Abstract. We propose a new approach to study the relation between the module categories of a tilted algebra $C$ and the corresponding cluster-tilted algebra $B = C \ltimes E$. This new approach consists of using the induction functor $- \otimes_C B$ as well as the coinduction functor $D(B \otimes_C D-)$.

We give an explicit construction of injective resolutions of projective $B$-modules, and as a consequence, we obtain a new proof of the $I$-Gorenstein property for cluster-tilted algebras. We show that $DE$ is a partial tilting and a $\tau$-rigid $C$-module and that the induced module $DE \otimes_C B$ is a partial tilting and a $\tau$-rigid $B$-module. Furthermore, if $C = \text{End}_A T$ for a tilting module $T$ over a hereditary algebra $A$, we compare the induction and coinduction functors to the Buan-Marsh-Reiten functor $\text{Hom}_{C_A}(T, -)$ from the cluster-category of $A$ to the module category of $B$. We also study the question which $B$-modules are actually induced or coinduced from a module over a tilted algebra.

1. Introduction

Cluster-tilted algebras are finite dimensional associative algebras which were introduced in [BMR] and, independently, in [CCS] for the type $A$.

One motivation for introducing these algebras came from Fomin and Zelevinsky’s cluster algebras [FZ]. To every cluster in an acyclic cluster algebra one can associate a cluster-tilted algebra, and the indecomposable rigid modules over the cluster-tilted algebra correspond bijectively to the cluster variables outside the chosen cluster. Generalizations of cluster-tilted algebras, the Jacobian algebras of quivers with potentials, were introduced in [DWZ], extending this correspondence to the non-acyclic types. Many people have studied cluster-tilted algebras in this context, see for example [BBT, BMR, BMR2, BMR3, CCS2, CC, CK, KR].

The second motivation came from classical tilting theory. Tilted algebras are the endomorphism algebras of tilting modules over hereditary algebras, whereas cluster-tilted algebras are the endomorphism algebras of cluster-tilting objects over cluster categories of hereditary algebras. This similarity in the two definitions lead to the following precise relation between tilted and cluster-tilted algebras, which was established in [ABS].

There is a surjective map

$$\{\text{tilted algebras}\} \twoheadrightarrow \{\text{cluster-tilted algebras}\}, \quad C \rightarrow B = C \ltimes E,$$

where $E$ denotes the $C$-$C$-bimodule $E = \text{Ext}^2_C(DC, C)$ and $C \ltimes E$ is the trivial extension.

This result allows one to define cluster-tilted algebras without using the cluster category. It is natural to ask how the module categories of $C$ and $B$ are related, and several results in this direction have been obtained, see for example [ABS2, ABS3, ABS4, BFPPT, BOW, DS].

The authors were supported by the NSF CAREER grant DMS-1254567 and by the University of Connecticut.
The Hochschild cohomology of the algebras $C$ and $B$ has been compared in [AR, ARS, ABIS, L].

In this paper, we use a new approach to study the relation between the module categories of a tilted algebra $C$ and its cluster-tilted algebra $B = C \ltimes E$, namely induction and coinduction.

The induction functor $- \otimes_C B$ and the coinduction functor $\text{Hom}_C(B, -)$ from $\text{mod} C$ to $\text{mod} B$ are defined whenever $C$ is a subring of $B$ which has the same identity. If we are dealing with algebras over a field $k$, we can, and usually do, write the coinduction functor as $D(B \otimes_C D -)$, where $D = \text{Hom}(-, k)$ is the standard duality.

Induction and coinduction are important tools in classical Representation Theory of Finite Groups. In this case, $B$ would be the group algebra of a finite group $G$ and $C$ the group algebra of a subgroup of $G$ (over a field whose characteristic is not dividing the group orders). In this situation, the algebras are semi-simple, induction and coinduction are the same functor, and this functor is exact.

For arbitrary rings, and even for finite dimensional algebras, the situation is not that simple. In general, induction and coinduction are not the same functor and, since the $C$-module $B$ is not projective (and not flat), induction and coinduction are not exact functors.

However, the connection between tilted algebras and cluster-tilted algebras is close enough so that induction and coinduction are interesting tools for the study of the relation between the module categories.

Induction and coinduction have been studied for split extension algebras in [AM, AZ], and we apply some of their results to our situation.

Our first main result is on the $C$-$C$-bimodule $E = \text{Ext}^2_C(DC, C)$ considering its right $C$-module structure $EC$ as well as its left $C$-module structure $CE$ but as a right $C$-module $D(CE)$. We show the following.

**Theorem 1.1.** If $C$ is a tilted algebra and $B$ is the corresponding cluster-tilted algebra, then

(a) $DE$ is a partial tilting and $\tau_C$-rigid $C$-module, and its corresponding induced module $DE \otimes B$ is a partial tilting and $\tau_B$-rigid $B$-module.

(b) $E$ is a partial cotilting and $\tau_C$-corigid $C$-module, and its corresponding coinduced module $D(B \otimes DE)$ is a partial cotilting and $\tau_B$-corigid $B$-module.

We think it would be an interesting problem to study the possible completions of these partial (co)-tilting modules and their endomorphism algebras.

Our second main result is on injective and projective resolutions. Since the induction functor sends projective $C$-modules $P_C$ to projective $B$-modules $P_B = P_C \otimes_C B$, and the coinduction functor sends injective $C$-modules $I_C$ to injective $B$-modules $I_B = D(B \otimes_C DI_C)$, we are able to construct certain resolutions in mod $B$ from corresponding resolutions in mod $C$. In particular, we have the following explicit construction of an injective resolution for each projective $B$-module. Here $\nu$ denotes the Nakayama functor and $\Omega^{-1}$ the cosyzygy.

**Theorem 1.2.** Let $C$ be a tilted algebra, $B$ the corresponding cluster-tilted algebra, $P_C$ a projective $C$-module and $P_B = P_C \otimes_C B$ the corresponding projective $B$-module. Let

$$
0 \rightarrow P_C \rightarrow I^0_C \rightarrow I^1_C \rightarrow \cdots \quad \text{and} \quad 0 \rightarrow P_C \otimes E \rightarrow I^0_C \rightarrow I^1_C \rightarrow \cdots
$$
be minimal injective presentations in \( \text{mod } C \), and let \( \tilde{I}_C \) be the injective \( C \)-module \( \tilde{I}_C = \nu \nu^{-1} \Omega^{-1} P_C \). Then

\[
0 \rightarrow P_B \rightarrow I^0_B \oplus \bar{I}^0_B \rightarrow \tilde{I}_B \oplus \bar{I}_B^1 \rightarrow 0
\]

is an injective resolution of \( P_B \) in \( \text{mod } B \).

As an immediate consequence, we obtain a new proof, which does not use cluster categories, of a result by Keller and Reiten \([KR]\).

**Corollary 1.3.** Cluster-tilted algebras are 1-Gorenstein.

The proof of the theorem uses both induction and coinduction, and it relies greatly on the particular structure of the bimodule \( E \).

Our third main result compares induction and coinduction with the well-known equivalence of categories \( \text{Hom}_{C_A}(T, -) : C_A/\text{add } \tau T \rightarrow \text{mod } B \) of Buan, Marsh and Reiten \([BMR]\). Here \( C_A \) denotes the cluster category. We show that induction commutes with this equivalence on the subcategory \( \mathcal{T}(T) \) given by the torsion subcategory determined by the tilting module \( T \),

\[
\mathcal{T}(T) = \{ M \in \text{mod } A \mid \text{Ext}^1_A(T, M) = 0 \}.
\]

We also show a similar statement for the coinduction functor using the torsion free subcategory \( \mathcal{F}(T) \) determined by \( T \),

\[
\mathcal{F}(T) = \{ M \in \text{mod } A \mid \text{Hom}_A(T, N) = 0 \}.
\]

We show the following.

**Theorem 1.4.** Let \( C \) be a tilted algebra and \( B \) the corresponding cluster-tilted algebra. Then

\[
\text{Hom}_{C_A}(T, M) \otimes_C B \cong \text{Hom}_{C_A}(T, M), \text{ for every } M \in \mathcal{T}(T),
\]

\[
D(B \otimes_C D\text{Ext}^1_A(T, M)) \cong \text{Ext}^1_{C_A}(T, M), \text{ for every } M \in \mathcal{F}(T).
\]

Let us point out that these formulas implicitly use the tilting theorem of Brenner and Butler \([BB]\).

Finally, we address the question which \( B \)-modules are actually induced or coinduced from a tilted algebra. We obtain the following results.

**Theorem 1.5.** Let \( B \) be a cluster-tilted algebra.

(a) If \( B \) is of finite representation type, then every \( B \)-module is induced and coinduced from some tilted algebra.

(b) If \( B \) is of arbitrary representation type, then every transjective \( B \)-module is induced or coinduced from some tilted algebra.

(c) If \( B \) is cluster concealed, then every \( B \)-module is induced or coinduced from some tilted algebra.

(d) If \( B \) is of tame representation type and such that there are no morphisms between indecomposable projective non-transjective modules, then every indecomposable \( B \)-module is induced or coinduced from some tilted algebra.

We remark that for general cluster-tilted algebras, there are indecomposable modules that are not induced and not coinduced. We think it would be interesting to study the structure of these modules.

The paper is organized as follows. We start by recalling some background on tilting theory in section 2 and reviewing general results on induction and coinduction in section 3.
In section 4, we study induction and coinduction from tilted to cluster-tilted algebras and prove Theorem 1.1. Section 5 is devoted to the construction of injective resolutions of projective $B$-modules and the proof of Theorem 1.2. The relation to cluster categories and the proof of Theorem 1.4 are contained in section 6, and in section 7 we study the question which $B$-modules are induced or coinduced from a tilted algebra.

2. Notation and Preliminaries

Throughout this paper all algebras are assumed to be basic, finite dimensional over an algebraically closed field $k$. Suppose $Q = (Q_0, Q_1)$ is a connected quiver without oriented cycles. By $kQ$ we denote the path algebra of $Q$. If $\Lambda$ is a $k$-algebra then denote by $\text{mod} \, \Lambda$ the category of finitely generated right $\Lambda$-modules and by $\text{ind} \, \Lambda$ a set of representatives of each isomorphism class of indecomposable right $\Lambda$-modules. Given $M \in \text{mod} \, \Lambda$, the projective dimension of $M$ in $\text{mod} \, \Lambda$ is denoted by $\text{pd}_\Lambda M$ and its injective dimension by $\text{id}_\Lambda M$. Let $\tau$ be the Auslander-Reiten translation. Also define $\Omega M$ to be the first syzygy and $\Omega^{-1} M$ the first cosyzygy of $M$. By $D$ we understand the standard duality functor $\text{Hom}_k(-, k)$. Finally, let $\nu = D\text{Hom}_\Lambda(-, \Lambda)$ be the Nakayama functor and $\nu^{-1} = \text{Hom}_\Lambda(D\Lambda, -)$ be the inverse Nakayama functor. For further details on representation theory we refer to [ASS, S].

2.1. Tilted algebras. Let $A$ be a hereditary algebra and let $T$ be a basic tilting $A$-module. Recall that $T$ is tilting if $\text{Ext}^1_A(T, T) = 0$ and the number of indecomposable direct summands of $T$ equals the number of isomorphism classes of simple $A$-modules. Then $C = \text{End}_A T$ is the corresponding tilted algebra. Consider the following full subcategories of $\text{mod} \, A$.

$$\mathcal{T}(T) = \{ M \in \text{mod} \, A \mid \text{Ext}^1_A(T, M) = 0 \}$$

$$\mathcal{F}(T) = \{ M \in \text{mod} \, A \mid \text{Hom}_A(T, M) = 0 \}$$

Then $(\mathcal{T}(T), \mathcal{F}(T))$ is a torsion pair in $\text{mod} \, A$ that determines another torsion pair $(\mathcal{X}(T), \mathcal{Y}(T))$ in $\text{mod} \, C$, where

$$\mathcal{X}(T) = \{ M \in \text{mod} \, C \mid M \otimes_C T = 0 \}$$

$$\mathcal{Y}(T) = \{ M \in \text{mod} \, C \mid \text{Tor}_1^C(M, T) = 0 \}.$$ 

For more details refer to [ASS, chapters VI, and VIII]. With this notation consider the following theorem due to Brenner and Butler.

**Theorem 2.1.** Let $A$ be a hereditary algebra, $T$ a tilting $A$-module, and $C = \text{End}_A T$. Then

(a) the functors $\text{Hom}_A(T, -)$ and $- \otimes_C T$ induce quasi-inverse equivalences between $\mathcal{T}(T)$ and $\mathcal{Y}(T)$;

(b) the functors $\text{Ext}^1_A(T, -)$ and $\text{Tor}_1^C(-, T)$ induce quasi-inverse equivalences between $\mathcal{F}(T)$ and $\mathcal{X}(T)$.

Moreover, for any $M \in \text{mod} \, A$ we have $\text{Tor}_1^C(\text{Hom}_A(T, M), T) = 0$ and $\text{Ext}_A^1(T, M) \otimes_C T = 0$, and for any $N \in \text{mod} \, C$ we have $\text{Hom}_A(T, \text{Tor}_1^C(N, T)) = 0$ and $\text{Ext}_A^1(T, N \otimes_C T) = 0$.

Let $\Lambda$ be a $k$-algebra, then let $\Gamma(\text{mod} \, \Lambda)$ denote the Auslander-Reiten quiver of $\text{mod} \, \Lambda$. A connected component of $\Gamma(\text{mod} \, \Lambda)$ is called regular if it contains neither projective nor injective modules. An indecomposable $\Lambda$-module is called regular if it belongs to a regular component of $\Gamma(\text{mod} \, \Lambda)$. There is a close relationship between the Auslander-Reiten quivers of a hereditary algebra and its tilted algebras. We shall need the following result.
Theorem 2.2. [ASS, p.330] Let $A$ be a representation-infinite hereditary algebra, $T$ be a preprojective tilting $A$-module, and $C = \text{End}_A T$. Then

(a) $T(T)$ contains all but finitely many nonisomorphic indecomposable $A$-modules, and any indecomposable $A$-module not in $T(T)$ is preprojective;
(b) the image under the functor $\text{Hom}_A(T, -)$ of regular $A$-modules yields all regular $C$-modules;
(c) the injective and projective dimension of all regular $C$-modules is at most one.

The following proposition describes several facts about tilted algebras, which we will use throughout the paper.

Proposition 2.3. Let $A$ be a hereditary algebra, $T$ a tilting $A$-module, and $C = \text{End}_A T$ the corresponding tilted algebra. Then

(a) $\text{gl.dim } C \leq 2$.
(b) For all $M \in \text{ind } C$ id$_C M \leq 1$ or pd$_C M \leq 1$.
(c) For all $M \in \mathcal{X}(T)$ id$_C M \leq 1$.
(d) For all $M \in \mathcal{Y}(T)$ pd$_C M \leq 1$.
(e) $(\mathcal{X}(T), \mathcal{Y}(T))$ is splitting, which means that every indecomposable $C$-module belongs either to $\mathcal{X}(T)$ or $\mathcal{Y}(T)$.
(f) $\mathcal{Y}(T)$ is closed under predecessors and $\mathcal{X}(T)$ is closed under successors.

There is also a precise description of injective modules in a tilted algebra in terms of the corresponding hereditary algebra.

Proposition 2.4. Let $A$ be a hereditary algebra, $T$ a tilting $A$-module, and $C = \text{End}_A T$. Let $T_1, \ldots, T_n$ be a complete set of pairwise nonisomorphic indecomposable direct summands of $T$. Assume that the modules $T_1, \ldots, T_m$ are projective, the remaining modules $T_{m+1}, \ldots, T_n$ are not projective, and $I_1, \ldots, I_m$ are indecomposable injective $A$-modules with $\text{soc } I_j \cong T_j/\text{rad } T_j$, for $j = 1, \ldots, m$. Then the $C$-modules

$$\text{Hom}_A(T, I_1), \ldots, \text{Hom}_A(T, I_m), \text{Ext}_A^1(T, T_{m+1}), \ldots, \text{Ext}_A^1(T, \tau T_n)$$

form a complete set of pairwise nonisomorphic indecomposable injective modules.

2.2. Cluster categories and cluster-tilted algebras. Let $A = kQ$ and let $\mathcal{D}^b(\text{mod } A)$ denote the derived category of bounded complexes of $A$-modules. The cluster category $\mathcal{C}_A$ is defined as the orbit category of the derived category with respect to the functor $\tau^1_{\mathcal{D}}[1]$, where $\tau_{\mathcal{D}}$ is the Auslander-Reiten translation in the derived category and $[1]$ is the shift. Cluster categories were introduced in [BMRRT], and in [CCS] for type $A$, and were further studied in [K], [KR], [A, P]. They are triangulated categories [K], that are 2-Calabi Yau and have Serre duality [BMRRT].

An object $T$ in $\mathcal{C}_A$ is called cluster-tilting if $\text{Ext}_{\mathcal{C}_A}^1(T, T) = 0$ and $T$ has $|Q_0|$ non-isomorphic indecomposable direct summands. The endomorphism algebra $\text{End}_{\mathcal{C}_A} T$ of a cluster-tilting object is called a cluster-tilted algebra [BMR].

The following theorem will be useful later.

Theorem 2.5. [BMR] If $T$ is a cluster-tilting object in $\mathcal{C}_A$, then $\text{Hom}_{\mathcal{C}_A}(T, -)$ induces an equivalence of categories $\mathcal{C}_A/\text{add}(\tau T) \to \text{mod } \text{End}_{\mathcal{C}_A} T$.
2.3. **Relation extensions.** Let $C$ be an algebra of global dimension at most two and let $E$ be the $C$-$C$-bimodule $E = \text{Ext}^2_C(\text{DC}, C)$. The **relation extension** of $C$ is the trivial extension algebra $B = C \ltimes E$, whose underlying $C$-module is $C \oplus E$, and multiplication is given by $(c, e)(c', e') = (cc', ce' + e c')$. Relation extensions where introduced in [ABS]. In the special case where $C$ is a tilted algebra, we have the following result.

**Theorem 2.6.** [ABS] Let $C$ be a tilted algebra. Then $B = C \ltimes \text{Ext}^2_C(\text{DC}, C)$ is a cluster-tilted algebra. Moreover all cluster-tilted algebras are of this form.

This shows that the tilted algebra $C$ is a subalgebra and a quotient of the cluster-tilted algebra $B$. In particular there exists a short exact sequence of right $B$-modules

$$(1) \quad 0 \longrightarrow E \xrightarrow{i} B_B \xrightarrow{\pi} C_C \longrightarrow 0.$$

2.4. **Slices and local slices.** Let $\Lambda$ be a $k$-algebra.

**Definition 2.7.** A **path** in $\text{mod} \Lambda$ with source $X$ and target $Y$ is a sequence of non-zero morphisms $X = X_0 \rightarrow X_1 \rightarrow \cdots \rightarrow X_s = Y$ where $X_i \in \text{mod} \Lambda$ for all $i$, and $s \geq 1$. A **path** in $\Gamma(\text{mod} \Lambda)$ with source $X$ and target $Y$ is a sequence of arrows $X = X_0 \rightarrow X_1 \rightarrow \cdots \rightarrow X_s = Y$ in the Auslander-Reiten quiver. In addition, such path is called **sectional** if for each $i$ with $0 < i < s$, we have $\tau_\Lambda X_{i+1} \neq X_{i-1}$.

**Definition 2.8.** A **slice** $\Sigma$ in $\Gamma(\text{mod} \Lambda)$ is a set of indecomposable $\Lambda$-modules such that

(i) $\Sigma$ is sincere.

(ii) Any path in $\text{mod} \Lambda$ with source and target in $\Sigma$ consists entirely of modules in $\Sigma$.

(iii) If $M$ is an indecomposable non-projective $\Lambda$-module then at most one of $M$, $\tau_\Lambda M$ belongs to $\Sigma$.

(iv) If $M \rightarrow S$ is an irreducible morphism with $M, S \in \text{ind} \Lambda$ and $S \in \Sigma$, then either $M$ belongs to $\Sigma$ or $M$ is non-injective and $\tau_{\Lambda}^{-1} M$ belongs to $\Sigma$.

Given an indecomposable $\Lambda$-module $Y$ in a connected component $\Gamma$ of $\Gamma(\text{mod} \Lambda)$ let

$\Sigma(\rightarrow Y) = \{ X \in \text{ind} \Lambda \mid \exists X \rightarrow \cdots \rightarrow Y \in \Gamma \text{ and every path from } X \text{ to } Y \text{ in } \Gamma \text{ is sectional} \}$

$\Sigma(Y \rightarrow) = \{ X \in \text{ind} \Lambda \mid \exists Y \rightarrow \cdots \rightarrow X \in \Gamma \text{ and every path from } Y \text{ to } X \text{ in } \Gamma \text{ is sectional} \}$

be two subquivers of $\Gamma$. Consider the following result due to Ringel.

**Proposition 2.9.** [R] Let $Y$ be an indecomposable sincere module in a standard, convex, and directed component. Then both $\Sigma(\rightarrow Y)$ and $\Sigma(Y \rightarrow)$ are slices. Moreover, a component that is preprojective or preinjective is standard, convex, and directed.

The existence of slices is used to characterize tilted algebras in the following way.

**Theorem 2.10.** [R] Let $C = \text{End}_A T$ be a tilted algebra. Then the class of $C$-modules $\text{Hom}_A(T, DA)$ forms a slice in $\text{mod} C$. Conversely, any slice in any module category is obtained in this way.

The following notion of local slices has been introduced in [ABS2] in the context of cluster-tilted algebras.

**Definition 2.11.** A **local slice** $\Sigma$ in $\Gamma(\text{mod} \Lambda)$ is a set of indecomposable $\Lambda$-modules inducing a connected full subquiver of $\Gamma(\text{mod} \Lambda)$ such that

(i) If $X \in \Sigma$ and $X \rightarrow Y$ is an arrow in $\Gamma(\text{mod} \Lambda)$ then either $Y \in \Sigma$ or $\tau Y \in \Sigma$.
(ii) If \( Y \in \Sigma \) and \( X \to Y \) is an arrow in \( \Gamma(\text{mod } \Lambda) \) then either \( X \in \Sigma \) or \( \tau^{-1}X \in \Sigma \).

(iii) For every sectional path \( X = X_0 \to X_1 \to \cdots \to X_s = Y \) in \( \Gamma(\text{mod } \Lambda) \) with \( X, Y \in \Sigma \) we have \( X_i \in \Sigma \), for \( i = 0, 1, \ldots, s \).

(iv) The number of indecomposables in \( \Sigma \) equals the number of nonisomorphic summands of \( T \), where \( T \) is a tilting \( \Lambda \)-module.

**Remark.** The definition of a local slice makes sense if we replace the algebra \( \Lambda \) by a cluster category \( C_A \), and then consider objects of \( C_A \) instead of \( \Lambda \)-modules.

There is a relationship between tilted and cluster-tilted algebras given in terms of slices and local slices.

**Theorem 2.12.** [ABS2] Let \( C \) be a tilted algebra and \( B \) be the corresponding cluster-tilted algebra. Then any slice in \( \text{mod } C \) embeds as a local slice in \( \text{mod } B \) and any local slice \( \Sigma \) in \( \text{mod } B \) arises in this way. Moreover, \( C = B/\text{Ann}_B \Sigma \).

The existence of local slices in a cluster-tilted algebra gives rise to the following definition. The unique connected component of \( \Gamma(\text{mod } B) \) that contains local slices is called the transjective component. In particular if \( B \) is of finite representation type then the transjective component is the entire Auslander-Reiten quiver of \( \text{mod } B \). In this case there is the following statement.

**Theorem 2.13.** [ABS2] Let \( B \) be a representation-finite cluster-tilted algebra. Then any indecomposable \( B \)-module lies on a local slice.

We end this section with a lemma that we will need later.

**Lemma 2.14.** Let \( \tilde{\Sigma} \) be a local slice in the cluster category \( C_A \). Then \( \Sigma = \text{Hom}_{C_A}(T, \tilde{\Sigma}) \) is a local slice in \( \text{mod } B \) if and only if \( \tilde{\Sigma} \) contains no summand of \( \tau_{C_A}T \).

**Proof.** \( \text{Hom}_{C_A}(T, -) : \tilde{\Sigma} \to \Sigma \) is a bijection if and only if \( \tilde{\Sigma} \) contains no summand of \( \tau_{C_A}T \). Now the statement follows from [ABS2] Lemma 17. \( \square \)

### 3. Induction and Coinduction Functors

In this section we define two functors called induction and coinduction and describe some general results about them. Suppose there are two \( k \)-algebras \( C \) and \( B \) with the property that \( C \) is a subalgebra of \( B \) and they share the same identity. Then there is a general construction via the tensor product, also known as extension of scalars, that sends a \( C \)-module to a particular \( B \)-module. We give a precise definition below.

**Definition 3.1.** Let \( C \) be a subalgebra of \( B \), such that \( 1_C = 1_B \), then

\[
\mathbb{D} : \text{mod } C \to \text{mod } B
\]

is called the *induction functor*, and dually

\[
\mathbb{D} : \text{mod } C \to \text{mod } B
\]

is called the *coinduction functor*. Moreover, given \( M \in \text{mod } C \) the corresponding *induced module* is defined to be \( M \otimes_C B \), and the *coinduced module* is defined to be \( \mathbb{D}(B \otimes_C DM) \).

First observe that both functors are covariant. The induction functor is right exact, while the coinduction functor is left exact. Now consider the following lemma.
Lemma 3.2. Let $C$ and $B$ be two $k$-algebras and $N$ a $C$-$B$-bimodule, then

$$M \otimes_C N \cong D\text{Hom}_C(M, DN)$$

as $B$-modules for all $M \in \text{mod } C$.

Proof. $M \otimes_C N \cong D\text{Hom}_k(M \otimes_C N, k) \cong D\text{Hom}_C(M, \text{Hom}_k(N, k)) \cong D\text{Hom}_C(M, DN)$. □

The next proposition describes an alternative definition of these functors, and we will use these two descriptions interchangeably.

Proposition 3.3. Let $C$ be a subalgebra of $B$ such that $1_C = 1_B$, then for every $M \in \text{mod } C$

(a) $M \otimes_C B \cong D\text{Hom}_C(M, DB)$.
(b) $D(B \otimes_C DM) \cong \text{Hom}_C(B, M)$.

Proof. Both parts follow from Lemma 3.2. □

Next we show some basic properties of these functors.

Proposition 3.4. Let $C$ be a subalgebra of $B$ such that $1_C = 1_B$. If $e$ is an idempotent then

(a) $(eC) \otimes_C B \cong eB$.
(b) $D(B \otimes_C Ce) \cong DBe$.

In particular, if $P(i)$ and $I(i)$ are indecomposable projective and injective $C$-modules at vertex $i$, then $P(i) \otimes_C B$ and $D(B \otimes_C DI(i))$ are respectively indecomposable projective and injective $B$-modules at vertex $i$.

Proof. Observe that $(eC) \otimes_C B = e(C \otimes_C B) \cong eB$, and similarly we have $D(B \otimes_C (Ce)) = D((B \otimes_C C)e) \cong DBe$. The rest of the proposition follows from above if we let $e = e_i$ be the primitive idempotent given by the constant path at vertex $i$. □

We can say more in the situation when $B$ is a split extension of $C$.

Definition 3.5. Let $B$ and $C$ be two algebras. We say $B$ is a split extension of $C$ by a nilpotent bimodule $E$ if there exists a short exact sequence of $B$-modules

$$0 \longrightarrow E \overset{i}{\longrightarrow} B \overset{\pi}{\longrightarrow} C \longrightarrow 0$$

where $\pi$ and $\sigma$ are algebra homomorphisms, such that $\pi\sigma = 1_C$, and $E = \ker \pi$ is nilpotent.

For example, relation extensions are split extensions.

If $B$ is a split extension of $C$ then $\sigma$ is injective, which means $C$ is a subalgebra of $B$. Also, $E$ is a $C$-$C$-bimodule, and we require $E$ to be nilpotent so that $1_B = 1_C$. Observe that $B \cong C \oplus E$ as $C$-modules, and there is an isomorphism of $C$-modules $M \otimes_C B \cong M \otimes_C C \oplus M \otimes_C E \cong M \oplus M \otimes_C E$. Similarly, $D(B \otimes_C DM) \cong M \oplus D(E \otimes_C DM)$ as $C$-modules. This shows that induction and coinduction of a module $M$ yields the same module $M$ plus possibly something else. The next proposition shows a precise relationship between a given $C$-module and its image under the induction and coinduction functors.

Proposition 3.6. Suppose $B$ is a split extension of $C$ by a nilpotent bimodule $E$, then for every $M \in \text{mod } C$ there exist two short exact sequences of $B$-modules:

(a) $0 \longrightarrow M \otimes_C E \longrightarrow M \otimes_C B \longrightarrow M \longrightarrow 0$.
(b) $0 \longrightarrow M \longrightarrow D(B \otimes_C DM) \longrightarrow D(E \otimes_C DM) \longrightarrow 0$. 
Proof. To show part (a) we apply $M \otimes_C -$ to the short exact sequence \ref{eq:2} and obtain the following long exact sequence

$\text{Tor}_1^C(M, C) \longrightarrow M \otimes_C E \longrightarrow M \otimes_C B \longrightarrow M \otimes_C C \longrightarrow 0$.

However, $\text{Tor}_1^C(M, C) = 0$ since $C$ is a projective $C$-module, so part (a) follows. Similarly, to show part (b) we apply $D(- \otimes_C DM)$ to sequence \ref{eq:2}. This yields a long exact sequence

$0 \longrightarrow D(C \otimes_C DM) \longrightarrow D(B \otimes_C DM) \longrightarrow D(E \otimes_C DM) \longrightarrow D\text{Tor}_1^C(C, DM)$.

The last term in the sequence is again zero, which shows part (b). \hfill \square

Thus, in this situation each module is a quotient of its induced module and a submodule of its coinduced module.

**Proposition 3.7.** Suppose $B$ is a split extension of $C$ by a nilpotent bimodule $E$, then for every $M, N \in \text{mod } C$

(a) $M \otimes_C B \cong N \otimes_C B$ if and only if $M \cong N$.

(b) $D(B \otimes_C DM) \cong D(B \otimes_C DN)$ if and only if $M \cong N$.

**Proof.** Part (a). Suppose $M \otimes_C B \cong N \otimes_C B$. Because $B$ is a split extension of $C$, it follows that $C$ has a left $B$-module structure. Thus, we have that $M \otimes_C B \otimes_B C \cong N \otimes_C B \otimes_B C$, which means $M \cong M \otimes_C C \cong N \otimes_C C \cong N$. The proof of part (b) is similar to that of part (a) and we omit it. \hfill \square

The next lemma describes a relationship between the Auslander-Reiten translations in $\text{mod } C$ and $\text{mod } B$, and induction and coinduction functors. This lemma together with the following theorem were shown in [AM].

**Lemma 3.8.** Suppose $B$ is a split extension of $C$ by a nilpotent bimodule, then for every $M \in \text{mod } C$

(a) $\tau_B(M \otimes_C B) \cong D(B \otimes_C D(\tau_C M))$.

(b) $\tau_B^{-1} D(B \otimes_C DM) \cong (\tau_C^{-1} M) \otimes_C B$.

**Theorem 3.9.** Suppose $B$ is a split extension of $C$ by a nilpotent bimodule $E$ and $T \in \text{mod } C$, then

(a) $T \otimes_C B$ is a (partial) tilting $B$-module if and only if $T$ is a (partial) tilting $C$-module, $\text{Hom}_C(T \otimes_C E, \tau_C T) = 0$ and $\text{Hom}_C(DE, \tau_C T) = 0$.

(b) $D(B \otimes_C DT)$ is a (partial) cotilting $B$-module if and only if $T$ is a (partial) cotilting $C$-module, $\text{Hom}_C(\tau_C^{-1} T, D(E \otimes_C DT)) = 0$ and $\text{Hom}_C(\tau_C^{-1} T, E) = 0$.

4. **Induced and Coinduced Modules in Cluster-Tilted Algebras**

In this section we develop properties of the induction and coinduction functors particularly when $C$ is an algebra of global dimension at most two and $B = C \ltimes E$ is the trivial extension of $C$ by the $C$-$C$-bimodule $E = \text{Ext}^2_C(\text{DC}, C)$. In the specific case when $C$ is also a tilted algebra, $B$ is the corresponding cluster-tilted algebra. Some of the results in this section only hold when $C$ is tilted, but many hold in a more general situation when $\text{gl.dim } C \leq 2$, and we make that distinction clear in the assumptions of each statement. However, throughout this section we always assume $E = \text{Ext}^2_C(\text{DC}, C)$ and a tensor product $\otimes$ is a tensor product over $C$. The main result of this section holds when $C$ is a tilted algebra. It says that $DE$ is
a partial tilting and $\tau_C$-rigid $C$-module, and the corresponding induced module $DE \otimes B$ is a partial tilting and $\tau_B$-rigid $B$-module.

**Proposition 4.1.** Let $C$ be an algebra of global dimension at most 2. Then

(a) $E \cong \tau^{-1}\Omega^{-1}C$.
(b) $DE \cong \tau \Omega DC$.
(c) $M \otimes E \cong \tau^{-1}\Omega^{-1}M$.
(d) $D(E \otimes DM) \cong \tau \Omega M$.

**Proof.** Since the global dimension of $C$ is at most 2, we have $\text{id}_C \Omega^{-1}M \leq 1$ (resp. $\text{pd}_C \Omega M \leq 1$) for all $C$-modules $M$. Therefore, when applying the Auslander-Reiten formula below, we obtain the following corollary for any $C$-module $M$. Here we present a new proof using induction and coinduction functors.

Part (a). Suppose $E = \text{Ext}^2_C(DC, C) \cong \text{Ext}^1_C(DC, \Omega^{-1}C) \cong D\text{Hom}_C(\tau^{-1}\Omega^{-1}C, DC) \cong \tau^{-1}\Omega^{-1}C$.

Part (b). $DE = D\text{Ext}^2_C(DC, C) \cong D\text{Ext}^1_C(\Omega DC, C) \cong \text{Hom}_C(C, \tau \Omega DC) \cong \tau \Omega DC$.

Part (c). Using Lemma 3.2 we have $M \otimes E \cong D\text{Hom}_C(M, DE)$, which in turn by part (b) is isomorphic to $D\text{Hom}_C(M, \tau \Omega DC)$. Then, we have the following chain of isomorphisms $M \otimes E \cong D\text{Hom}_C(M, \tau \Omega DC) \cong \text{Ext}^1_C(\Omega DC, M) \cong \text{Ext}^2_C(DC, M) \cong \text{Ext}^1_C(\Omega^{-1}M, DC) \cong D\text{Hom}_C(\tau^{-1}\Omega^{-1}M, DC) \cong \tau^{-1}\Omega^{-1}M$. Part (d) can be shown in a similar manner as above. □

**Proposition 4.2.** Let $C$ be an algebra of global dimension at most 2, and let $B = C \times E$. Suppose $M \in \text{mod } C$, then

(a) $\text{id}_C M \leq 1$ if and only if $M \otimes B \cong M$.
(b) $\text{pd}_C M \leq 1$ if and only if $D(B \otimes DM) \cong M$.

**Proof.** Part (a). Recall that $M \otimes B \cong M \oplus M \otimes E$ as $C$-modules. Therefore, it suffices to show that $M \otimes E = 0$ if and only if $\text{id}_C M \leq 1$. Proposition 4.1(c) implies that $M \otimes E \cong \tau^{-1}\Omega^{-1}M$, which is zero if and only if $\text{id}_C M \leq 1$.

Part (b). Similarly it suffices to show that $D(E \otimes DM) = 0$ if and only if $\text{pd}_C M \leq 1$. However, Proposition 4.1(d) implies that $D(E \otimes DM) \cong \tau \Omega M$, which again is zero if and only if $\text{pd}_C M \leq 1$. □

As a consequence of this proposition and Lemma 3.8 we obtain the following corollary, which says that a slice in a tilted algebra together with its $\tau$ and $\tau^{-1}$-translates fully embeds in the cluster-tilted algebra. This result was already shown in [ABS4] relying on the main theorem of [AZ]. Here we present a new proof using induction and coinduction functors.

**Corollary 4.3.** Let $C$ be a tilted algebra and $B$ the corresponding cluster-tilted algebra. Let $\Sigma$ be a slice in $\text{mod } C$ and $M$ a module in $\Sigma$. Then

(a) $\tau_C M \cong \tau_B M$.
(b) $\tau_C^{-1} M \cong \tau_B^{-1} M$.

**Proof.** We show part (a) and the proof of part (b) is similar. Since the module $M$ lies on a slice in $\text{mod } C$ then $\text{pd}_C M \leq 1$ and $\text{id}_C M \leq 1$. By Lemma 3.8(a) we have the following isomorphism

$$\tau_B(\text{END}_C B) \cong D(B \otimes C \text{D}(\text{END}_C M)).$$

It follows from Proposition 4.2(a) that the left hand side is isomorphic to $\tau_B M$. It remains to show that the right hand side is isomorphic to $\tau_C M$. We may suppose without loss of generality that $C = \text{End}_A T$ and $\Sigma = \text{Hom}_A(T, DA)$ lies in $\mathcal{Y}(T)$. Hence, in particular
$M \in \mathcal{Y}(T)$. Proposition 2.3(f) implies that $\tau_C M \in \mathcal{Y}(T)$, so part (d) of the same proposition shows that $\text{pd}_C \tau_C M \leq 1$. Therefore, $D(B \otimes_C D(\tau_C M)) \cong \tau_C M$ by Proposition 4.2(b), and this finishes the proof.

Lemma 4.4. Let $C$ be an algebra of global dimension 2. Then for all $M \in \text{mod} C$

(a) $\text{pd}_C N = 2$ for all nonzero $N \in \text{add} M \otimes E$.
(b) $\text{id}_C N = 2$ for all nonzero $N \in \text{add} D(E \otimes DM)$.

Proof. Part (a). By Proposition 4.1(c), $M \otimes E \cong \tau^{-1} \Omega^{-1} M$, which is nonzero if and only if $\text{id}_C M = 2$. Now, consider a minimal injective resolution of $M$ and $\Omega^{-1} M$

$$0 \longrightarrow M \longrightarrow I^0 \overset{\pi}{\longrightarrow} I^1 \longrightarrow I^2 \longrightarrow 0.$$  

Apply $\nu^{-1}$ to find a minimal projective resolution of $\tau^{-1} \Omega^{-1} M$.

$$0 \longrightarrow \nu^{-1} \Omega^{-1} M \longrightarrow \nu^{-1} I^1 \longrightarrow \nu^{-1} I^2 \longrightarrow \tau^{-1} \Omega^{-1} M \longrightarrow 0.$$  

Since $C$ has global dimension two, $\nu^{-1} \Omega^{-1} M$ is a projective $C$-module. It remains to show that it is nonzero. By definition $\nu^{-1} \Omega^{-1} M = \text{Hom}_C(DC, \Omega^{-1} M)$, which is nonzero since we have a nonzero map $\pi$. Finally, observe that the argument above holds if we replace $\tau^{-1} \Omega^{-1} M$ by a nonzero direct summand of $\tau^{-1} \Omega^{-1} M$. This completes the proof. Part (b) can be shown in a similar manner as above.

Lemma 4.5. Let $C$ be a tilted algebra. Then for all $M \in \text{mod} C$

(a) $\text{id}_C M \otimes E \leq 1$.
(b) $\text{pd}_C D(E \otimes DM) \leq 1$.

Proof. Part (a) follows from Lemma 4.4(a) and Proposition 2.3(b). Similarly, part (b) follows from Lemma 4.4(b) and Proposition 2.3(b).

Proposition 4.6. Let $C$ be a tilted algebra. Then

(a) $E \otimes E = 0$.
(b) $D(E \otimes D(DE)) = 0$.

Proof. Part (a). Proposition 4.1(c) implies that $E \otimes E \cong \tau^{-1} \Omega^{-1} E$, but this is zero since $\text{id}_C E \leq 1$, by Lemma 4.5(a) with $M = C$. Part (b) follows directly from part (a).

Remark. The above proposition does not hold if $C$ has global dimension 2, but is not tilted. For example, consider an algebra $C$ given by the following quiver with relations.

$$1 \overset{\alpha}{\longrightarrow} 2 \overset{\beta}{\longrightarrow} 3 \overset{\gamma}{\longrightarrow} 4 \overset{\delta}{\longrightarrow} 5 \quad \quad \alpha \beta = \gamma \delta = 0.$$  

The Auslander-Reiten quiver of $C$ is the following.

```
1 --\alpha\rightarrow 2 --\beta\rightarrow 3 --\gamma\rightarrow 4 --\delta\rightarrow 5
|        |        |        |        |
5 ----| 4 ----| 3 ----| 2 ----|
|        |        |        |        |
2 \sim| 3 \sim| 4 \sim| 1 \sim|
```

```
Here $E = S(1) \oplus S(3)$, where $S(i)$ is the simple module at vertex $i$. Hence, $E \otimes E \cong \tau^{-1}\Omega^{-1}(S(1) \oplus S(3)) = S(1)$.

The following lemma is used throughout the paper.

**Lemma 4.7.** Let $C$ be an algebra of global dimension at most 2, then

(a) $\text{Ext}^1_C(E, C) = 0$.
(b) $\text{Ext}^1_C(DC, DE) = 0$.
(c) $\text{Ext}^1_C(E, E) = 0$.
(d) $\text{Ext}^1_C(DE, DE) = 0$.

**Proof.** We will show parts (a) and (c), and the rest of the lemma can be proven similarly. Part (a). By Proposition 4.1(a), we see that $\text{Ext}^1_C(E, C) \cong \text{Ext}^1_C(\tau^{-1}\Omega^{-1}C, C)$, which in turn by the Auslander-Reiten formula is isomorphic to $D\text{Hom}_C(C, \Omega^{-1}C)$. Let $i : C \rightarrow I$ be an injective envelope of $C$, thus we have the following short exact sequence

$$0 \rightarrow C \xrightarrow{i} I \xrightarrow{\pi} \Omega^{-1}C \rightarrow 0.$$  

Applying $\text{Hom}_C(C, -)$ to this sequence we obtain an exact sequence

$$0 \rightarrow \text{Hom}_C(C, C) \rightarrow \text{Hom}_C(C, I) \xrightarrow{\pi_*} \text{Hom}_C(C, \Omega^{-1}C) \rightarrow \text{Ext}^1_C(C, C).$$

However, $\text{Ext}^1_C(C, C) = 0$ shows that $\pi_*$ is surjective. This implies that every morphism from $C$ to $\Omega^{-1}C$ factors through the injective $I$. Thus, $\text{Hom}_C(C, \Omega^{-1}C) = 0$, and this shows part (a).

Part (c). As above observe that $\text{Ext}^1_C(E, E) \cong D\text{Hom}_C(E, \Omega^{-1}C)$. Applying $\text{Hom}_C(E, -)$ to the sequence (3) we get an exact sequence

$$0 \rightarrow \text{Hom}_C(E, C) \rightarrow \text{Hom}_C(E, I) \xrightarrow{\pi_{**}} \text{Hom}_C(E, \Omega^{-1}C) \rightarrow \text{Ext}^1_C(E, C).$$

But then by part (a) we have $\text{Ext}^1_C(E, I) = 0$, which shows that $\pi_{**}$ is surjective. Thus $\text{Hom}_C(E, \Omega^{-1}C) = 0$, and this completes the proof of part (c). \hfill \Box

**Corollary 4.8.** If the global dimension of $C$ is at most two, then both $E \oplus C$ and $DE \oplus DC$ are rigid modules.

**Proof.** Observe that $\text{Ext}^1_C(E \oplus C, E \oplus C) \cong \text{Ext}^1_C(E, E \oplus C) \oplus \text{Ext}^1_C(C, E \oplus C)$. The first summand is zero because of Lemma 4.7 and the second is zero because $C$ is projective. The proof of the rigidity of $DE \oplus DC$ is similar. \hfill \Box

The following theorem is the main result of this section. Following [AIR], we say that a $\Lambda$-module $M$ is $\tau_{\Lambda}$-rigid if $\text{Hom}_\Lambda(M, \tau_{\Lambda}M) = 0$.

**Theorem 4.9.** If $C$ is a tilted algebra and $B$ is the corresponding cluster-tilted algebra, then

(a) $DE$ is a partial tilting and $\tau_C$-rigid $C$-module, and its corresponding induced module $DE \otimes B$ is a partial tilting and $\tau_B$-rigid $B$-module.

(b) $E$ is a partial cotilting and $\tau_C$-corigid $C$-module, and its corresponding coinduced module $D(B \otimes DE)$ is a partial cotilting and $\tau_B$-corigid $B$-module.

**Proof.** We show part (a), and the proof of part (b) is similar. First let us show that $DE$ is a partial tilting and $\tau_C$-rigid $C$-module. Because $C$ is tilted, Lemma 4.5(b) implies that $\text{pd}_C DE \leq 1$, but also $DE$ is rigid by Lemma 4.7(d). This shows that $DE$ is a partial tilting $C$-module. On the other hand, by Lemma 4.4(b), all nonzero indecomposable summands of
DE have injective dimension 2. Thus, \(pd_C \leq 1\), by Proposition 2.3(b). So, applying the Auslander-Reiten formula we have \(\text{Hom}_C(\text{DE}, \tau_C \text{DE}) \cong D\text{Ext}_C^1(\text{DE}, \text{DE}) = 0\), where the last step follows from Lemma 4.7(d). This shows that \(\text{DE}\) is \(\tau_C\)-rigid.

Now, it remains to shows that \(\text{DE} \otimes B\) is a partial tilting and \(\tau_B\)-rigid \(B\)-module. First we show that \(\text{DE} \otimes B\) is partial tilting. From above we know that \(\text{DE}\) is a partial tilting \(C\)-module, thus by Theorem 3.9 it suffices to show that \(\text{Hom}_C(\text{DE} \otimes_C E, \tau_C \text{DE}) = 0\) and \(\text{Hom}_C(\text{DE}, \tau_C \text{DE}) = 0\). The second identity follows from the work above, so we need to show the first identity. Observe that by Lemma 4.4(a), \(pd_C \text{DE} \otimes E = 2\). Then Proposition 2.3 implies that \(\text{DE} \otimes E \in X(\text{T})\). Similarly, by Lemma 4.4(b), \(\text{id}_C \text{DE} = 2\), so Proposition 2.3 implies that \(\text{DE} \in Y(\text{T})\). However, by Proposition 2.3(f), \(Y(\text{T})\) is closed under predecessors, which means \(\tau_C \text{DE} \in Y(\text{T})\). By definition of a torsion pair there are no nonzero morphisms from \(X(\text{T})\) to \(Y(\text{T})\), so \(\text{Hom}_C(\text{DE} \otimes E, \tau_C \text{DE}) = 0\). This shows that \(\text{DE} \otimes B\) is a partial tilting \(B\)-module.

Now we show that \(\text{DE} \otimes B\) is \(\tau_B\)-rigid, that is \(\text{Hom}_B(\text{DE} \otimes B, \tau_B(\text{DE} \otimes B)) = 0\). First observe that Lemma 3.8(a) yields \(\tau_B(\text{DE} \otimes B) \cong D(B \otimes D \tau_C \text{DE})\), which in turn by Proposition 4.2(b) is isomorphic to \(\tau_C \text{DE}\). Let \(f \in \text{Hom}_B(\text{DE} \otimes B, \tau_C \text{DE})\). Then we have the following diagram, whose top row is the short exact sequence of Proposition 3.6(a).

\[
\begin{array}{ccc}
0 & \rightarrow & \text{DE} \otimes E \\
& i_* & \downarrow f \\
& \text{DE} \otimes B \\
& \pi_* & \downarrow g \\
& \text{DE} & \rightarrow \tau_C \text{DE} & 0
\end{array}
\]

Observe that \(fi_* \in \text{Hom}_C(\text{DE} \otimes E, \tau_C \text{DE})\), which is zero by our calculation above. Next, the universal property of \(\text{coker} i_*\) implies that there exists \(g \in \text{Hom}_C(\text{DE}, \tau_C \text{DE})\) such that \(g\pi_* = f\). However, we know that \(\text{DE}\) is \(\tau_C\)-rigid, which implies that \(g = 0\). This means \(f = 0\). Thus, we conclude that \(\text{DE} \otimes B\) is \(\tau_B\)-rigid. \(\square\)

**Remark.** Unlike \(\text{DE}\), the \(C\)-module \(E\) is not \(\tau_C\)-rigid, that is \(\text{Hom}_C(E, \tau_C E) \neq 0\). Consider, for example, the tilted algebra \(C\) given by the following quiver with relations.

\[
\begin{align*}
1 & \rightarrow 2 \\
\downarrow \delta & \downarrow \gamma \\
1 & \rightarrow 3 \\
\downarrow \beta & \downarrow \delta \\
3 & \rightarrow 4
\end{align*}
\]

\[
\delta = \gamma \beta = 0.
\]

Here \(E = \frac{1}{2} \oplus \frac{4}{3}\) and \(\tau_C E = \frac{4}{1} \oplus \frac{4}{1}\).

5. **Injective Resolutions**

In this section we construct an explicit injective resolution of an arbitrary projective \(B\)-module in a cluster-tilted algebra \(B\) using only induction and coinduction functors applied to modules over a tilted algebra \(C\). This resolution is described completely in terms of \(C\)-modules and has length at most one. We start by showing preliminary results that lead to the main theorem. Most of these statements are also true when the global dimension of \(C\) is at most 2 and we make that distinction clear.
Lemma 5.1. Let $\text{gl.dim } C = 2$ and $M \in \text{mod } C$. Suppose that $\text{id}_C M = 2$, and that

$$0 \longrightarrow M \xrightarrow{i_0} I^0_C \xrightarrow{i_2} I^1_C \xrightarrow{i_3} I^2_C \longrightarrow 0$$

is a minimal injective resolution of $M$. Then there is a commutative diagram with exact rows

$$0 \longrightarrow M \xrightarrow{i_0} I^0_C \xrightarrow{i_1} \Omega^{-1}M \longrightarrow 0$$

where $\tilde{I}_C = \nu \nu^{-1} \Omega^{-1} M$ is an injective $C$-module.

Proof. Consider the diagram below. The injective resolution of $M$ also gives a minimal injective resolution of $\Omega^{-1}M$, which is shown in the top row of the diagram. Then we apply the inverse Nakayama functor $\nu^{-1} = \text{Hom}_C(DC, -)$ to this resolution and obtain a projective presentation of $\tau^{-1} \Omega^{-1} M$ in the second row. First, note that $\nu^{-1} \Omega^{-1} M = \text{Hom}_C(DC, \Omega^{-1} M)$ is nonzero, because it contains the nonzero map $i_1$. Also, the global dimension of $C$ is two, which means that $\nu^{-1} \Omega^{-1} M$ is projective and we actually have a projective resolution of $\tau^{-1} \Omega^{-1} M$.

Next we apply the Nakayama functor $\nu = D\text{Hom}_C(-, C)$ to the projective resolution of $\Omega^{-1} \tau^{-1} M$, and obtain an injective presentation of $\tau \Omega^{-1} \Omega^{-1} M$ in the third row of the diagram. Observe that $\nu \Omega^{-1} \Omega^{-1} M = \nu \text{Im}(\nu^{-1} i_3) = \text{Im}(\nu \nu^{-1} i_3) = \text{Im} i_3 = I^2_C$.

Let $g_0 = \nu \nu^{-1} i_1$. By commutativity in the diagram below, we see that $i_4 \pi_1 g_0 = i_2 = i_4 i_1$. Since $i_4$ is injective, we conclude $\pi_1 g_0 = i_1$. This shows that we have two short exact sequences as in the statement of the lemma and that the second square in the diagram is commutative. Then by the universal property of $\ker \pi_1$ there exists $g_1 \in \text{Hom}_C(M, \tau \Omega^{-1} \Omega^{-1} M)$ that makes the first square commute.
**Proposition 5.2.** Let $\text{gl.dim} \, C \leq 2$ and $E = \text{Ext}_C^2(DC, C)$, then for every $M \in \text{mod} \, C$

$$M \otimes E \cong \text{Hom}_C(E, M \otimes E) \otimes E.$$  

**Proof.** Observe that by Proposition 4.1(c) the left hand side of the statement above is isomorphic to $\tau^{-1}\Omega^{-1}M$. Now consider the right hand side

$$\text{Hom}_C(E, M \otimes E) \otimes E \cong D(E \otimes D(M \otimes E)) \otimes E \quad \text{by Lemma 3.2}$$

$$\cong \tau\Omega(M \otimes E) \otimes E \quad \text{by Proposition 4.1(d)}$$

$$\cong \tau\Omega^{-1}\Omega^{-1}M \otimes E \quad \text{by Proposition 4.1(c)}$$

$$\cong \tau^{-1}\Omega^{-1}\tau\Omega^{-1}\Omega^{-1}M \quad \text{by Proposition 4.1(c)}.$$ 

Therefore, it suffices to show that $\tau^{-1}\Omega^{-1}M \cong \tau^{-1}\Omega^{-1}\tau\Omega^{-1}\Omega^{-1}M$. If $\text{id}_C M \leq 1$ then both sides are zero and the statement follows. If $\text{id}_C M = 2$, then by Lemma 5.1 we have a short exact sequence

$$0 \rightarrow \tau\Omega^{-1}\Omega^{-1}M \xrightarrow{\pi_0} \tilde{I}_C \rightarrow \Omega^{-1}M \rightarrow 0.$$ 

Next we construct the following commutative diagram

$$0 \rightarrow \tau\Omega^{-1}\Omega^{-1}M \rightarrow I \rightarrow \Omega^{-1}\tau\Omega^{-1}\Omega^{-1}M \rightarrow 0$$

$$0 \rightarrow \tau\Omega^{-1}\Omega^{-1}M \xrightarrow{\pi_0} \tilde{I}_C \rightarrow \Omega^{-1}M \rightarrow 0$$

where $I$ is an injective envelope of $\tau\Omega^{-1}\Omega^{-1}M$. The map $i$ exists and is a monomorphism by the properties of an injective envelope; $j$ exists by the universal property of the cokernel. Moreover, $\tilde{I}_C \cong i(I) \oplus I'$, where $I'$ is some injective $C$-module. By commutativity $\text{Im} \, \pi_0 \subset i(I)$, which implies that $\Omega^{-1}M \cong I' \oplus \Omega^{-1}\tau\Omega^{-1}\Omega^{-1}M$. Hence, $\tau^{-1}\Omega^{-1}M \cong \tau^{-1}\Omega^{-1}\tau\Omega^{-1}\Omega^{-1}M$. \qed

To simplify the notation we will write $I_C$ for an injective $C$-module, and $I_B$ for the corresponding injective $B$-module, that is $I_B = D(B \otimes DI_C)$. Also, the morphisms in the statements of the proceeding lemmas will be used in the proof of the main theorem, so we keep the notation consistent throughout this section.

**Lemma 5.3.** Suppose $P_C$ is a projective module over a tilted algebra $C$ such that $\text{id}_C P_C = 2$ with an injective envelope $0 \rightarrow P_C \xrightarrow{i_0} I_C$. Then there is a commutative diagram with exact rows

$$0 \rightarrow P_C \xrightarrow{(j_0, i_0) \, g_1} I_B \oplus \tau\Omega^{-1}\Omega^{-1}P_C \xrightarrow{(\alpha, -l_1 \pi_0)} \tilde{I}_B \rightarrow 0$$

$$0 \rightarrow I_C \xrightarrow{(j_0 \, g_0)} I_B \oplus \tilde{I}_C \xrightarrow{(\alpha, -l_1)} \tilde{I}_B \rightarrow 0$$

where $\tilde{I}_C = \nu\nu^{-1}\Omega^{-1}P_C$ is the injective $C$-module of Lemma 5.1.

**Proof.** By Lemma 5.1 there is a short exact sequence

$$0 \rightarrow P_C \xrightarrow{(i_0 \, g_1)} I_C \oplus \tau\Omega^{-1}\Omega^{-1}P_C \xrightarrow{(g_0, -\pi_0)} \tilde{I}_C \rightarrow 0.$$
We will apply the coinduction functor $\text{Hom}_C(B, -)$ to this sequence, but first observe that using Proposition 4.1(d) we have $\tau \Omega \tau^{-1} \Omega^{-1} P_C \cong D(E \otimes D \tau^{-1} \Omega^{-1} P_C)$. Since $C$ is tilted, Lemma 4.5(b) shows that the projective dimension of $\tau \Omega \tau^{-1} \Omega^{-1} P_C$ is strictly less than 2, and Proposition 4.2(b) implies that both $P_C$ and $\tau \Omega \tau^{-1} \Omega^{-1} P_C$ do not change under coinduction. Also, there is a $C$-module isomorphism $\text{Ext}^1_C(B, P_C) \cong \text{Ext}^1_C(C \oplus E, P_C) = 0$ by Corollary 4.8.

Hence, coinducing the sequence above we obtain the following short exact sequence.

$$0 \longrightarrow P_C \xrightarrow{(i_0, j_0)} I_B^0 \oplus \tau \Omega \tau^{-1} \Omega^{-1} P_C \xrightarrow{(\alpha, -l_1 \pi_0)} \tilde{I}_B \longrightarrow 0$$

Here, $\alpha$ is the coinduced morphism from $g_0$, and $l_1, j_0$ are the inclusions as in Proposition 3.6(b), such that there is a commutative diagram

$$
\begin{array}{ccc}
0 & \longrightarrow & I_C^0 \\
& \downarrow & \downarrow \alpha \\
0 & \longrightarrow & I_C \\
\end{array}
$$

So far we have constructed the top short exact sequence as in the statement of the lemma. It suffices to show that the bottom row is exact and that the diagram is commutative. First observe that the second square commutes trivially and the first one commutes because $\pi_0 g_1 = g_0 i_0$ by Lemma 5.1. Next, note that the bottom row is exact at $I_B^0$, because $j_0$ is injective, and it is exact at $\tilde{I}_B$, because the diagram is commutative.

Thus it remains to show that $\text{Im}(j_0) = \ker(\alpha, -l_1)$. To show the forward inclusion consider $(\alpha, -l_1)(j_0) = \alpha j_0 - l_1 g_0$ which is zero by diagram (4). Now suppose $\alpha(a) - l_1(b) = 0$ for some $a \in I_C^0$ and $b \in I_C$. By Lemma 5.1 there exists $d \in I_C^0$ such that $i_1(d) = \pi_1(b)$. Then $\pi_1 g_0(d) = i_1(d) = i_1(b)$ or equivalently $\pi_1(b - g_0(d)) = 0$. Again Lemma 5.1 implies that there exists $c \in \tau \Omega \tau^{-1} \Omega^{-1} P_C$ such that $\pi_0(c) = b - g_0(d)$. Now we have $\alpha(a) = l_1(b) = l_1 \pi_0(c) + g_0(d) = l_1 \pi_0(c) + \alpha j_0(d)$, where the last identity follows from diagram (4), so $\alpha(a - j_0(d)) = l_1 \pi_0(c) = 0$. Using the fact that the top row in our diagram is exact we can find $p \in P_C$ such that $j_0 i_0(p) = a - j_0(d)$ and $g_1(p) = c$. Finally, $i_0(p) + d \in I_C^0$ and $(j_0)(i_0(p) + d) = (\delta_0)$ since $g_0 i_0 = \pi_0 g_1$. This shows the reverse inclusion and completes the proof of the lemma.

**Lemma 5.4.** Let $\text{gl.dim } C = 2$. Suppose $P_C$ is a projective $C$-module with an injective envelope $0 \rightarrow P \xrightarrow{i_0} I_C^0$ and $\text{id}_C P = 2$. Then there exists a commutative diagram with exact rows

$$
\begin{array}{ccc}
0 & \longrightarrow & P_B \\
| & | & | \\
0 & \longrightarrow & I_C^0 \\
\end{array} \quad \begin{array}{ccc}
P_C \oplus \tau \Omega \tau^{-1} \Omega^{-1} P_C \otimes B & \xrightarrow{(g_1, -\delta_1)} & \tau \Omega \tau^{-1} \Omega^{-1} P_C \\
| & \downarrow & \downarrow \tau_0 \\
I_C^0 \oplus \tau \Omega \tau^{-1} \Omega^{-1} P_C \otimes B & \xrightarrow{(g_0, -\pi_0 \delta_1)} & \tilde{I}_C \\
\end{array} \quad 0
$$

where $\tilde{I}_C = \nu \nu^{-1} \Omega^{-1} P_C$ is the injective $C$-module of Lemma 5.1 and $P_B = P_C \otimes B$ is the corresponding projective $B$-module.
Proof. By Lemma 5.1 there is a short exact sequence

\[ 0 \rightarrow P_C \xrightarrow{(i_0 \, g_1)} I_C^0 \oplus \tau \Omega^{-1} \Omega^{-1} P_C \xrightarrow{(g_0, -\pi_0)} I_C \rightarrow 0. \]

We will apply the induction functor $D \text{Hom}_C(-, DB)$ to this sequence. Since $I_C^0$ and $I_C$ are injective, Proposition 4.2(a) implies that these modules do not change under induction. Also, there is a $C$-module isomorphism $\text{Ext}_C^1(I_C, DB) \cong \text{Ext}_C^1(I_C, DC \oplus DE) = 0$, by Corollary 4.8. Hence, inducing the sequence above we obtain the following short exact sequence.

\[ 0 \rightarrow P_B \xrightarrow{(i_0 u_1 \, g_2)} I_C^0 \oplus \tau \Omega^{-1} \Omega^{-1} P_C \otimes B \xrightarrow{(g_0, -\pi_0 \delta_1)} I_C \rightarrow 0. \]

Here, $g_2$ is the image of $g_1$ under the induction functor, and $\delta_1, u_1$ are projections as in Proposition 3.6(a), such that there is the following commutative diagram

\[
\begin{array}{ccc}
P_B & \xrightarrow{u_1} & P_C & \xrightarrow{0} \\
\downarrow{g_2} & & \downarrow{g_1} & \\
\tau \Omega^{-1} \Omega^{-1} P_C \otimes B & \xrightarrow{\delta_1} & \tau \Omega^{-1} \Omega^{-1} P_C & \xrightarrow{0} \\
\end{array}
\]

Thus we have constructed the bottom row as in the conclusion of the lemma. It suffices to show that the top row is exact and that the diagram is commutative. First observe that the first square commutes trivially and the second one commutes because $\pi_0 g_1 = g_0 i_0$, by Lemma 5.1. Next, note that the top row is exact at $P_B$ by commutativity of the diagram and it is exact at $\tau \Omega^{-1} \Omega^{-1} P_C$ because $\delta_1$ is surjective.

Therefore, it remains to show that $\text{Im}(u_2) = \ker(\gamma, -\delta_1)$. The forward inclusion holds, since $(\gamma, -\delta_1)(u_2) = g_1 u_1 - \delta_1 g_2 = 0$, by diagram (5). Now suppose that $g_1(a) - \delta_1(b) = 0$ for some $a \in P_C$ and $b \in \tau \Omega^{-1} \Omega^{-1} P_C \otimes B$. Applying $\pi_0$ to both sides we obtain $\pi_0 g_1(a) - \pi_0 \delta_1(b) = 0$. By commutativity. Since the bottom row is exact we can find $p \in P_B$ such that $i_0 u_1(p) = i_0(a)$ and $g_2(p) = b$. Note that $i_0$ is injective so $u_1(p) = a$. Finally, $(u_1 g_2)(p) = (\pi')$. This shows the reverse inclusion and completes the proof of the lemma.

The next proposition describes an isomorphism between induction and coinduction for a particular type of modules.

**Proposition 5.5.** Suppose $\text{gl.dim} \, C = 2$ and $M = \tau \Omega^{-1} \Omega^{-1} N$ for some $N \in \text{mod} \, C$. Then the induction of $M$ is isomorphic to the coinduction of $M \otimes E$ and there is a commutative diagram with exact rows

\[
\begin{array}{ccc}
0 & \rightarrow & M \otimes E & \xrightarrow{1 \otimes \iota} & M \otimes B & \xrightarrow{1 \otimes \pi} & M \otimes C & \xrightarrow{0} \\
\downarrow{\phi} & & \downarrow{\theta} & & \downarrow{\psi} & & \\
0 & \rightarrow & \text{Hom}_C(C, M \otimes E) & \xrightarrow{\pi} & \text{Hom}_C(B, M \otimes E) & \xrightarrow{i^*} & \text{Hom}_C(E, M \otimes E) & \xrightarrow{0} \\
\end{array}
\]

where $\phi, \theta, \text{ and } \psi$ are isomorphisms of $B$-modules.

**Proof.** First observe that the top row is a short exact sequence by Proposition 3.6(a), and the bottom row is a short exact sequence by Propositions 3.6(b) and 3.3(b). The maps $i$ and $\pi$ are as in sequence (1). Next we explicitly describe the rest of the maps that appear in the diagram above.
Let us begin with the definition of $\psi$. First, consider
\[
M \cong \tau \Omega \tau^{-1} \Omega^{-1} N \\
\cong D(E \otimes D\tau^{-1} \Omega^{-1} N) \quad \text{by Proposition 4.1(d)} \\
\cong \text{Hom}_C(E, \tau^{-1} \Omega^{-1} N) \quad \text{by Lemma 3.2} \\
\cong \text{Hom}_C(E, N \otimes E) \quad \text{by Proposition 4.1(c)}.
\]
Then Proposition 5.2 implies that
\[
M \otimes E \cong N \otimes E
\]
and in turn
\[
\text{Hom}_C(E, M \otimes E) \cong \text{Hom}_C(E, N \otimes E) \cong M.
\]
Now, there exists a unique $C$-module homomorphism $\psi$ such that
\[
\psi : M \otimes C \to \text{Hom}_C(E, M \otimes E)
\]
\[
m \otimes c \mapsto (e \mapsto mc \otimes e).
\]
Next, we want to show that $\psi$ is injective. Since $M \otimes C \cong M$, it suffices to show that $\psi(m \otimes 1) = 0$ if and only if $m = 0$. Now suppose that $\psi(m \otimes 1) = 0$ for some $m \otimes 1 \in M \otimes C$, which means $m \otimes e = 0$, for all $e \in E$, and we need to show that $m = 0$. For this we use the universal property of the tensor product. Consider the diagram
\[
\begin{array}{ccc}
M \times E & \longrightarrow & M \otimes_C E \\
\downarrow & & \downarrow \Psi \\
N \otimes E & \longleftarrow & \text{Hom}_C(B, M \otimes E)
\end{array}
\]
where $\overline{\psi}(m, e) = m(e)$. Recall that we can think of $M$ as $\text{Hom}_C(E, N \otimes E)$, so here by $m(e)$ we understand a map $m$ evaluated at an element $e \in E$. One can check that $\overline{\psi}$ is a $C$-balanced map, and the universal property of the tensor product implies that there exists a unique $C$-module homomorphism $\Psi$ such that $\Psi(m \otimes e) = m(e)$. Now suppose $m \otimes e = 0$ for all $e \in E$. Then $\Psi(m \otimes e) = m(e) = 0$ for all $e \in E$, which means that $m$ is the zero map, thus $m = 0$. This shows that $\psi$ is an injective $C$-module homomorphism, but since $M \cong \text{Hom}_C(E, M \otimes E)$ are finite dimensional, this shows that $\psi$ is a $C$-module isomorphism. Because every $C$-module is also a $B$-module by defining the action of $E$ to be trivial, then $\psi$ is also a $B$-module isomorphism.

Now we define $\theta$, and again we use the universal property of the tensor product. Consider the diagram
\[
\begin{array}{ccc}
M \times B & \longrightarrow & M \otimes_C B \\
\downarrow & & \downarrow \theta \\
\text{Hom}_C(B, M \otimes E) & \longleftarrow &
\end{array}
\]
where
\[
\varphi : (m, (c, e)) \longmapsto ((c', e') \mapsto m \otimes (ce' + ec')).
\]
Again one can easily check that this map is $C$-balanced, so the universal property of the tensor product implies that there exists a unique $C$-module homomorphism $\theta$ such that
\[
\theta(m \otimes (c, e)) = ((c', e') \mapsto m \otimes (ce' + ec')).
\]
Now we want to show that \( \theta \) is a \( B \)-module homomorphism. Observe that for all \((\tilde{c}, \tilde{e}) \in B\) and \(m \otimes (c, e) \in M \otimes B\) we have
\[
\theta(m \otimes (c, e)) \cdot (\tilde{c}, \tilde{e}) = ((c', e') \mapsto m \otimes (ce' + ec')) \cdot (\tilde{c}, \tilde{e})
\]
\[
= ((c', e') \mapsto m \otimes (\tilde{c}ce' + \tilde{e}c') + ec'').
\]
On the other hand
\[
\theta(m \otimes (c, e) \cdot (\tilde{c}, \tilde{e})) = \theta(m \otimes (\tilde{c}c, \tilde{e} + e\tilde{c}))
\]
\[
= ((c', e') \mapsto m \otimes (\tilde{c}ce' + (c\tilde{e} + e\tilde{c})c')),
\]
and the two expressions are the same. This shows that \( \theta \) is a \( B \)-module homomorphism.

Finally, we define the morphism \( \phi \). Let
\[
\phi : M \otimes E \to \text{Hom}_C(C, M \otimes E)
\]
\[
\phi : m \otimes e \mapsto (c \mapsto (m \otimes e) \cdot c)
\]
which is a standard isomorphism of \( C \)-modules. By the same reasoning as above it is also an isomorphism of \( B \)-modules. Thus we defined all morphisms appearing in the proposition, so it remains to show that the corresponding diagram is commutative. Let \( m \otimes e \in M \otimes E \), then consider
\[
\pi^* \phi(m \otimes e) = \pi^*(c \mapsto (m \otimes e) \cdot c)
\]
\[
= (c \mapsto (m \otimes e) \cdot c) \circ \pi
\]
\[
= ((c', e') \mapsto m \otimes e \cdot \pi(c', e'))
\]
\[
= ((c', e') \mapsto m \otimes e \cdot (c', 0))
\]
\[
= ((c', e') \mapsto m \otimes ec').
\]
On the other hand
\[
\theta(1 \otimes i)(m \otimes e) = \theta(m \otimes i(e))
\]
\[
= \theta(m \otimes (0, e))
\]
\[
= ((c', e') \mapsto m \otimes ec').
\]
This shows that the first square commutes. Now let \( m \otimes (c, e) \in M \otimes B \) and consider
\[
i^* \theta(m \otimes (c, e)) = i^*((c', e') \mapsto m \otimes (ce' + ec'))
\]
\[
= (e' \mapsto m \otimes ce').
\]
Also,
\[
\psi(1 \otimes \pi)(m \otimes (c, e)) = \psi(m \otimes c)
\]
\[
= (e' \mapsto mc \otimes e')
\]
\[
= (e' \mapsto m \otimes ce').
\]
This shows that the second square commutes.

Next the Five Lemma implies that \( \theta \) is a \( B \)-module isomorphism. This completes the proof of the proposition. \( \square \)

The following corollary is a reformulation of Proposition 5.5 and will be used in the proof of Theorem 5.7.
Corollary 5.6. Suppose $\text{gl.dim } C = 2$ and $M = \tau \Omega^{-1} \Omega^{-1} N$ for some $N \in \text{mod } C$. Then there is a commutative diagram with exact rows

$$
\begin{array}{ccccccccc}
0 & \rightarrow & N \otimes E & \delta_0 & M \otimes B & \delta_1 & M & \rightarrow & 0 \\
& & \downarrow \phi' & & \downarrow \phi & & \downarrow \psi & & \\
0 & \rightarrow & N \otimes E & \beta_0 & \text{Hom}_C(B, N \otimes E) & \beta_1 & M & \rightarrow & 0
\end{array}
$$

where $\phi', \theta'$, and $\psi'$ are isomorphisms of $B$-modules.

Proof. First observe that the top row of this diagram is equivalent to the top row of the diagram in Proposition 5.5. Also, in the proof of this proposition we showed that $N \otimes E \cong M \otimes E$ and $M \cong \text{Hom}_C(E, M \otimes E)$. This implies that the bottom rows of the two diagrams are also equivalent. Thus, we conclude that there exist $\phi', \theta'$, and $\psi'$ that make the diagram above commute. \qed

The following theorem is the main theorem of the section. It explicitly describes an injective resolution of length at most one for each projective module in a cluster-tilted algebra.

Theorem 5.7. Let $C$ be a tilted algebra, $B$ the corresponding cluster-tilted algebra, $P_C$ a projective $C$-module and $P_B$ the corresponding projective $B$-module. Let

$$
0 \rightarrow P_C \rightarrow I^0_C \rightarrow I^1_C \quad \text{and} \quad 0 \rightarrow P_C \otimes E \rightarrow I^0_C \rightarrow I^1_C
$$

be minimal injective presentations in $\text{mod } C$, and let $\tilde{I}_C$ be the injective $C$-module $\tilde{I}_C = \nu \nu^{-1} \Omega^{-1} P_C$. Then

$$
0 \rightarrow P_B \rightarrow I^0_B \oplus \tilde{I}^0_B \rightarrow \tilde{I}_B \oplus \tilde{I}^1_B \rightarrow 0
$$

is an injective resolution of $P_B$ in $\text{mod } B$.

Remark. If the injective dimension of $P_C$ is at most one, then $P_C \otimes E = 0$, by Proposition 4.2(a), and $\tilde{I}_C = \nu \nu^{-1} \Omega^{-1} P_C = \nu \nu^{-1} I^1_C = I^1_C$. Thus in this case the injective resolution is

$$
0 \rightarrow P_B \rightarrow I^0_B \rightarrow I^1_B \rightarrow 0.
$$

Moreover, this resolution is minimal.

Proof. If $\text{id}_C P_C \leq 1$, then consider a minimal injective resolution of $P_C$ in $\text{mod } C$

$$
0 \rightarrow P_C \rightarrow I^0_C \rightarrow I^1_C \rightarrow 0
$$

of length at most one. We apply the coinduction functor $\text{Hom}_C(B, -)$ to the injective resolution of $P_C$ and obtain

$$
0 \rightarrow P_C \rightarrow I^0_B \rightarrow I^1_B \rightarrow \text{Ext}^1_C(B, P_C) .
$$

Indeed the injectives in $\text{mod } C$ will map to the corresponding injectives in $\text{mod } B$, and $P_C$ will not change, by Proposition 4.2(b). Also, there is a $C$-module isomorphism $\text{Ext}^1_C(B, P_C) \cong \text{Ext}^1_C(C \oplus E, P_C) \cong \text{Ext}^1_C(E, P_C)$ which is zero, by Lemma 4.7(a). Finally, observe that since $\text{id}_C P_C \leq 1$ then $P_B \cong P_C \otimes B \cong P_C$ by Propositions 3.4(a) and 4.2(a). It also shows that $P_C \otimes E = 0$, which means that both injectives $I^0_B$ and $I^1_B$ are zero. Finally, the remark above implies that $\tilde{I}_B = I^1_B$. Thus, if $\text{id}_C P_C \leq 1$ we obtain the injective resolution of $P_B$ as in the statement of the theorem.
If \( \text{id}_C P_C = 2 \). We start by defining the morphisms in the injective resolution. In order to do so, consider the following commutative diagram

\[
\begin{array}{c}
0 & \rightarrow & P_C \otimes E & \stackrel{\beta_0}{\rightarrow} & \text{Hom}_C(B, P_C \otimes E) & \stackrel{\beta_1}{\rightarrow} & \tau \Omega \tau^{-1} \Omega^{-1} P_C & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & \bar{I}_C^0 & \stackrel{v_0}{\rightarrow} & \bar{I}_B^0 & \stackrel{v_1}{\rightarrow} & \tau \Omega \bar{I}_C^0 & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & \bar{I}_C^1 & \stackrel{l_2}{\rightarrow} & \bar{I}_B^1 & \stackrel{\kappa_2}{\rightarrow} & \tau \Omega \bar{I}_C^1 & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & & 0 & & 0 & & 0 & & 
\end{array}
\]

where every row and column is exact. To construct this diagram, we begin with the injective resolution in \( \mod C \) of \( P_C \otimes E \) as in the statement of the theorem. Note that, by Lemma 4.5(a), \( \text{id}_C P_C \otimes E \leq 1 \). This sequence appears in the left most column of the diagram above. Then we apply the coinduction functor \( \text{Hom}_C(B, -) \) to this sequence and recall that \( \text{Ext}^1_C(E, P_C \otimes E) = 0 \), by Corollary 4.8. This gives us the short exact sequence to the right of the one we started with, which is the middle column of the diagram. We also obtain inclusions \( \beta_0, v_0, l_2 \) from the given \( C \)-modules to the corresponding coinduced \( B \)-modules and projections \( \beta_1, v_1, k_2 \) to the corresponding cokernels as in Proposition 3.6(b). By the same proposition, \( \text{cok} \beta_0 = D(E \otimes D(P_C \otimes E)) \cong \tau \Omega \tau^{-1} \Omega^{-1} P_C \), where the last identity follows from Proposition 4.1. Similarly, \( \text{cok} v_0 \cong \tau \Omega \bar{I}_C^0 \), and \( \text{cok} l_2 \cong \tau \Omega \bar{I}_C^1 \). Thus we obtain the commutative diagram \( 6 \).

Now we construct the commutative diagram \( 7 \) with exact rows, which appears below. We obtain the bottom two rows from Corollary 5.6 by letting \( N = P_C \). Next, we draw a commutative diagram \( 5 \) in the top right corner, where the maps \( g_1 \) and \( g_2 \) are as in Lemma 5.4. We complete the top row by \( P_C \otimes E \), the kernel of \( u_1 \), as in Proposition 3.6(a). Finally, by the universal property of ker \( \delta_1 \) there exists a morphism \( \epsilon_0 \) that completes the diagram and makes the upper left square commute. Note that the bottom row of diagram \( 7 \) is the same as the top row of diagram \( 6 \).

\[
\begin{array}{c}
0 & \rightarrow & P_C \otimes E & \stackrel{u_0}{\rightarrow} & P_B & \stackrel{u_1}{\rightarrow} & P_C & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & P_C \otimes E & \stackrel{\delta_0}{\rightarrow} & \tau \Omega \tau^{-1} \Omega^{-1} P_C \otimes B & \stackrel{\delta_1}{\rightarrow} & \tau \Omega \tau^{-1} \Omega^{-1} P_C & \rightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \rightarrow & P_C \otimes E & \stackrel{\beta_0}{\rightarrow} & \text{Hom}_C(B, P_C \otimes E) & \stackrel{\beta_1}{\rightarrow} & \tau \Omega \tau^{-1} \Omega^{-1} P_C & \rightarrow & 0.
\end{array}
\]

Next we want to show that \( \epsilon_0 \) is an isomorphism. Observe that, since \( P_C \otimes E \) is finite dimensional, it suffices to show that \( \epsilon_0 \) is injective. Suppose \( \epsilon_0(a) = 0 \), for some \( a \in P_C \otimes E \). Let \( u_0(a) = b \). Because \( u_0 \) is injective, it is enough to show that \( b = 0 \). By commutativity
$g_2(b) = 0$, but looking at the top row of Lemma \ref{lemma5.4} we conclude that either $b = 0$ or $u_1(b) \neq 0$. In the first case we are done, so suppose $u_1(b) \neq 0$. Then $u_1(b) = u_1u_0(a) \neq 0$, which is a contradiction since the top row of the diagram \ref{diagram7} is exact. This shows that $a = b = 0$ and that $c_0$ is an isomorphism.

Now we show that the following sequence as in the statement of the theorem is exact

$$0 \rightarrow P_B \xrightarrow{(j_0i_0u_1)_{\gamma_0\theta'g_2}} \bar{I}_B^0 \oplus \bar{I}_B^0 \xrightarrow{\begin{pmatrix} \alpha & -l_1\gamma v_1 \\
\pi & \pi_0 \end{pmatrix}} \bar{I}_B \oplus \bar{I}_B \rightarrow 0$$

where the maps are $v_1, \pi, \gamma_0$ are given in diagram \ref{diagram6}, the maps $\theta', u_1, g_2$ in diagram \ref{diagram7}, the maps $i_0, j_0, \alpha, l_1$ in Lemma \ref{lemma5.3} and $\gamma$ in diagram \ref{diagram8} below.

\begin{equation}
(8)
\begin{tikzcd}
\tau\Omega \tau^{-1}\Omega^{-1} P_C \arrow{r}{\pi_0} \arrow{d}[swap]{\gamma_1\psi'} & \bar{I}_C \arrow{d}{\gamma} \\
\tau\Omega \bar{I}_C^0 \arrow{ur}[swap]{\gamma_1\tilde{\psi}}
\end{tikzcd}
\end{equation}

Here $\pi_0$ is the map of Lemma \ref{lemma5.1}. Observe that $\gamma$ exists because $\bar{I}_C$ is injective and $\gamma_1\psi'$ is an injective map. Moreover, the map $\gamma$ makes the diagram commute, that is $\gamma_1\psi' = \pi_0$.

First we show that the sequence we defined above is exact at $P_B$. Suppose $(j_0i_0u_1)_{\gamma_0\theta'g_2}(p) = 0$ for some $p \in P_B$. So on the one hand $j_0i_0u_1(p) = 0$, but $j_0$ and $i_0$ are injective, which means $u_1(p) = 0$. By diagram \ref{diagram7} there exists $b \in \mathcal{P}_C \otimes \mathcal{E}$ such that $u_0(b) = p$. On the other hand, $\gamma_0\theta'g_2u_0(b) = 0$, but by commutativity in diagram \ref{diagram7} this is equivalent to $\gamma_0\beta_0\theta'c_0(b) = 0$. Because, all of these maps are injective it follows that $b = 0$, which implies $p = 0$. This shows that $(j_0i_0u_1)_{\gamma_0\theta'g_2}$ is an injective map.

Next we show that $\text{im}(j_0i_0u_1)_{\gamma_0\theta'g_2} = \ker(\begin{pmatrix} \alpha & -l_1\gamma v_1 \\
\pi & \pi_0 \end{pmatrix})$, meaning that the sequence is exact at $\bar{I}_B^0 \oplus \bar{I}_B^0$. To show the forward inclusion consider $(\begin{pmatrix} \alpha & -l_1\gamma v_1 \\
\pi & \pi_0 \end{pmatrix})(j_0i_0u_1)_{\gamma_0\theta'g_2} = (\begin{pmatrix} \alpha & -l_1\gamma v_1 \\
\pi & \pi_0 \end{pmatrix})\pi_0$. Observe that $\pi_0 = 0$ by diagram \ref{diagram6}, which means that the bottom entry is zero. The top entry is also zero, because

$$\alpha j_0i_0u_1 - l_1\gamma v_1\gamma_0\theta'g_2 = l_1(\pi_0g_1u_1 - \gamma v_1\gamma_0\theta'g_2)$$

by first row in Lemma \ref{lemma5.3}

$$= l_1(\gamma_1\psi'g_1u_1 - \gamma v_1\gamma_0\theta'g_2)$$

by diagram \ref{diagram8}

$$= l_1(\gamma_1\psi'g_1u_1 - \gamma v_1\gamma_0\theta'g_2)$$

by diagram \ref{diagram7},

which is zero by commutativity of diagram \ref{diagram6}. To show the reverse inclusion suppose $(\begin{pmatrix} \alpha & -l_1\gamma v_1 \\
\pi & \pi_0 \end{pmatrix})(b) = (\begin{pmatrix} 0 \\
0 \end{pmatrix})$ for some $a \in I_B^0, b \in \bar{I}_B^0$. Since $\alpha(a) - l_1\gamma v_1(b) = 0$ and the bottom row in the diagram of Lemma \ref{lemma5.3} is exact, there exists $c \in I_B^0$ such that $j_0(c) = a$ and $g_0(c) = \gamma v_1(b)$. Also, we have $\pi(b) = 0$, so by diagram \ref{diagram6} there exists $d \in \text{Hom}_C(B, \mathcal{P}_C \otimes \mathcal{E})$, such that $\gamma_0(d) = b$. Since $\theta'$ is an isomorphism we can find $e \in \tau\Omega \tau^{-1}\Omega^{-1} P_C \otimes B$ such that $\theta'(e) = d$. Now we have

$$g_0(c) = \gamma v_1\gamma_0\theta'(e)$$

by diagram \ref{diagram6}

$$= \gamma_1\beta_1\theta'(e)$$

by diagram \ref{diagram7}

$$= \gamma_1\psi'\delta_1(e)$$

by diagram \ref{diagram8}.
Equivalently we can write $g_0(c) - \pi_0\delta_1(e) = 0$, and since the bottom row in the diagram of Lemma 5.4 is exact, there exists $p \in P_B$ such that $i_0 u_4(p) = c$ and $g_2(p) = e$. Now consider $(j_0 \gamma_0 u_1)(p) = (j_0(c)) = (a, b)$. This shows exactness at $I_B^0 \oplus I_B^0$.

It remains to show that $(\alpha - t_1 \gamma_0 v_1)$ is surjective. By definition, $\pi$ is surjective, thus it suffices to show that $(\alpha - t_1 \gamma_0 v_1)$ is surjective. That is, given $a \in \widetilde{I}_B$ find $c \in I_B^0$, $d \in I_B^0$ such that $\alpha(c) - l_1 \gamma_0 v_1(d) = a$. By Lemma 5.3, there exist $c' \in I_B^0$ and $e \in \widetilde{I}_C$ such that $\alpha(c') - l_1(e) = a$. Then by Lemma 5.4 there exist $m \in I_B^0$ and $n \in \tau \Omega^{-1} \Omega^{-1} P_C \otimes B$ such that $g_0(m) - \pi_0 \delta_1(n) = e$. Finally, let $d = \gamma_0 \theta'(n) \in \widetilde{I}_B$ and $c = j_0(m) + c' \in I_B^0$ and observe that

$$
\alpha(j_0(m) + c') - l_1 \gamma_0 v_1(\gamma_0 \theta'(n)) = l_1 g_0(m) + \alpha(c') - l_1 \gamma_0 \gamma_0 \theta'(n)
= \alpha(c') + l_1 g_0(m) - \gamma_0 \gamma_0 \theta'(n)
= \alpha(c') - l_1 g_0(m) - \gamma_0 \gamma_0 \theta'(n)
= \alpha(c') - l_1 g_0(m) - \pi_0 \delta_1(n)
= a.
$$

This shows surjectivity and finishes the proof of the theorem.

**Remark.** The theorem above can be dualized. That is, in a similar manner one can construct a projective resolution of an injective $\widetilde{B}$-module of length at most one.

We obtain therefore a new proof of the following result which was first proved by Keller and Reiten using cluster categories [KR].

**Corollary 5.8.** If $C$ is a tilted algebra and $B$ is the corresponding cluster-tilted algebra, then $B$ is 1-Gorenstein.

**Example 5.9.** Let $C$ be the tilted algebra given by the following quiver with relations.

```
1
|   |
| → |
|   |
3 → 4 ← 5
```

The corresponding cluster-tilted algebra $B$ is given by the quiver with relations below.

```
1
|   |
| → |
|   |
3 → 4 ← 5
```

We want to construct the injective resolution of $P_B(1) = \frac{1}{2} \frac{3}{4}$ as described in the theorem above. Observe that $P_B(1) = P_C(1)$, hence $P_C(1) \otimes E = 0$ and $\text{id}_C P_C(1) \leq 1$. In this case we only need to consider the minimal injective resolution of $P_C(1)$ given below.

```
0 → P_C(1) → I_C(2) \oplus I_C(4) → I_C(3) → 0
```
Now according to the remark following the statement of Theorem 5.7 we obtain the minimal injective resolution of $P_B(1)$ as shown below.

$$
\begin{array}{c}
0 \rightarrow P_B(1) \rightarrow I_B(2) \oplus I_B(4) \rightarrow I_B(3) \rightarrow 0
\end{array}
$$

Note that here $I_B(2) \neq I_C(2)$ and $I_B(3) \neq I_C(3)$.

**Example 5.10.** Let $C$ be the tilted algebra given by the following quiver with relations.

\[
\begin{array}{cccccc}
5 & 2 & \uparrow \\
\downarrow & \alpha & \delta \\
1 & \delta & \gamma & 4 \\
\beta & \gamma & \downarrow & \leftarrow & \leftarrow & \leftarrow \\
\downarrow & \downarrow & \gamma & \beta & \sigma & 3 \\
\end{array}
\]

\[
\begin{array}{c}
\delta \alpha = 0 \\
\gamma \beta = 0.
\end{array}
\]

The corresponding cluster-tilted algebra $B$ is of type $\tilde{A}_{(3,2)}$ and it is given by the quiver with relations below.

\[
\begin{array}{cccccc}
5 & 2 & \uparrow \\
\downarrow & \alpha & \delta & \epsilon \\
1 & \delta & \gamma & 4 \\
\beta & \gamma & \downarrow & \leftarrow & \leftarrow & \leftarrow \\
\downarrow & \downarrow & \gamma & \beta & \sigma & 3 \\
\end{array}
\]

\[
\begin{array}{c}
\delta \alpha = \alpha \epsilon = \epsilon \delta = 0 \\
\gamma \beta = \beta \sigma = \sigma \gamma = 0.
\end{array}
\]

We want to construct the injective resolution of $P_B(2) = \frac{2}{5}$, the projective $B$-module at vertex 2, as in Theorem 5.7. First, we find minimal injective presentations of $P_C(2) = \frac{2}{5}$ and $P_C(2) \otimes E = \frac{4}{5}$ in mod $C$, which are given below.

$$
\begin{array}{c}
0 \rightarrow P_C(2) \rightarrow I_C(5) \rightarrow I_C(1) \phantom{a} 0 \rightarrow P_C(2) \otimes E \rightarrow I_C(5) \rightarrow 0
\end{array}
$$

We write out the explicit representations involved in the sequences above.

$$
\begin{array}{cccccc}
0 \rightarrow \frac{2}{5} \rightarrow \frac{4}{5} \rightarrow \frac{4}{1} \rightarrow 0 \\
0 \rightarrow \frac{4}{5} \rightarrow \frac{4}{5} \rightarrow 0
\end{array}
$$

Here $I_C(i)$ denotes the injective $C$-module at vertex $i$, while $I_B(i)$ will denote the corresponding injective $B$-module. Next, we calculate $\nu \nu^{-1} \Omega^{-1} P_C(2)$. Observe that $\Omega^{-1} P_C(2)$ is the module with dimension vector $(1, 0, 0, 1, 0)$ such that $\gamma = 1$ and $\delta = 0$. Then $\nu^{-1} \Omega^{-1} P_C(2) = \text{Hom}_C(DC, \Omega^{-1} P_C(2))$, and the only injectives that have a nonzero morphism into $\Omega^{-1} P_C(2)$ are $I_C(2)$ and $I_C(5)$. Hence, $\nu^{-1} \Omega^{-1} P_C(2) = P_C(2)$, so $\nu \nu^{-1} \Omega^{-1} P_C(2) = I_C(2)$. Then according to Theorem 5.7 we construct the injective resolution of $P_B(2)$

$$
\begin{array}{c}
0 \rightarrow P_B(2) \rightarrow I_B(5) \oplus I_B(5) \rightarrow I_B(2) \oplus 0 \rightarrow 0
\end{array}
$$
or equivalently substituting the representations we have

\[
\begin{array}{ccccccccc}
0 & \rightarrow & \frac{2}{5} & \rightarrow & \frac{2}{5} & \oplus & \frac{1}{5} & \rightarrow & \frac{2}{5} & \rightarrow & 0.
\end{array}
\]

6. Relation to Cluster Categories

In this section we study the relationship between induction and coinduction functors and the cluster category. Here, we assume that \(A\) is a hereditary algebra and \(T \in \text{mod} \ A\) is a basic tilting module. Let \(C = \text{End}_A T\) be the corresponding tilted algebra, and \(B = C \ltimes E\) be the associated cluster-tilted algebra. Finally, let \(\mathcal{C}_A\) denote the cluster category of \(A\). We know that \(\text{mod} \ A\) naturally embeds in \(\mathcal{C}_A\), which in turn maps surjectively onto \(\text{mod} \ B\) via the functor \(\text{Hom}_{\mathcal{C}_A}(T, -)\). Recall that the induction functor \(- \otimes C B\) and the coinduction functor \(D(B \otimes_C D -)\) both map \(\text{mod} \ C\) to \(\text{mod} \ B\), while the module categories of \(A\) and \(C\) are closely related via the Tilting Theorem 2.1. Now, we want to study how the induction and the coinduction functors fit into this larger picture.

![Diagram](image)

The following theorem describes the relationship between the induction functor and the cluster category.

**Theorem 6.1.** Let \(A\) be a hereditary algebra and \(T \in \text{mod} \ A\) a basic tilting module. Let \(\mathcal{C}_A\) be the cluster category of \(A\), \(C = \text{End}_A T\) be the corresponding tilted algebra, and \(B = C \ltimes E\) the corresponding cluster-tilted algebra. Recall the definitions of \(\mathcal{T}(T)\) and \(\mathcal{Y}(T)\), the associated torsion class of \(\text{mod} \ A\) and the torsion free class of \(\text{mod} \ C\) below.

\[
\mathcal{T}(T) = \{ M \in \text{mod} \ A \mid \text{Ext}_A^1(T, M) = 0 \} \quad \mathcal{Y}(T) = \{ N \in \text{mod} \ C \mid \text{Tor}_C^1(N, T) = 0 \}
\]

Then the following diagram commutes.

\[
\begin{array}{ccc}
\mathcal{T}(T) & \xrightarrow{\text{Hom}_A(T, -)} & \mathcal{Y}(T) \\
\downarrow & & \downarrow \\
\mathcal{C}_A & \xrightarrow{\text{Hom}_{\mathcal{C}_A}(T, -)} & \text{mod} B
\end{array}
\]

That is, \(\text{Hom}_A(T, M) \otimes_C B \cong \text{Hom}_{\mathcal{C}_A}(T, M)\) for every \(M \in \mathcal{T}(T)\).

**Proof.** Let \(M\) be an indecomposable module belonging to \(\mathcal{T}(T)\). If \(M \in \text{add} T\), then \(\text{Hom}_A(T, M)\) is a projective \(C\)-module, and \(\text{Hom}_A(T, M) \otimes_C B\) is the corresponding projective \(B\)-module. On the other hand, \(\text{Hom}_{\mathcal{C}_A}(T, M)\) is also the same projective \(B\)-module. Hence, in this case the theorem above holds. If \(M \not\in \text{add} T\), then Proposition 2.3(d) implies that the projective dimension of \(\text{Hom}_A(T, M) \in \mathcal{Y}(T)\) is one. Let

\[
0 \rightarrow P_C^0 \xrightarrow{f} P_C^0 \rightarrow \text{Hom}_A(T, M) \rightarrow 0
\]
be its minimal projective resolution in mod $C$. By Theorem 2.1(a), there exist $T^0, T^1 \in \text{add } T$, and $g \in \text{Hom}_A(T^1, T^0)$ such that

$$f = \text{Hom}_A(T, g), \quad P^1_C = \text{Hom}_A(T, T^1), \quad P^0_C = \text{Hom}_A(T, T^0).$$

Moreover, since $M \in \mathcal{T}(T)$, we have that $M = \text{coker } g$. Applying $- \otimes_C T$ to the projective resolution (9) and using Theorem 2.1(a), we obtain an exact sequence

$$\text{Tor}_1^C(\text{Hom}_A(T, M), T) \xrightarrow{g} T^1 \xrightarrow{g} T^0 \xrightarrow{g} M \xrightarrow{g} 0.$$

Furthermore, $\text{Tor}_1^C(\text{Hom}_A(T, M), T) = 0$ by Tilting Theorem 2.1, which means that the sequence above is a short exact sequence in mod $A$. Observe that $g$ is also a morphism in the cluster category, and the short exact sequence above corresponds to a triangle

$$T^1 \xrightarrow{g} T^0 \xrightarrow{g} M \xrightarrow{g} T^1[1]$$

in $C_A$. Applying $\text{Hom}_{C_A}(T, -)$ to this triangle yields an exact sequence in mod $B$

$$\text{Hom}_{C_A}(T, T^1) \xrightarrow{g} \text{Hom}_{C_A}(T, T^0) \xrightarrow{g} \text{Hom}_{C_A}(T, M) \xrightarrow{g} 0.$$

Note that there is zero on the right of the sequence as $\text{Hom}_{C_A}(T, T^1[1]) = 0$, because $T$ is a tilting object in $C_A$. Also, $\text{Hom}_{C_A}(T, T^1) = P^1_B$ and $\text{Hom}_{C_A}(T, T^0) = P^0_B$, thus

$$\text{Hom}_{C_A}(T, M) = \text{coker } \text{Hom}_{C_A}(T, g) : P^1_B \rightarrow P^0_B.$$

On the other hand, applying the induction functor $- \otimes_C B$ to the sequence (9) we obtain

$$P^1_B \xrightarrow{f \otimes 1} P^0_B \xrightarrow{g} \text{Hom}_A(T, M) \otimes_C B \xrightarrow{g} 0.$$

Hence, we see that

$$\text{Hom}_A(T, M) \otimes_C B = \text{coker } \text{Hom}_A(T, g) \otimes 1 : P^1_B \rightarrow P^0_B.$$

But since top $P^1_B = \text{top } P^1_C$, we have

$$\text{Hom}_{C_A}(T, g)(\text{top } P^1_B) = \text{Hom}_A(T, g)(\text{top } P^1_C) = \text{Hom}_A(T, g) \otimes 1 (\text{top } P^1_B).$$

Because $P^1_B$ is projective both maps $\text{Hom}_{C_A}(T, g)$ and $\text{Hom}_A(T, g) \otimes 1$ are determined by their restrictions to top $P^1_B$. Therefore, we construct a commutative diagram

$$\begin{array}{ccc}
P^1_B & \xrightarrow{\text{Hom}_{C_A}(T, g)} & P^0_B \\
\downarrow & & \downarrow \cong \\
P^1_B & \xrightarrow{\text{Hom}_A(T, g) \otimes 1} & P^0_B \\
\end{array} \xrightarrow{h} \begin{array}{ccc}
\text{Hom}_{C_A}(T, M) & \rightarrow & \text{Hom}_A(T, M) \\
\rightarrow & & \rightarrow 0 \\
\end{array} \xrightarrow{h} \begin{array}{ccc}
\text{Hom}_A(T, M) \otimes_C B & \rightarrow & 0 \\
\rightarrow & & \rightarrow 0 \\
\end{array}$$

where $h$ is an isomorphism by the Five Lemma. This shows that for every $M \in \mathcal{T}(T)$ we have $\text{Hom}_{C_A}(T, M) \cong \text{Hom}_A(T, M) \otimes_C B$, and finishes the proof of the theorem. □

This result shows that the induction functor can be reformulated in terms of other well-studied functors. In particular consider the following corollary.
Corollary 6.2. Let $A$ be a hereditary algebra and $T \in \mod A$ a basic tilting module. Let $\mathcal{C}_A$ be the cluster category of $A$, $C = \text{End}_A T$ be the corresponding tilted algebra, and $B = C \rtimes E$ the corresponding cluster-tilted algebra. Then

$$M \otimes_C B \cong \begin{cases} \text{Hom}_{\mathcal{C}_A}(T, M \otimes_C T) & \text{if } M \in \mathcal{X}(T) \\ M & \text{if } M \in \mathcal{Y}(T) \end{cases}$$

for every $M \in \text{ind} C$.

Proof. First, note that every $M \in \text{ind} C$ belongs to either $\mathcal{X}(T)$ or $\mathcal{Y}(T)$ by Proposition 2.3(e). If $M \in \mathcal{X}(T)$, Proposition 2.3(c) implies that $\text{id}_C M \leq 1$, and then Proposition 4.2(a) yields $M \otimes_C B \cong M$. If $M \in \mathcal{Y}(T)$, then Theorem 2.1(a) implies that $M \cong \text{Hom}_A (T, N)$ for $N = M \otimes_C T \in \mathcal{T}(T)$. Hence $M \otimes_C B \cong \text{Hom}_{\mathcal{C}_A}(T, N)$, by Theorem 6.1.

Similarly, there is a dual statement that provides an alternative description of the coinduction functor.

Theorem 6.3. Let $A$ be a hereditary algebra and $T \in \mod A$ a basic tilting module. Let $\mathcal{C}_A$ be the cluster category of $A$, $C = \text{End}_A T$ be the corresponding tilted algebra, and $B = C \rtimes E$ the corresponding cluster-tilted algebra. Recall the definitions of $\mathcal{F}(T)$ and $\mathcal{X}(T)$, the associated torsion free class of $\mod A$ and the torsion class of $\mod C$ below.

$$\mathcal{F}(T) = \{ M \in \mod A \mid \text{Hom}_A (T, M) = 0 \} \quad \mathcal{X}(T) = \{ N \in \mod C \mid N \otimes_C T = 0 \}$$

Then the following diagram commutes.

$$\begin{array}{ccc}
\mathcal{F}(T) & \xrightarrow{\text{Ext}_A^1(T, -)} & \mathcal{X}(T) \\
\downarrow \quad & & \downarrow \\
\mathcal{C}_A & \xrightarrow{\text{Ext}_A^1(T, -)} & \mod B
\end{array}$$

That is, $D (B \otimes_C D \text{Ext}_A^1(T, M)) \cong \text{Ext}_A^1(M, T)$, for every $M \in \mathcal{F}(T)$.

Proof. Let $M$ be an indecomposable module belonging to $\mathcal{F}(T)$. Consider $\text{Ext}_A^1(T, M)$, which belongs to $\mathcal{X}(T)$ by Theorem 2.1(b). If $\text{Ext}_A^1(T, M) = I_B^i$ is an injective $C$-module, then $D (B \otimes_C D I_B^i) \cong I_B^i$ is the corresponding injective in $\mod B$. On the other hand, by Proposition 2.4 we have $M \cong \tau T^i$ for some $T^i \in \text{add} T$. Therefore, by Serre Duality

$$\text{Ext}_A^1(T, \tau T^i) \cong D \text{Hom}_{\mathcal{C}_A}(T^i, T) \cong I_B^i.$$

This shows that the theorem holds if $\text{Ext}_A^1(T, M)$ is injective.

If $\text{Ext}_A^1(T, M) \in \mathcal{X}(T)$ is not injective then according to Proposition 2.3(c) it has injective dimension one. Consider a minimal injective resolution of this module in $\mod C$ below.

$$0 \rightarrow \text{Ext}_A^1(T, M) \rightarrow I_C^0 \xrightarrow{f} I_C^1 \rightarrow 0$$

Because $I_C^0, I_C^1$ are successors of $\text{Ext}_A^1(T, M)$, Proposition 2.3(f) implies that these injectives belong to $\mathcal{X}(T)$. By Proposition 2.4 and Theorem 2.1(b), there exist $T^i, T^0 \in \text{add} T$, and $g \in \text{Ext}_A^1(\tau T^0, \tau T^1)$ such that

$$f = \text{Ext}_A^1(T, g), \quad I_C^1 = \text{Ext}_A^1(T, \tau T^1), \quad I_C^0 = \text{Ext}_A^1(T, \tau T^0).$$
Applying $\text{Tor}_2^C(\cdot, T)$ to sequence (11) and using Theorem 2.1 we obtain a long exact sequence
\[ \text{Tor}_2^C(I_1^1, T) \longrightarrow M \longrightarrow \tau T^0 \longrightarrow \tau T^1 \longrightarrow \text{Ext}^1_A(T, M) \otimes_C T. \]
Observe that by the same theorem the last term in the sequence above is zero, likewise $\text{Tor}_2^C(I_1^1, T) = 0$, because $T$ as a left $C$-module has projective dimension at most one. Thus we obtain a short exact sequence in mod $A$
\[ 0 \longrightarrow M \longrightarrow \tau T^0 \longrightarrow \tau T^1 \longrightarrow 0 \]
which induces a triangle
\[ \tau T^1[-1] \longrightarrow M \longrightarrow \tau T^0 \longrightarrow \tau T^1 \]
in the cluster category. Applying $\text{Ext}^1_{C_A}(T, -)$ to this triangle we obtain an exact sequence in mod $B$
\[ \text{Ext}^1_{C_A}(T, \tau T^1[-1]) \longrightarrow \text{Ext}^1_{C_A}(T, M) \longrightarrow \text{Ext}^1_{C_A}(T, \tau T^0) \xrightarrow{g^*} \text{Ext}^1_{C_A}(T, \tau T^1). \]
Observe that because $T$ is a tilting object in $C_A$, we have $\text{Ext}^1_{C_A}(T, \tau T^1[-1]) = 0$. Moreover, equation (10) yields $\text{Ext}^1_{C_A}(T, \tau T^0) = I_B^0$ and $\text{Ext}^1_{C_A}(T, \tau T^1) = I_B^1$. Thus,
\[ \text{Ext}^1_{C_A}(T, M) = \ker \text{Ext}^1_{C_A}(T, g) : I_B^0 \to I_B^1. \]
On the other hand, applying the coinduction functor to sequence (11) we obtain
\[ 0 \longrightarrow D(B \otimes_C D\text{Ext}^1_A(T, M)) \longrightarrow I_B^0 \xrightarrow{D(1 \otimes Dg)} I_B^1. \]
Hence, we see that
\[ D(B \otimes_C D\text{Ext}^1_A(T, M)) = \ker D(1 \otimes Dg) : I_B^0 \to I_B^1. \]
Because $I_B^0$ is injective, both maps $\text{Ext}^1_{C_A}(T, g)$ and $D(1 \otimes Dg)$ are determined by their preimages of $\text{soc} I_B^1$. But since $\text{soc} I_B^1 = \text{soc} I_C^1$, we have
\[ \text{Ext}^1_{C_A}(T, g)^{-1}(\text{soc} I_B^1) = \text{Ext}^1_{C}(T, g)^{-1}(\text{soc} I_C^1) = D(B \otimes_C D\text{Ext}^1_A(T, g))^{-1}(\text{soc} I_B^1). \]
Thus we have a commutative diagram
\[ \begin{array}{ccc}
0 & \longrightarrow & \text{Ext}^1_{C_A}(T, M) \\
& & \downarrow h \\
0 & \longrightarrow & D(B \otimes_C D\text{Ext}^1_A(T, M))
\end{array} \quad \begin{array}{ccc}
I_B^0 & \xrightarrow{D(1 \otimes Dg)} & I_B^1 \\
& & \parallel \\
& & \text{Ext}^1_{C_A}(T, g) \equiv D(B \otimes_C D\text{Ext}^1_A(T, g))
\end{array} \]
and $h$ is an isomorphism by the Five Lemma. This shows that for every $M \in \mathcal{F}(T)$ we have $\text{Ext}^1_{C_A}(T, M) \cong D(B \otimes_C D\text{Ext}^1_A(T, M))$, and finishes the proof of the theorem. 

**Corollary 6.4.** Let $A$ be a hereditary algebra and $T \in \text{mod } A$ a basic tilting module. Let $C_A$ be the cluster category of $A$, $C = \text{End}_A T$ be the corresponding tilted algebra, and $B = C \ltimes E$ the corresponding cluster-tilted algebra. Then
\[ D(B \otimes_C DM) \cong \begin{cases} 
\text{Ext}^1_{C_A}(T, \text{Tor}_1^C(M, T)) & \text{if } M \in \mathcal{X}(T) \\
M & \text{if } M \in \mathcal{Y}(T)
\end{cases} \]
for every $M \in \text{ind } C$. 

Proof. The proof is similar to that of Corollary 6.2 and we omit it.

Example 6.5. Let $A$ be the path algebra of the following quiver.

\[
\begin{array}{ccccccc}
1 & \xleftarrow{\beta} & 2 & \xleftarrow{\alpha} & 4 & \xleftarrow{\gamma} & 5 \\
& & 3 & \xrightarrow{\epsilon} & 6 & \xrightarrow{\delta} & \\
& & \xrightarrow{\rho} & & \xrightarrow{\omega} & \xrightarrow{\sigma} & \xrightarrow{\omega}
\end{array}
\]

Let

\[ T = 1 \oplus \frac{5}{2} \oplus \frac{4}{2} \oplus \frac{5}{6} \oplus \frac{4}{6} \oplus 5 \]

be the tilting $A$-module. The Auslander-Reiten quiver of mod $A$ is shown at the top of Figure 1. The modules belonging to $\mathcal{T}(T)$ are in the dark shaded regions enclosed by a solid line, while modules belonging to $\mathcal{F}(T)$ are in the light shaded regions enclosed by a dotted line.

Then the corresponding tilted algebra $C = \text{End}_A T$ is the algebra of the following quiver with relations.

\[
\begin{array}{ccccccc}
1 & \xleftarrow{\beta} & 2 & \xleftarrow{\alpha} & 4 & \xleftarrow{\gamma} & 5 & \xleftarrow{\delta} & 6 \\
& & 3 & \xrightarrow{\epsilon} & & & & \\
& & \xrightarrow{\rho} & & \xrightarrow{\omega} & \xrightarrow{\sigma} & \xrightarrow{\omega}
\end{array}
\]

\[ \alpha \beta = 0 \]

\[ \delta \gamma \alpha = \epsilon \sigma. \]

The Auslander-Reiten quiver of mod $C$ is shown in the middle of Figure 1. The modules belonging to $\mathcal{Y}(T)$ are in the dark shaded regions enclosed by a solid line, while the modules belonging to $\mathcal{X}(T)$ are in the light shaded regions enclosed by a dotted line.

The cluster-tilted algebra $B = C \ltimes E$ is represented by the following quiver with relations.

\[
\begin{array}{ccccccc}
1 & \xleftarrow{\beta} & 2 & \xleftarrow{\alpha} & 4 & \xleftarrow{\gamma} & 5 & \xleftarrow{\delta} & 6 \\
& & 3 & \xrightarrow{\epsilon} & & & & \\
& & \xrightarrow{\rho} & & \xrightarrow{\omega} & \xrightarrow{\sigma} & \xrightarrow{\omega}
\end{array}
\]

\[ \alpha \beta = \omega \alpha = 0 \]

\[ \gamma \alpha \rho = \alpha \rho \delta = 0 \]

\[ \sigma \rho = \rho \epsilon = 0 \]

\[ \beta \omega = \rho \delta \gamma \]

\[ \delta \gamma \alpha = \epsilon \sigma. \]

The Auslander-Reiten quiver of mod $B$ is shown at the bottom of Figure 1 where we identify the modules which have the same labels. The modules in the dark shaded regions enclosed by a solid line correspond to the set $\{ Y \otimes_C B \mid Y \in \mathcal{Y}(T) \}$, while those in the light shaded regions enclosed by a dotted line correspond to the set $\{ D(B \otimes_C DX) \mid X \in \mathcal{X}(T) \}$. Note that there are four modules that lie in both sets. As stated in Theorems 6.1 and 6.3 the shape and relative position of $\mathcal{T}(T)$ and $\mathcal{F}(T)$ in mod $A$ correspond exactly to the set of induced $\mathcal{Y}(T)$-modules and the set of coinduced $\mathcal{X}(T)$-modules respectively. Moreover, if we apply $\tau_B^{-1}$ to the set of modules $\{ D(B \otimes_C DX) \mid X \in \mathcal{X}(T) \}$, then their position relative to the induced $\mathcal{Y}(T)$ modules will correspond exactly to the position of $\mathcal{F}(T)$ relative to $\mathcal{T}(T)$ in mod $A$.

7. Which Modules are Induced or Coinduced

If we want to study the module category of a cluster-tilted algebra via the induction and coinduction functors, then it is natural to ask which modules in a cluster-tilted algebra are actually induced or coinduced from the modules over some tilted algebra. Recall from
Figure 1. Auslander-Reiten quivers of $\text{mod } A$ (top), $\text{mod } C$ (middle) and $\text{mod } B$ (bottom).
Theorem 2.12 that, given a cluster-tilted algebra $B$, every local slice $\Sigma$ gives rise to a tilted algebra $C = B/\text{Ann} \Sigma$, whose relation extension is $B$.

**Definition 7.1.** Let $B$ be a cluster-tilted algebra and $M$ a $B$-module.

1. $M$ is said to be **induced from some tilted algebra** if there exists a tilted algebra $C$ and a $C$-module $X$ such that $B$ is the relation extension of $C$ and $M = X \otimes_C B$.

2. $M$ is said to be **coinduced from some tilted algebra** if there exists a tilted algebra $C$ and a $C$-module $X$ such that $B$ is the relation extension of $C$ and $M = D(B \otimes_C DM)$.

We begin by looking at algebras of finite representation type.

**Theorem 7.2.** If $B$ is a cluster-tilted algebra of finite representation type then every indecomposable $B$-module $M$ is both induced and coinduced from some tilted algebra $C$, depending on $M$.

**Proof.** If $B$ is of finite representation type and $M \in \text{ind} B$ then by Theorem 2.13 there exists a local slice $\Sigma \in \Gamma(\text{mod} B)$ containing $M$. Theorem 2.12 implies that there is a tilted algebra $C$ such that $\Sigma$ is a slice in $\Gamma(\text{mod} C)$ and $B$ is the relation extension of $C$. Hence, $M$ is an indecomposable $C$-module lying on a slice, which means $\text{id}_C M \leq 1$ and $\text{pd}_C M \leq 1$. It follows from Proposition 4.2 that $M \cong M \otimes_C B \cong D(B \otimes_C DM)$. Therefore, $M \in \text{ind} B$ is both induced and coinduced from the same module $M \in \text{ind} C$, for some tilted algebra $C$. □

Let us make the following observation.

**Proposition 7.3.** Suppose $B$ is a cluster-tilted algebra and $M$ is an indecomposable $B$-module. If $M$ is also an indecomposable $C$-module, for some tilted algebra $C$, whose relation extension is $B$, then $M$ is induced or coinduced.

**Proof.** Observe that if $M$ is a $C$-module, then Proposition 2.3(b) implies that $\text{id}_C M \leq 1$ or $\text{pd}_C M \leq 1$. In the first case $M \cong M \otimes_C B$ and in the second one $M \cong D(B \otimes_C B)$ by Proposition 4.2. Hence, in either case $M$ is induced or coinduced from a $C$-module. □

Therefore, it makes sense to ask which indecomposable modules over a cluster-tilted algebra are also indecomposable modules over a tilted algebra.

**Theorem 7.4.** Let $B$ be a cluster-tilted algebra. Then for every transjective indecomposable $B$-module $M$, there exists a tilted algebra $C$, such that $B$ is the relation extension of $C$, and $M$ is an indecomposable $C$-module. In particular, every transjective $B$-module is induced or coinduced from $C$.

**Proof.** We will show that if $M$ is a transjective indecomposable $B$-module then $M$ or $\tau_B^{-1} M$ lies in a local slice in $\text{mod} B$. According to Corollary 4.3 this will prove the Theorem.

Let $A$ be a hereditary algebra and $T \in \mathcal{C}_A$ a cluster-tilting object such that $B = \text{End}_{\mathcal{C}_A} T$. Let $M$ be an indecomposable $B$-module lying in the transjective component $\mathcal{T}$ of $\Gamma(\text{mod} B)$, and let $\tilde{M} \in \mathcal{C}_A$ be an indecomposable object such that $\text{Hom}_{\mathcal{C}_A}(T, \tilde{M}) = M$. Finally, let $\tilde{\Sigma} = \Sigma(\rightarrow M)$ be the full subquiver of the Auslander-Reiten of $\mathcal{C}_A$ defined in section 2.4.

Since $B \cong \text{End}_{\mathcal{C}_A}(\tau_A^\ell T)$, for all $\ell \in \mathbb{Z}$, we may assume without loss of generality that $\tilde{\Sigma}$ lies in the preprojective component of $\text{mod} A$. Furthermore, we may assume that every preprojective successor of $\tilde{\Sigma}$ in $\text{mod} A$ is sincere. Indeed, this follows from the fact that there are only finitely many (isoclasses of) indecomposable preprojective $A$-modules that
are not sincere. For tame algebras this holds, because non-sincere modules are supported on a Dynkin quiver, and for wild algebras see [Ke].

Now since \( \tilde{M} \) is a sincere \( A \)-module, Proposition 2.9 implies that \( \tilde{\Sigma} \) is a slice in \( \text{mod} \, A \), and therefore \( \tilde{\Sigma} \) is a local slice in \( C_A \). Let \( \Sigma = \text{Hom}_{C_A}(T, \tilde{\Sigma}) \). Then \( M \in \Sigma \), and thus, if \( \Sigma \) is a local slice in \( \text{mod} \, B \), we are done.

Suppose to the contrary that \( \Sigma \) is not a local slice. Then Lemma 2.14 implies that \( \tilde{\Sigma} \) contains an indecomposable summand \( \tau_{C_A} T_i \) of \( \tau_{C_A} C \). Let \( \tilde{\Sigma}' = \Sigma(T_i \rightarrow) \) in \( C_A \). Then \( \tilde{\Sigma}' \) contains \( \tau_{C_A}^{-1} \tilde{M} \). Since \( T_i \) is sincere, it again follows from Proposition 2.9 that \( \tilde{\Sigma}' \) is a local slice in \( C_A \).

Moreover \( \tilde{\Sigma}' \) cannot contain any summands of \( \tau_{C_A} T \), because if it did, there would be a sectional path from \( T_i \) to a summand of \( \tau_{C_A} T \), hence \( \text{Hom}_{C_A}(T_i, \tau_{C_A} T) \neq 0 \), which is impossible, since \( T \) is a cluster-tilting object. Therefore Lemma 2.14 implies that \( \text{Hom}_{C_A}(T, \tilde{\Sigma}') \) is a local slice in \( \text{mod} \, B \) containing \( \tau_{B}^{-1} M = \text{Hom}_{C_A}(T, \tau_{C_A}^{-1} \tilde{M}) \).

Following [R2], we say that a cluster-tilted algebra \( B \) is *cluster-concealed* if \( B = \text{End}_{C_A}(T) \) where \( T \) is obtained from a preprojective \( A \)-module. This means that all projective \( B \)-modules lie in the transjective component of \( \Gamma(\text{mod} \, B) \). In this case, we show that the theorem above holds not only for the transjective modules but for all \( B \)-modules.

**Theorem 7.5.** Let \( B \) be a cluster-concealed algebra. Then for every indecomposable \( B \)-module \( M \) there exists a tilted algebra \( C \) whose relation extension is \( B \), such that \( M \) is an indecomposable \( C \)-module. Moreover, for all non-transjective modules one can take the same \( C \).

In particular, every \( B \)-module is induced or coinduced from some tilted algebra.

**Proof.** Observe that by Theorem 7.4 it suffices to consider the case when \( M \) does not belong to the transjective component of \( \text{mod} \, B \). In this case, \( B \) is of infinite representation type.

Because \( B \) is cluster-concealed there exists a hereditary algebra \( A \), and a preprojective tilting \( A \)-module \( T \) such that \( B \cong \text{End}_{C_A}(T) \). Observe that \( A \) is of infinite representation type. Let \( C = \text{End}_{A}(T) \) be the corresponding tilted algebra. Then \( B \) is the relation extension of \( C \), thus \( B = C \ltimes E \), where \( E = \text{Ext}_{C}^{2}(DC, C) \). Let \( R_{A} \) be the set of all regular \( A \)-modules. It is nonempty because \( A \) is of infinite representation type. It follows from Theorem 2.2(a) that \( R_{A} \in \mathcal{T}(T) \). According to Theorem 2.2(b) the set of regular \( C \)-modules \( R_{C} \) is obtained from \( R_{A} \) by applying the functor \( \text{Hom}_{A}(T, -) \). Also, because of Theorem 2.5, the set of regular \( B \)-modules \( R_{B} \) is obtained from \( R_{A} \) by applying \( \text{Hom}_{C_A}(T, -) \). Hence, given \( M \in R_{B} \) there exists \( \tilde{M} \in R_{A} \) such that \( \text{Hom}_{C_A}(T, \tilde{M}) \cong M \). Because \( R_{A} \in \mathcal{T}(T) \), Theorem 6.1 implies that \( M \cong \text{Hom}_{A}(T, \tilde{M}) \otimes_{C} B \). Hence, \( M \) is induced from the indecomposable \( C \)-module \( \text{Hom}_{A}(T, \tilde{M}) \), and now it remains to show that \( M \) is actually an indecomposable \( C \)-module itself, that is \( M \cong \text{Hom}_{A}(T, \tilde{M}) \). It follows from Theorem 2.2(c) that \( \text{id}_{C} \text{Hom}_{A}(T, \tilde{M}) \leq 1 \), so Proposition 4.2(a) implies that

\[
M \cong \text{Hom}_{A}(T, \tilde{M}) \otimes_{C} B \cong \text{Hom}_{A}(T, \tilde{M}).
\]

This shows that \( M \) is an indecomposable \( C \)-module.

The next result describes a situation when all modules over a cluster-tilted algebra of tame type are induced or coinduced from some tilted algebra.

**Theorem 7.6.** Let \( B \) be a tame cluster-tilted algebra. Let \( S_{B} \) be a tube in \( \text{mod} \, B \) and let \( P_{B}(1), P_{B}(2), \ldots, P_{B}(\ell) \)
denote all distinct indecomposable projective $B$-modules belonging to $\mathcal{S}_B$. If
\[ \text{Hom}_B(P_B(i), P_B(j)) = 0 \text{ for all } i \neq j \text{ and } 1 \leq i, j \leq \ell \]
then every module in $\mathcal{S}_B$ is induced or coinduced from the same tilted algebra $C$.

**Proof.** Let $A$ be a hereditary algebra and $T$ a tilting $A$-module such that $B = \text{End}_C(T)$. Thus $A$ is tame, and we can suppose without loss of generality that $T$ has no preinjective summands. The regular components of $\text{mod } A$ form a family of pairwise orthogonal tubes. Let $\mathcal{S}_A$ be the tube in $\text{mod } A$ whose image under $\text{Hom}_C(T, -)$ is the tube $\mathcal{S}_B$ in the statement of the theorem. Let $r$ denote the rank of the tube $\mathcal{S}_A$. Let $\mathcal{S}_C$ denote the skew tube in $\text{mod } C$ given as the image of $\mathcal{S}_A$ under the functor $\text{Hom}_A(T, -)$. Thus $\mathcal{S}_C$ lies inside $\mathcal{Y}(T)$, which implies that each module in $\mathcal{S}_C$ has projective dimension at most one, by Proposition 2.3, and therefore the coinduction functor is the identity on $\mathcal{S}_C$, by Proposition 4.2.

Theorem 6.1 yields the following commutative diagram.

Let $T_1, T_2, \ldots, T_\ell$ be the indecomposable summands of $T$ that lie inside $\mathcal{S}_A$, such that $P_B(i) = \text{Hom}_C(A(T, T_i))$, for $i = 1, 2, \ldots, \ell$, are the indecomposable projective modules in $\mathcal{S}_B$. Because of our assumption $\text{Hom}_A(T_i, T_j) = 0$, if $i \neq j$, we have that each $T_i$ lies on the mouth of $\mathcal{S}_A$, see for example [SimSko3, Proposition XII.2.1].

The local configuration in the Auslander-Reiten quiver of $\mathcal{S}_A$ is the following.

```
  \cdots \rightarrow I_B(i) \rightarrow \tau_B \text{rad } P_B(i) \rightarrow \cdots
  \cdots \rightarrow \tau_B \text{rad } P_B(i) \rightarrow \cdots
  \cdots \rightarrow \cdots \rightarrow \cdots
```

The corresponding local configuration in the Auslander-Reiten quiver of $\mathcal{S}_B$ is the following.

```
  \cdots \rightarrow I_B(i) \rightarrow \tau_B \text{rad } P_B(i) \rightarrow \cdots
  \cdots \rightarrow \tau_B \text{rad } P_B(i) \rightarrow \cdots
  \cdots \rightarrow \cdots \rightarrow \cdots
```

Since $\text{Ext}^1_A(T_i, -) \cong D\text{Hom}_A(-, \tau T_i)$, and $\tau T_i$ lies on the mouth of $\mathcal{S}_A$, we see that $\mathcal{S}_A \cap \mathcal{T}(T)$ consists of the $r - \ell$ corays not ending in one of the $\tau T_i$, $i = 1, 2, \ldots, \ell$. Therefore $\mathcal{S}_C \otimes_C B$ has $r - \ell$ corays, because of our commutative diagram. So these $r - \ell$ corays are in the image of the induction functor $- \otimes_C B$. 

Moreover the $\ell$ corays in $S_B$ that are not in the image of the induction functor are precisely those ending in $\tau_B \text{rad} P_B(i)$, $i = 1, 2, \ldots, \ell$. We will show that these corays are equal to the corays in $S_C$ ending in $\tau_C \text{rad} P_C(i)$, which implies that these corays are coinduced.

Since $I_B(i) = \text{Hom}_{C_A}(T, \tau_B^2 T)$ we have

\begin{equation}
\tau_B \text{rad} P_B(i) = I_B(i)/S(i).
\end{equation}

By our assumption on $T$, we have $\text{Hom}_A(T, T) = \text{Hom}_A(T_i, T_i)$ and thus $I_C(i) = S(i)$ is simple. Moreover, by Proposition 3.6(b), there is a short exact sequence in mod $B$ of the form

\begin{equation}
0 \longrightarrow I_C(i) \longrightarrow I_B(i) \longrightarrow \tau_C \Omega C I_C(i) \longrightarrow 0,
\end{equation}

and thus

\begin{equation}
I_B(i)/S(i) \cong \tau_C \Omega C I_C(i).
\end{equation}

Again using that $I_C(i)$ is simple, we see that

\begin{equation}
\Omega C I_C(i) = \text{rad} P_C(i).
\end{equation}

Combining equations (12)-(14) yields

\begin{equation}
\tau_B \text{rad} P_B(i) = \tau_C \text{rad} P_C(i).
\end{equation}

Finally, let $M$ be any indecomposable $C$-module on the coray in $S_C$ ending in $P_C(i)$, but $M \neq P_C(i)$. Then $M \otimes_C B$ lies on the coray in $S_B$ ending in $P_B(i)$. Lemma 3.8 implies that

\begin{equation}
\tau_B(M \otimes_C B) = D(B \otimes_C D(\tau C M)) = \tau C M,
\end{equation}

where the last identity holds because the coinduction functor is the identity on the tube $S_C$. This shows that the $\tau_B$-translate of the coray in $S_B$ ending in $P_B(i)$ is equal to the coray in $S_C$ ending in $\tau_C \text{rad} P_C(i)$. In particular the modules on this coray are coinduced from $C$.

This finishes the proof of the theorem. \qed

**Remark.** There are cluster-tilted algebras $B$ with indecomposable modules that are not induced and not coinduced from any tilted algebra. We give an example below.

**Example 7.7.** Let $B$ be a cluster-tilted algebra given by the following quiver with relations.

\[
\begin{array}{c}
1 \xrightarrow{\alpha} 3 \\
\downarrow \beta \quad \alpha \beta = \beta \epsilon = \epsilon \alpha = 0 \\
3 \xrightarrow{\gamma} 2 \xleftarrow{\sigma} 4 \\
\downarrow \delta \quad \gamma \delta = \delta \sigma = \sigma \gamma = 0.
\end{array}
\]

Then there are exactly two tilted algebras $C$ and $C'$, both of infinite representation type, whose relation extension is $B$. $C$ and $C'$ can be represented by the following quivers with relations.
There is a tube in $\Gamma(\text{mod } B)$ of rank four containing three distinct projective modules. We describe it below and identify the modules that have the same label. We will show that the four modules emphasized in bold are not induced and not coinduced.

The corresponding skew tube in $\Gamma(\text{mod } C)$ is given below. Observe that it consists of one coray ending in the projective at vertex 2, labeled $\frac{2}{3} \frac{4}{5} \frac{3}{4}$, and four rays starting in $\frac{2}{3} \frac{4}{5} \frac{3}{4}$, $\frac{1}{5} \frac{4}{3} \frac{1}{2}$, $\frac{3}{1} \frac{5}{2} \frac{1}{3}$, and $\frac{4}{3} \frac{1}{5} \frac{2}{3}$. Let $E = \tau^{-1}\Omega^{-1}C$ and $DE = \tau\Omega DC$, then we make the following computation.

$$E : \frac{3}{4} \oplus \frac{3}{4} \oplus \frac{3}{4} \oplus 2 \oplus \frac{3}{4} \quad \quad \quad DE = 0 \oplus 4 \oplus \frac{2}{3} \oplus \frac{2}{3} \oplus 0$$
Let $O_C$ denote the coray in $\Gamma(\text{mod } C)$ ending in the projective at vertex 2. Observe that if we induce the modules in $O_C$, that is apply $D\operatorname{Hom}_C(-, DB)$, then we obtain a coray in the tube of $\Gamma(\text{mod } B)$ that ends in the projective $B$-module at vertex 2. Recall that there is an isomorphism of $C$-modules $D\operatorname{Hom}_C(M, DB) \cong M \oplus D\operatorname{Hom}_C(M, DE)$ for every $M \in \text{mod } C$. On the other hand coinduction $\operatorname{Hom}_C(B, -)$ of modules in $O_C$ will act as the identity map, because there is a $C$-module isomorphism $\operatorname{Hom}_C(B, M) \cong M \oplus \operatorname{Hom}_C(E, M)$ and the last summand is zero for all $M \in O_C$. Therefore, we see the coray $O_C$ appearing in $\Gamma(\text{mod } B)$. Finally, the only module in the tube above that does not belong to $O_C$ is the simple at 4. Observe, that this module is also a projective $C$-module, so inducing it we obtain the corresponding projective $B$-module 4.

Similarly, in $\Gamma(\text{mod } C')$ there is a skew tube consisting of four corays and one ray starting in $\frac{1}{3}$, the injective $C'$-module at vertex 4. Denote this ray by $R_{C'}$. Analogous calculations yield that the ray in $\Gamma(\text{mod } B)$ starting in $\frac{2}{3}$, the injective $B$-module, is coinduced from $R_{C'}$. But the induction of $R_{C'}$ acts as the identity map, so we see this exact same ray appearing in $\Gamma(\text{mod } B)$. Observe that every module on this ray is indeed an indecomposable $C'$-module. Finally, the simple injective $C'$-module at vertex 2, belongs to this skew tube, and its induction is again the simple module supported at vertex 2.

In particular we observe that the $B$-modules which make up the mesh emphasized in bold are not induced and not coinduced from any tilted algebra. Moreover, as one goes down the tube in $\Gamma(\text{mod } B)$ there will appear infinitely many such meshes, where no module is induced or coinduced.
