^{\gamma} b_i u_i \in v(\sigma(s)) + \text{Ker}(C)$ for some $\sigma(s) \in \{0, 1\}^\delta, a, c_1, \ldots, c_\delta, b_1, \ldots, b_\gamma \in \{0, 1\}$. As $\psi$ is a bijective mapping and $\psi$ is an automorphism of $\text{Ker}(C)$, the mapping $\sigma : \{0, 1\}^\delta \to \{0, 1\}^\delta$ is bijective too.

(iv) By Lemmas 7 and 6 we have that $v(s) + v(s') + v(s'') \in \text{Ker}(C)$ if and only if $s + s' + s'' = 0$. From (4), we see that $\psi(v(s)) + \psi(v(s')) + \psi(v(s'')) \in \text{Ker}(C)$ if and only if $\sigma(s) + \sigma(s') + \sigma(s'') = 0$. The condition $v(s) + v(s') + v(s'') \in \text{Ker}(C)$ is readily the same as $\psi(v(s)) + \psi(v(s')) + \psi(v(s'')) \in \text{Ker}(C)$ since $\psi \in \text{Aut}(\text{Ker}(C))$. Thus, $s + s' + s'' = 0$ is equivalent to $\sigma(s) + \sigma(s') + \sigma(s'') = 0$, which means that $\sigma$ is linear.

(v) The hypothesis of statement (v) implies that $\psi$ does not permute the blocks. By Lemma 7 for every block $I$ such that all but one $w_1, \ldots, w_\delta$ vanish on $I$, the mapping $s \mapsto v(s)|_I$ is linear. Moreover, permuting the coordinates within the block does not change this property, i.e., the mapping $s \mapsto \psi(v(s))|_I$ is linear too. We first consider the first such block $I = \{1, \ldots, 2^\delta\}$. Since $w_1, \ldots, w_\delta$ and $u_1, \ldots, u_\gamma$ vanish on $I$, equation (4) turns to $\psi(v(s))|_I = v(\sigma(s))|_I + a(s)y|_I$. We see that the mapping $s \mapsto a(s)$ must be linear. Similarly, considering the block $I$ such that all $w_1, \ldots, w_\delta$ and $u_1, \ldots, u_\gamma$ except $u_i$ (or $w_j$) vanish on $I$, we obtain the linearity of the mapping $s \mapsto b_i(s)$ for $i = 1, \ldots, \gamma$ (or $j = 1, \ldots, \delta$, respectively).

Lemma 10: Let $\psi$ be an automorphism of $C$ such that $\psi(u_i) = u_i$ and $\psi(w_j) = w_j$ for all $i \in \{1, \ldots, \gamma\}$ and $j \in \{1, \ldots, \delta\}$. If $\delta \geq 3$, then $\sigma$ defined in Lemma 9 is the identity permutation.

Proof: The hypothesis of the lemma implies that $\psi$ stabilizes every block of coordinates. The idea of the proof is to show that any nonidentical permutation $\sigma$ breaks the linear relations between the vectors $v(s)$ in a fixed block $I$ of coordinates.

We already know that $\sigma : \{0, 1\}^\delta \to \{0, 1\}^\delta$ is a nonsingular linear transformation. It remains to show that $\sigma$ fixes every basis vector $e_j$ that has 1 in the $j$th position and 0 otherwise. We will prove this for $e_1$, as the other cases are similar. First, let us prove for example that $\sigma(e_1) \neq t$ for every $t = (t_1, \ldots, t_\delta)$ such that $t_2 = 1$. Consider a block $I$ such that all $w_1, \ldots, w_\delta$ vanish on $I$ except vectors $w_2$ and $w_3$, for which $w_2|_I = w_3|_I = \bar{T}$ (where $\bar{T}$ is the all-one word of length $2^\delta$). Note that $w_3$ exists because $\delta \geq 3$. Then,
by Lemma 7
\[ v(s)|_I = \sum_{j=1}^{\delta} s_j v_j|_I + s_2 s_3 T, \quad s = (s_1, \ldots, s_3) \in \{0, 1\}^3. \]

It is straightforward to see that the mapping \( v^I(s) = v(s)|_I : \{0, 1\}^3 \to \{0, 1\}^2 \) is linear in the direction \( e_1 \), since \( v^I(s) + v^I(s + e_1) = v_I|_I \) is constant; and it is nonlinear in the direction \( t \), as \( v^I(s) + v^I(s + t) = x + (s_2 s_3 + s_3) T \) is not constant, where \( x \) is a constant vector. However, we see from \[ \text{(4)} \]
that \( v^I(\sigma(s)) \) is also linear in the direction \( e_1 \), that is, \( v^I(s) \) is linear in the direction \( \sigma(e_1) \). We see that \( \sigma(e_1) \neq t \).

Similarly, this holds for every \( t \) such that \( t_k = 1 \) for some \( k \neq 1 \); so, the only remaining possibility is \( \sigma(e_1) = e_1 \). Similarly, \( \sigma(e_j) = e_j \) for every \( j \); hence the linear map \( \sigma \) is just the identity.

**Example 4:** In the matrix \( S_{0,3} \) of Example 3 we can see that \( v^I(s) + v^I(s + t) = v_I|_I \), so it does not depend on \( s \) for the forth block \( I = \{25, \ldots, 32\} \) and for \( t = (1, 0, 0) \). This is not true for \( t = (0, 0, 1) \).

**Proposition 1:** If \( \delta \geq 2 \), then the order of the automorphism group of \( C \) satisfies
\[ |\text{Aut}(C)| \leq p \cdot 2^{n_2 (\gamma + 1) + 2 \delta + \frac{2}{\delta (\delta + 1)} \sum_{i=1}^{\gamma} (2^i - 1) \prod_{j=1}^{\delta} (2^j - 1)}, \]
where \( p = 6 \) if \( \delta = 2 \) and \( p = 1 \) if \( \delta \geq 3 \).

**Proof:** Let \( \psi \in \text{Aut}(C) \). We evaluate the number of possibilities for the matrices \( \psi(K) \) and \( \psi(S) \). Clearly, \( \psi(y) = y \).

By Lemma 9 for every \( j \) from 1 to \( \delta \), \( \psi(w_j) \) is a linear combination of \( y, w_1, \ldots, w_{\delta} \). However, as \( \psi(w_j) \) must be linearly independent on \( y, \psi(w_1), \ldots, \psi(w_{\delta - 1}) \), there are at most \( 2^{\delta + 1} - 2^\delta \) possibilities for \( \psi(w_j) \), for each choice of \( y, \psi(w_1), \ldots, \psi(w_{\delta - 1}) \). Similarly, for every \( i \) from 1 to \( \gamma \), there are at most \( 2^{\delta + \gamma + 1} - 2^{\delta + i} \) possibilities for \( \psi(u_i) \). In total, \( \psi(K) \) is one of the
\[ \delta \prod_{j=1}^{\delta} \left( 2^{\delta + 1} - 2^j \right) \prod_{i=1}^{\gamma} \left( 2^{\delta + \gamma + 1} - 2^{\delta + i} \right), \]
\[ = 2^{\gamma (\gamma + 1) + \gamma \delta + \frac{2}{\delta (\delta + 1)} \sum_{i=1}^{\gamma} (2^i - 1) \prod_{j=1}^{\delta} (2^j - 1)}, \]
matrices obtained from \( K \) by nonsingular transformations as above.

Now suppose that we know \( \psi(K) \) and count the possibilities for \( \psi(S) \). W.l.o.g., \( \psi(K) = K \). First, consider the case \( \delta \geq 3 \).

By Lemmas 9(iii), 9(v) and 10 all \( \psi(v(s)) \) are uniquely defined by \( 1 + \delta + \gamma \) linear functions \( a, c_1, \ldots, c_\delta, b_1, \ldots, b_{\gamma} : \{0, 1\}^\delta \to \{0, 1\} \). Note that, in the current corollary, we do not state yet that every possibility is realizable by some \( \psi \). We totally have at most \( (2^{\delta + 1} + \gamma + \delta) \) choices for \( \psi(S) \), given \( \psi(K) \).

Multiplying this last value by \( \delta \), we obtain the required bound. Finally, if \( \delta = 2 \), then the same arguments work with the only exception that there are additional possibilities to choose a nonsingular linear mapping \( \sigma : \{0, 1\}^2 \to \{0, 1\}^2 \), accordingly to Lemma 9(iii) and 9(iv), which gives the factor \( p = 6 = (2^2 - 1)(2^2 - 2) \).

**VI.** **The permutation automorphism group of a**

**Z₂Z₄-linear Hadamard code**

By Lemma 3 any nonsingular affine transformation of \( Z^2_2 \times Z^4_2 \) belongs to \( \text{Aut}(C) \). Therefore, since for \( \delta \geq 3 \), the number of nonsingular affine transformations coincides with the upper bound given in Proposition 1, we obtain the following result:

**Theorem 4:** The permutation automorphism group of the \( Z^2_2 \times Z^4_2 \)-linear Hadamard code \( C \) of type \( (\alpha, \beta; \gamma + 1, \delta) \), with \( \delta \geq 3 \), is the group of nonsingular affine transformations of \( Z^4_2 \times Z^4_2 \). Therefore, its order is
\[ |\text{Aut}(C)| = 2^{\gamma (\gamma + 1) + 2 \delta + \frac{2}{\delta (\delta + 1)} \sum_{i=1}^{\gamma} (2^i - 1) \prod_{j=1}^{\delta} (2^j - 1)}. \]

It remains to consider the case \( \delta = 2 \).

**Lemma 11:** Let \( C \) be the \( Z^2_2 \times Z^4_2 \)-linear Hadamard code of type \( (\alpha, \beta; \gamma + 1, 2) \).

(i) Any nonsingular linear mapping \( \sigma : \{0, 1\}^2 \to \{0, 1\}^2 \), as defined in Lemma 3(iii), corresponds to an automorphism \( \psi \) of \( C \) that stabilizes every block.

(ii) Moreover, if this automorphism \( \psi \) is not identical, then it is not an affine transformation of \( Z^2_2 \times Z^4_2 \).

**Proof:** (i) There are exactly \( p = 6 = (2^2 - 1)(2^2 - 2) \) such permutations. For \( \gamma = 0 \), it is easy to check that the result is true. The coordinate permutations \( \psi \) corresponding to two permutations \( \sigma \) are shown on the following diagram:

The other three nonidentity variants for \( \sigma \) can be expressed from these two using composition.

\[ S_{0,2} = \begin{pmatrix} 0000 & 0000 & 0000 & 0000 \\
0111 & 0111 & 0101 & 0101 \\
0101 & 0101 & 0111 & 0111 \\
0110 & 0110 & 0110 & 1100 \end{pmatrix} \]

For \( \gamma \geq 1 \), the 4 rows \( v(s) \) of \( S_{\gamma,2} \), \( s \in \{0, 1\}^2 \), contain in each one of their 4 macroblocks of size \( 2^{\gamma + 2} \), the same coordinates corresponding to the same macroblock in the row \( v(s) \) of \( S_{0,2} \) repeated \( 2^\gamma \) times. Therefore, the result follows.

(ii) We first note that, as follows from the first part of the proof, the considered automorphisms fix a coordinate from every block. Now, let us consider an arbitrary affine permutation \( \psi \) that fixes a coordinate from every block and show that it is the identity permutation \( \text{id} \). Assume, seeking a contradiction, that \( \psi \neq \text{id} \). Consider the map \( \xi = \psi - \text{id} \). It is an affine map from \( Z^2_2 \times Z^4_2 \) to \( Z^2_2 \times Z^4_2 \). It possesses the zero value in a point from every block and a nonzero value in at least one point. Consider a nonconstant linear mapping \( \lambda \) from the image of \( \xi \) onto \( \{0, 2\} \). Then the map \( \lambda \xi \) from \( Z^2_2 \times Z^4_2 \) to \( \{0, 2\} \) is affine and is not constantly zero. By Lemma 6 \( \xi \lambda \) belongs to the kernel of \( C \). However, as \( \xi \lambda \) is zero in a point from every block, by the definition of the blocks, it is constantly zero. We get a contradiction.

\[ \blacksquare \]
Theorem 5: The automorphism group of the $Z_2Z_4$-linear Hadamard code $C$ of type $(\alpha, \beta; \gamma + 1, 2)$ consists of all permutations expressed as $\psi\alpha$, where $\alpha$ is a nonsingular affine transformation of $Z_4 \times Z_2$ and $\psi$ is one of the six permutations defined in Lemma 7. The order of this automorphism group is 
\[ |\text{Aut}(C)| = 6 \cdot 2^\gamma(\gamma+1)^4 + 4^\gamma + 9 \cdot 3 \prod_{i=1}^{\gamma}(2^i - 1). \]

Proof: By Lemma 11(i), all the permutations are automorphisms of $C$. By Lemma 11(ii), they are mutually different. We can see that the lower bound given by counting all such permutations coincides with the upper bound from Proposition 1.
