Abstract

Farnesoid X receptor (FXR), the bile acid-activated nuclear receptor and member of the nuclear receptor superfamily, plays a key role in bile acid, lipid and glucose homeostasis. FXR is abundantly expressed in the kidney, but its physiological function remains mostly unknown. Recent studies have demonstrated that FXR is expressed in renal collecting ducts where it directly regulates the transcription of the aquaporin 2 (AQP2) gene. FXR gene deficiency results in a polyuric phenotype in mice. These results highlight a novel mechanism for FXR in mediating renal urine concentration independent of the antidiuretic hormone (ADH) system. FXR may represent a potential therapeutic target for treating diseases with urine concentrating defect, including hepatorenal syndrome and nephrogenic diabetes insipidus.

Keywords: Nuclear receptor; Water homeostasis; FXR; Aquaporin; Bile acid

Introduction

FXR belongs to the superfamily of nuclear receptor transcription factor and was originally named on the basis of its weak activation by farnesol. Shortly after that, it was termed bile acid receptor since bile acids at physiological levels were found to be potent endogenous ligands for this nuclear receptor [1]. As the bile acid nuclear receptor, FXR regulates hepatoenenteric circulation of bile acids through the bile acid transporter [2]. As a member of the metabolic nuclear receptors, it also regulates the expression of many target genes in lipid and glucose metabolism and participates in glucose and lipid homeostasis [3]. In the recent years, increasing evidence has demonstrated that FXR also takes part in biological processes of liver protection such as the liver detoxification and liver regeneration [4].

In addition to the liver and small intestine, FXR is highly expressed in the kidney. However, its physiological role remains mostly unknown. Activation of FXR has been shown to attenuate diabetic albuminuria and fibrosis [5]. Recently, it has been reported that FXR activation maintains endogenous gluthathione homeostasis and protects the kidney in uninephrectomized mice from obesity-induced injury [6]. These findings suggest that FXR may serve as a new therapeutic target to treat chronic kidney disease including diabetic nephropathy. However, to date the physiological role of FXR in the kidney remains poorly understood although FXR is highly expressed in the kidney. In this mini-review, we will discuss recent findings regarding the role of FXR in renal physiology with a focus on urine concentration regulation.

Intrarenal localization of FXR

As the first step to determine the biological significance of FXR in the kidney, a few groups have examined FXR's intrarenal localization using immunohistochemical staining technique [7,8]. It has been demonstrated that FXR is ubiquitously expressed in the epithelial cells of all renal tubules including the proximal tubules, distal convoluted tubules and collecting ducts. In contrast, FXR expression is very low in renal glomeruli [9,10]. These findings suggest that FXR may play an important role in water and solute reabsorption.

Effect of FXR activation and inactivation on urine concentration

High expression levels of FXR in renal tubules suggest a critical role this nuclear receptor might play in renal physiology. To determine the role of FXR in the kidney, we have treated mice with the endogenous FXR agonist, chenodeoxycholic acid (CDCA) and found that activation of FXR resulted in a significant decrease in urine output7. This finding indicates that FXR activation may increase urine concentration capacity. In support, in FXR gene knockout mice, a significant increase of urine volume was observed [7]. Collectively, these observations demonstrate that FXR may play a critical role in the maintenance of water homeostasis.

The role of FXR in renal AQP2 expression

Water reabsorption in the kidney is influenced by the water permeability and the osmotic gradient. Water permeability in renal tubules is determined by the expression and apical localization of many aquaporins (AQPs) [11]. Among them, AQP2 is selectively expressed in the principal cells of the collecting ducts, where it controls water reabsorption in this renal tubule segment and determines final urine volume. Although only a small amount of water is reabsorbed by renal collecting ducts, many regulatory mechanisms are involved in the regulation of AQP2 expression. The most important one is the AVP-V2 receptor system.

Arginin vasopressin (AVP or ADH) is synthesized by the hypothalamus and represents the most important hormone in
regulating water reabsorption in kidney. AVP interacts with the V2 receptor distributed at the basolateral membrane of collecting duct principal cells and enhances water reabsorption by increasing AQP2 expression and apical targeting through the cAMP-PKA signaling pathway [12-13]. We found that FXR activation increases, while FXR inactivation decreases, AQP2 expression and apical membrane localization in the collecting ducts. Therefore, FXR may help modulate urine volume via the regulation of AQP2 in the kidney.

**AQP2 is a direct target gene of FXR**

Both systemic and local mechanisms may be involved in the regulation of renal AQP2 expression. In mice treated with CDCA or deficient for FXR gene, no alteration of serum AVP concentrations and renal V2 receptor levels was observed, suggesting the change in urine volume may be the result of direct action of FXR in renal collecting ducts.

Previous studies on other nuclear receptors have demonstrated that AQP2 may be under the control of many nuclear receptors including glucocorticoid receptor (GR), aldosterone receptor (AR) or mineralocorticoid receptor (MR), liver X receptor beta (LXRXβ), estrogen receptor alpha (ER), and peroxisome proliferator activated receptor gamma (PPAR) in renal collecting duct cells [12-17], further supporting the possibility that FXR may directly regulate AQP2 expression in this tubular segment.

As a matter of fact, it has been reported that using both bioinformatics and ChIP-Seq approaches a functional FXR and RXRα heterodimer binding site was found in AQP4 gene, implying the direct gene regulation of FXR on AQP4 and possibly on other AQP channels. A few recent studies have showed that small heterodimer partner (SHP), another nuclear receptor, is an immediate target gene of FXR, which might be also involved in the effect of FXR on water homeostasis regulation [18-19].

Recently, our group has analyzed human and mouse AQP2 gene sequence and found a putative FXRE located in the promoter region of AQP2 gene. By using luciferase reporter and Chip assays, we further confirmed that activated FXR can bind to the FXRE site in the promoter of AQP2 gene, thereby significantly increasing AQP2 expression. Taken together, FXR is highly expressed in the kidney, especially in the renal collecting ducts, where its activation increases water reabsorption through directly upregulating AQP2 gene transcription.

**Perspective**

Renal collecting ducts are critical in determining urine volume under the control of both systemic hormone AVP and locally acting factors. Defects in the V2 receptor signaling pathway result in a polycystic phenotype, a state called nephrogenic diabetes insipidus (NDI) [9]. Currently, no effective treatment is available for patients with NDI. The finding that FXR activation reduces urine output via increasing AQP2 expression raises a possibility that clinically used CDCA may be a potential therapeutic agent for the treatment of this disease.

In addition, in patients with end-stage liver disease, advanced cirrhosis and cholestasis, renal function is frequently impaired with fluid retention due to increased renal water and sodium reabsorption, a clinical disorder known as hepatorenal syndrome [20].

In these patients, normal enterohepatic circulation of bile acids is disrupted, resulting in a high level of plasma bile acid. The findings that FXR activation increases AQP2 expression, while FXR inactivation decreases renal AQP2 abundance, support the idea that collecting duct FXR activation by increased exposure to both filtered and circulating bile acids may be involved in reduced water excretion in patients with hepatorenal syndrome. It also implies that FXR may represent a potential target for developing novel drugs in the treatment of this severe disorder with a very poor prognosis.
