Abstract

In this paper, we construct a new exact analytic solution for Anti-de Sitter-Nonlinear electrodynamics (AdS-NED) black hole in four dimensions. We study tunneling of vector particles from novel AdS-NED black hole to find Hawking temperature as well as its thermodynamical properties in usual and extended phase space. Then we explore the properties of pressure-volume criticality by analyzing the phase diagram and its free energy. Finally, we investigate the Joule-Thomson coefficient, in which the inversion curve of warming and cooling are studied, and the ratio between the inverse temperature and critical temperature are computed in our black hole solution.

I. INTRODUCTION

Black holes are a fascinating part of our universe and also in general relativity. Recently, astronomers stumbled upon a fascinating finding: thousands of black holes likely exist near the center of our galaxy using some of the data was collected nearly 20 years ago by NASA’s Chandra X-Ray Observatory [1]. In near future Event Horizon Telescope (EHT) will resolve the event horizon of the central black hole using radio data [2]. Black holes are the solutions of Einstein’s field equations, and asymptotically flat and stationary black holes are the simple form of them which are only showed the property of mass, angular momentum and charges. One of the big problem in general relativity is the singularities which occur in the beginning of the universe and also in black hole solutions or curvature singularities [3, 4]. Maxwell theory also has similar singularities. To remove the singularities, one can use the modified Maxwell theory or nonlinear electrodynamics, which gives the Maxwell filed at weak field limits. Another interest in nonlinear electrodynamics is because of the possibility of providing quantum gravity corrections to Maxwell fields. For this purposes, large class of regular black holes are studied in literature where there is no singularities. The first one is studied by Bardeen in 1968 and known as Bardeen black hole [5]. Then Ayon-Beato et al. extended it using the nonlinear magnetic monopole field [6]. Furthermore, Dymnikova also studied nonsingular black holes that are connected with a de Sitter spacetime [7]. Another example is the black hole solutions found by using the noncommutative geometry [8]. There have recently been many studies on nonlinear electrodynamics in the black holes [9–18].

Since the Maldacena’s idea of AdS/CFT correspondence [19], where the gravity theory in AdS space with a conformal field theory (CFT) living on the boundary, black hole’s solutions in the AdS spacetime have became more important [20]. The AdS/CFT duality provides us to calculate the thermodynamics properties of the AdS black holes within a certain boundary of CFT in the limit of high temperature so that the AdS/CFT correspondence is an interesting tool to investigate strongly coupled field theories such as superconductors [21].

Black holes are thermal systems, so that black holes have temperature and entropy [22–37]. Another important development of the thermodynamics of black holes is due to the AdS space time and phase transitions. First, Hawking-Page showed the phase transition between the Schwarzschild-AdS black hole and thermal AdS spacetime [38]. Then Chamblin et al. studied the charged AdS black holes and its relation to the liquid-gas system [39]. Afterwards, extended phase space is used to investigate the renenrart phase transition and show the relation with the van der Waals fluids that provide interesting area of black hole chemistry by treating the cosmological constant as a variable thermodynamic pressure and its conjugate quantity with thermodynamic volume [40–42]. There are many application papers of studying phase transitions, P-V criticality on AdS black holes in literatures [43–84] and therein.

Moreover, recently Joule-Thomson (JT) expansion is cleverly applied to black holes in AdS spacetime by Ökcü and Aydiner [85, 86]. The JT expansion occurs when there is a constant enthalpy which is a mass for black holes. JT expansion is used as a isenthalpic tool to show the thermal expansion where there is heating and cooling regimes. Note that the pressure decreases for the expanding thermal system with a temperature T so that the inversion temperature is obtained where the JT coeficient vanishes and at the inversion temperature $T_i$, and corresponding inversion pressure $P_i$, there is a cooling and heating transition [87–89].

Our main motivation is to find new AdS black hole solution in NED and clarify influence of the NED on the thermodynamics, P-V criticality and JT expansion of the novel AdS-NED black hole.

This paper is organized as follows. In Sec.II, we construct a novel AdS black hole using the nonlinear electrodynamics by introducing a new model of NED Lagrangian, and solve the corresponding energy-momentum tensor within the Einstein’s field equations. In Sec. III, we calculate Hawking temperature using the complex path (or Hamilton-Jacobi) approach by the tunneling spin-1 vector particles from the novel AdS black hole. In Sec. IV, we investigate the thermodynamics properties of the novel AdS-NED black hole in an usual and extended phases. In Sec. V, we study the P-V criticality and Gibbs free energy of novel AdS-NED black hole. In Sec. VI, we investigate the JT expansion and isenthalpy curve for the novel AdS-NED black hole. We conclude the manuscript in Sec. VII.

II. BLACK HOLE SOLUTION IN NED

We consider the following action

$$S = \frac{1}{16\pi G} \int d^4x \sqrt{-g} \left( R - 2\Lambda - \mathcal{L}(\mathcal{F}) \right), \quad (1)$$

where the cosmological constant $\Lambda = -3\ell^{-2}$ with $\ell$ the AdS radius. $\mathcal{L}$ is a function of $\mathcal{F}$ and we define $\mathcal{F} \equiv F^2$ while $F = dA$ is a field strength of the electromagnetic field. Then the covariant equations of motion deduced from the above action are

$$\nabla_\mu \left( \mathcal{L}_\mathcal{F} F^{\mu\nu} \right) = 0, \quad R_{\mu\nu} - \frac{1}{2} (R - 2\Lambda) g_{\mu\nu} = T_{\mu\nu}, \quad (2)$$

where $\mathcal{L}_\mathcal{F} = \frac{\partial \mathcal{L}}{\partial \mathcal{F}}$ and the energy momentum tensor is

$$T_{\mu\nu} = 2 \left( \mathcal{L}_\mathcal{F} F^{\mu\nu} - \frac{1}{4} g_{\mu\nu} \mathcal{L} \right). \quad (3)$$

In our construction, we present new Lagrangian density for NED

$$\mathcal{L}(\mathcal{F}) = -2 \ln \left( \frac{1 - \alpha^2 \sqrt{\mathcal{F}}}{\alpha^4} \right) - 2 \frac{\sqrt{\mathcal{F}}}{\alpha^2}. \quad (4)$$

We note that in a weak field limit, i.e., $\alpha \to 0$, the vector field becomes $\mathcal{L} \sim \mathcal{F}$, which goes back to the linear Maxwell field theory. We are interested in the static spherical symmetric AdS black holes with NED. To this end, we consider that the most general ansatz of the geometry and the electromagnetic field

$$ds^2 = -f(r) dt^2 + \frac{dr^2}{f(r)} + r^2 (d\theta^2 + \sin^2 \theta d\phi^2), \quad (5)$$
\( A = -Q_m \cos \theta d\phi, \) 
\( (6) \)

where \( Q_m = \frac{1}{4\pi} \int_{S^2} F \) is the total magnetic charge carried by the black hole. Here the square of the field strength is given by \( F = F^2 = \frac{2q^2}{r^2} = \frac{q^2}{r^2} \) where \( q = 2Q_m \) can be treated as the magnetic monopole charge. Moreover, to solve the equation of motion, we consider the redshift function as

\[
f(r) = 1 - \frac{2m(r)}{r}. \]
\( (7) \)

Subsequently, in the \( tt \) component of Einstein equation\(^1\),

\[
G_{tt} + \Lambda g_{tt} = -2\mathcal{L}(\mathcal{F})g_{tt}, \]
\( (8) \)

we have

\[
G_{tt} = -2 \left( 1 - \frac{2m(r)}{r} \right) \frac{m'(r)}{r^2} \]
\( (9) \)

and

\[
\mathcal{L}(\mathcal{F}) = \frac{1}{\alpha^4} \left[ -\frac{\sqrt{2\alpha^2} \lvert q \rvert}{r^2} + 2 \ln(2) - 2 \ln \left( -\frac{\sqrt{2\alpha^2} \lvert q \rvert}{r^2} + 2 \right) \right]. \]
\( (10) \)

For simplification, we rewrite \( \lvert q \rvert \) as \( q \) in the following studies.

Considering Eq.(9) and Eq.(10) into Eq.(8), we do the integration and obtain the function \( m(r) \) as

\[
m(r) = \frac{\Lambda r^3}{6} - \frac{\sqrt{2q}}{3\alpha^2} + \frac{2q^3}{3\alpha^4} \ln \frac{\sqrt{2r^2}}{q^2} - \frac{2^{5/4}q^{3/2}}{3\alpha} \arctanh \left( \frac{\alpha q^{1/2}}{2^{1/4}r} \right) + m_0, \]
\( (11) \)

where \( m_0 \) is an integral constant related with the mass of the black hole. Subsequently, according to Eq.(7), we get \( f(r) \) as

\[
f(r) = 1 - \frac{\Lambda r^2}{3} - \frac{2m_0}{r} + \frac{2\sqrt{2q}}{3\alpha^2} + \frac{4r^3}{3\alpha^4} \ln \left( 1 - \frac{q\alpha^2}{2r^2} \right) + \frac{2^{5/4}q^{3/2}}{3\alpha r} \arctanh \left( \frac{\alpha q^{1/2}}{2^{1/4}r} \right). \]
\( (12) \)

We note that when \( \alpha \to 0 \), \( f(r) \) goes back to the redshift function of RN-AdS black hole, \( f(r) = 1 - \frac{\Lambda r^2}{3} - \frac{2m_0}{r} + \frac{q^2}{r^2} \), as we expect. Defining the location of horizon, \( r_h \), which satisfies \( f(r_h) = 0 \), the integral constant \( m_0 \) is solved as

\[
m_0 = \frac{r_h}{2} - \frac{\Lambda r_h^3}{6} + \frac{\sqrt{2q}r_h}{3\alpha^2} + \frac{2r_h^3}{3\alpha^4} \ln \left( 1 - \frac{q\alpha^2}{2r_h^2} \right) + \frac{2^{5/4}q^{3/2}}{3\alpha r_h} \arctanh \left( \frac{\alpha q^{1/2}}{2^{1/4}r_h} \right) = M, \]
\( (13) \)

and \( M \) is the mass of our black hole solution.

### III. TUNNELING OF VECTOR PARTICLES AND HAWKING RADIATION

In this section, we investigate the tunneling of massive vector particles from the novel AdS-NED black hole and obtain the corresponding Hawking temperature via Hamilton-Jacobi equation with Wentzel, Kramers, Brillouin (WKB) approximation. For this purpose, we use the Proca equation that shows the behavior of the wave function of spin-1 field \( \Psi_\nu \) as follows \[29\]

\[
\frac{1}{\sqrt{-g}} \partial_\mu \left( \sqrt{-g} \Psi^{\mu \nu} \right) + \frac{m^2}{h^2} \Psi^{\nu} = 0, \]
\( (14) \)

\(^1\) We use the unit \( c = 8\pi G = 1 \).
where $m$ is the mass of the tunneling vector particle. In Eq. (14), we can define the second rank tensor as
\[
\Psi_{\mu\nu} = \partial_\mu \Psi_\nu - \partial_\nu \Psi_\mu.
\] (15)

After we use the ansatz of the WKB approximation for the spin-1 fields
\[
\Psi_\nu = C_\nu \exp \left( \frac{i}{\hbar} \left( S_0(t, r, \theta, \phi) + \hbar S_1(t, r, \theta, \phi) + \ldots \right) \right),
\] (16)

where $C_\nu = (C_1, C_2, C_3, C_4)$ are constants, $S_0(t, r, \theta, \phi)$ stands for the kinetic term (classical action) of the vector particles with the higher order action corrections $S_j(t, r, \theta, \phi)$. Symmetry of the spacetime provides us to use the Hamilton-Jacobi method by setting
\[
S_0(t, r, \theta, \phi) = -Et + R(r, \theta) + j\phi + k,
\] (17)

in leading order of the action. Here $E$ is energy of the vector particle and $j$ stands for angular momentum of the vector particles. Moreover, $k$ is used as a complex constant.

Solving the Proca equation (14) on the background of the black hole within (16) and (17), we obtain a set of equations in the lowest order in $\hbar$:
\[
-\frac{E}{r^2} \partial_t R C_1 - \frac{E}{r^2 f} \frac{\partial (\partial_t R) C_1}{r^2} - \frac{\sin^2 \theta \left( r^2 f (\partial_t R)^2 + m^2 r^2 + (\partial_t R)^2 \right)}{r^2 f \sin^2 \theta} C_4 - \frac{E j C_3}{r^2 f \sin^2 \theta} = 0,
\] (18)

\[
-\frac{f (\partial_t R) C_1}{r^2} - \frac{\sin^2 \theta f (\partial_t R)^2 - f (m^2 r^2 \sin^2 \theta + j^2) + E^2 r^2 \sin^2 \theta}{r^2 \sin^2 \theta} C_1 - \frac{f (\partial_t R) (\partial_t R) C_2}{r^2} - \frac{f j (\partial_t R) C_3}{r^2 \sin^2 \theta} - \frac{E (\partial_t R) C_4}{r^2 f} = 0,
\] (19)

\[
-\frac{j f (\partial_t R) C_1}{r^2 \sin^2 \theta} - \frac{j f (\partial_t R) C_2}{r^2 \sin^2 \theta} + \frac{f (\partial_t R)^2 - r^2 (-f^2 (\partial_t R)^2 - m^2 f + E)}{r^4 f \sin^2 \theta} C_3 - \frac{j E C_4}{r^2 f \sin^2 \theta} = 0,
\] (20)

To find the solution of these equations, we write them in a matrix form and use the property of transition to the transposed vector $\Psi (C_1, C_2, C_3, C_4)^T = 0$. Then the nonzero components are
\[
Y_{11} = Y_{24} = -E (\partial_t R),
\] (22)

\[
Y_{12} = Y_{34} = -\frac{E (\partial_t R)}{r^2 f},
\] (23)

\[
Y_{13} = Y_{44} = -\frac{E j}{r^2 f \sin^2 \theta},
\] (24)

\[
Y_{14} = -\frac{\sin^2 \theta \left( r^2 f (\partial_t R)^2 + m^2 r^2 + (\partial_t R)^2 \right) + j^2}{r^2 f \sin^2 \theta},
\] (25)

\[
Y_{21} = \frac{\sin^2 \theta f (\partial_t R)^2 - f (m^2 r^2 \sin^2 \theta + j^2) + E^2 r^2 \sin^2 \theta}{r^2 \sin^2 \theta},
\] (26)

\[
Y_{22} = Y_{31} = -\frac{f (\partial_t R) (\partial_t R)}{r^2},
\] (27)

\[
Y_{23} = Y_{41} = \frac{j f (\partial_t R)}{r^2 \sin \theta},
\] (28)

\[
Y_{24} = \frac{-\sin^2 \theta f (\partial_t R)^2 - f (m^2 r^2 \sin^2 \theta + j^2) + E^2 r^2 \sin^2 \theta}{r^2 \sin^2 \theta},
\] (29)

\[
Y_{33} = Y_{42} = \frac{j (\partial_t R)}{r^4 \sin^2 \theta},
\] (30)

\[
Y_{34} = \frac{f (\partial_t R)^2 - r^2 (-f^2 (\partial_t R)^2 - m^2 f + E)}{r^4 f \sin^2 \theta}.
\] (31)
The solution of these equation satisfying the condition $\det \mathcal{H} = 0$ is

$$m^2 \left[ \sin^2 \theta f (\partial \theta R)^2 + f^2 r^2 (\partial_r R)^2 + f \left( m^2 \sin^2 \theta r^2 + j^2 \right) - E^2 r^2 \sin \theta \right]^3 = 0,$$

where the radial equation $R$ is obtained non-trivially

$$R = \int \pm \sqrt{E^2 - f \left( m^2 + \left( \frac{\partial \theta R}{r^2} + \frac{j^2}{\sin \theta r^2} \right) \right)}.$$

We show the outgoing and ingoing particles by the signs of $\pm$. In the equation (33), there is a pole at the event horizon of the novel AdS-NED black hole so that we use the complex path integration method to solve it. The solution of the integral becomes

$$\text{Im} W_{\pm}(r) = \pm \frac{\pi}{\partial_r E} \left. \right|_{r=r_h}.$$ (34)

Afterwards, we can easily find the tunneling probabilities of the particles

$$P_{\text{emission}} = e^{-\frac{\pi}{\hbar} \text{Im} S_{\pm}} = e^{\left[ -\frac{\pi}{\hbar} \text{Im}(W_{\pm} + \text{Im} B) \right]},$$ (35)

$$P_{\text{absorption}} = e^{-\frac{\pi}{\hbar} \text{Im} S_{\pm}} = e^{\left[ -\frac{\pi}{\hbar} \text{Im}(W_{\pm} + \text{Im} B) \right]},$$ (36)

Note that black hole must absorb all the particles classically, so that we take the probability of the ingoing particles as $P_{\text{absorption}} = 1$. Next, the relation becomes $\text{Im} B = -\text{Im} W_-$ and use the $W_+ = -W_-$, tunneling rate of the massive vector particles are obtained as

$$\Gamma = P_{\text{emission}} = \exp \left( -\frac{4\pi}{\hbar} \text{Im} W_+ \right) = \exp \left( -\frac{4\pi}{\hbar (\partial_r f)} \left. \right|_{r=r_h} \right).$$ (37)

It is noted that $\Gamma$ equals to the Boltzmann factor. Hence the temperature of the novel AdS-NED black hole is

$$T = \left. \frac{\hbar (\partial_r f)}{4\pi} \right|_{r=r_h} = \frac{1}{4\pi r_h} - \frac{\Lambda r_h}{4\pi} - \frac{2r_h}{3\pi \alpha^4} + \frac{q}{3\sqrt{2\pi \alpha^2 r_h}} + \frac{\sqrt{2}(\sqrt{2}r_h^2 + q\alpha^2)}{3\pi \alpha^4 r_h} + \frac{r_h}{\pi \alpha^4} \ln \left( 1 - \frac{q\alpha^2}{\sqrt{2}r_h^2} \right).$$ (38)

### IV. PROPERTIES OF THERMODYNAMICS

After the Hawking temperature in hand, in this section, we shall study the thermodynamical properties of the black hole. We first focus on usual phase space and then we will study the thermodynamics in the extended phase space by defining the cosmological constant as the pressure [90, 91]

$$P = -\frac{\Lambda}{8\pi}.$$ (39)

**A. Thermodynamics in usual phase space**

The Hawking temperature of the novel AdS-NED black hole is given in (38) and the entropy is

$$S = \frac{A}{4} = \pi r_h^2.$$ (40)

The magnetical potential of the black holes is

$$\Phi = \left( \frac{\partial M}{\partial Q_m} \right)_S = \frac{25/4}{\alpha} \sqrt{q} \arctanh \left( \frac{\alpha \sqrt{q}}{2^{1/4} r_h} \right).$$ (41)
Furthermore, it is straightforward to check that the temperature also satisfies

\[ T = \left( \frac{\partial M}{\partial S} \right)_{Q_m}. \]  

(42)

Therefore, the first law of the black hole

\[ dM = TdS + \Phi dQ_m. \]  

(43)

is fulfilled. The heat capacity can be calculated by

\[ C_{Q_m} = T \left( \frac{\partial S}{\partial T} \right)_{Q_m} = -\frac{2\pi}{3\alpha^4} \left( 6\sqrt{2}\alpha^2q - 3\alpha^4 (\Lambda r_h^2 - 1) + 12r_h^2 \ln \left( 1 - \frac{\alpha^2}{\sqrt{2}r_h^2} \right) \right), \]  

(44)

which is required to be positive for the thermodynamical stability of the black hole.

**B. Thermodynamics in extended phase space**

In the extended phase space, due to the definition (39), the thermodynamic quantity conjugate to the pressure is the thermodynamic volume of black hole\[90, 91]\n
\[ V = \left( \frac{\partial M}{\partial P} \right)_{Q_m,S} = \frac{4\pi}{3} r_h^3. \]  

(45)

Then the extended first law of the thermodynamic is

\[ dM = TdS + \Phi dQ_m + VdP + \mathcal{A}d\alpha \]  

(46)

where \( T, \Phi \) and \( V \) are given previously and

\[ \mathcal{A} = \left( \frac{\partial M}{\partial \alpha} \right)_{S,P,Q} = -\frac{4\sqrt{2}}{3\alpha^3} q \ln \left( 1 - \frac{\alpha^2}{\sqrt{2}r_h^2} \right) - \frac{2\sqrt{2}}{3\alpha^4} (\alpha^4 - q^2) + \frac{4\alpha^3}{3\alpha^3} \ln \left( 1 - \frac{\alpha^2}{\sqrt{2}r_h^2} \right), \]  

(47)

is the conjugation of \( \alpha \) introduced to fulfill first law. Furthermore, we can derive the generalized Smarr relation of the novel AdS-NED black hole is

\[ M = 2TS + \Phi Q_m - 2PV + \frac{1}{2} \mathcal{A} \alpha, \]  

(48)

in terms of the dimensional analysis.

**V. THE \( P-V \) CRITICALITY AND GIBBS FREE ENERGY**

Then we move on to study the \( P-V \) critical properties, which was proposed in [42], of the novel AdS-NED black hole and compare with the Van der Waals fluid. To this end, we substitute the definition (39) into the temperature (38), then we reduce the state equation

\[ P = \frac{T}{2r_h} - \frac{1}{8\pi r_h^2} + \frac{1}{3\pi \alpha^4} - \frac{q}{6\sqrt{2}\pi \alpha^2 r_h^2} - \frac{q^2}{6\pi \alpha^4 r_h^2} - \frac{1}{2\pi \alpha^4} \ln \left( 1 - \frac{\alpha^2}{\sqrt{2}r_h^2} \right). \]  

(49)

According to the critical conditions

\[ \frac{\partial P}{\partial r_h} = \frac{\partial^2 P}{\partial r_h^2} = 0, \]  

(50)
we obtain that the unique critical point is located at

\[ r_{hc} = \sqrt{q(X + \frac{\alpha^2}{\sqrt{2}})}, \]  
\[ T_c = \frac{5\sqrt{2}\alpha^2X + 12\sqrt{2}\alpha^4q + 2\alpha^4 + 36qX}{\pi(3X + \sqrt{2}\alpha^2)^2}\sqrt{4qX + 2\sqrt{2}\alpha^2q} \]  
\[ P_c = \frac{8}{\alpha^3} - \frac{3}{qX + \frac{\alpha^2}{\sqrt{2}}} \left( \frac{2X + \sqrt{2}\alpha^2}{\alpha^4X} \right) + \frac{12\left(5\sqrt{2}\alpha^2X + 12\sqrt{2}\alpha^4q + 2\alpha^4 + 36qX\right)}{(3X + \sqrt{2}\alpha^2)^2}\left(2qX + \sqrt{2}\alpha^2q\right) \]  
\[ + \frac{12\ln\left(1 + \frac{\alpha^2}{\sqrt{2}X}\right)}{\alpha^4} + \frac{8}{X\left(2\alpha^2 + 2X\right)} - \frac{4\sqrt{2}}{\alpha^2\left(\sqrt{2}\alpha^2 + 2X\right)} \]  
where we have defined \( X = 3q + \sqrt{q(2\sqrt{2}\alpha^2 + 9q)} \). The explicit dependence of the critical points on the parameters are shown in figure 1 where in the plots the red and black lines corresponds to the fixed \( \alpha = 1 \) and \( q = 1 \), respectively. It is obvious that \( r_{hc} \) increases as both \( q \) and \( \alpha \) while \( T_c \) and \( P_c \) has totally opposite tendency.

We note that by defining the specific volume as \( v = \frac{2r_h}{3} \) [42], it is straightforward to obtain the relation

\[ \frac{P_cv}{T_c} = \frac{1}{8} \frac{\sqrt{2}\alpha^2X + 3q\left(\frac{\alpha^2}{3} + X\right)\ln\left(1 + \frac{\alpha^2}{\sqrt{2}X}\right)}{16\alpha^2 + 3q\left(\frac{\alpha^2}{3} + X\right)\ln\left(1 + \frac{\alpha^2}{\sqrt{2}X}\right)} \]  

from which the ratio is modified by the nonlinear electrodynamic term. It can be reduced to \( 3/8 \) as \( \alpha \to 0 \) for the Van der Waals fluid and predicted for any RN-AdS black hole.

In the following study, we will focus on \( q = \alpha = 1 \) without loss of generality, such that the critical points are \( (T_c = 0.04104, P_c = 0.002943) \). We plot the behavior between the pressure and horizon in figure 2. The temperature of the isothermal lines decreases from top to bottom. The two upper dotted lines are for \( T > T_c \) correspond to the ideal gas. The critical isotherm \( T = T_c \) is denoted by the solid black line and the lower solid dashed lines correspond to temperatures lower than \( T_c \). The \( P - V \) diagram is like the Van der Waals gas.
FIG. 3: Gibbs free energy and the temperature. The solid black line is for the critical pressure $P_c = 0.002943$ while the dotted blue lines and solid red lines are for $P > P_c$ and $P < P_c$, respectively. We set $q = \alpha = 1$.

Then we check the Helmholtz free energy which is defined as

$$F = M - TS = \frac{2^{5/4} q^{3/2}}{3\alpha} \arctanh \left( \frac{\alpha q^{1/2}}{2^{1/4} r} \right) + \frac{r_h}{4} - \frac{2\pi P}{3} r_h^3 - \frac{\sqrt{2} q}{6\alpha^2} r_h - \frac{r_h^3}{3\alpha^4} \ln \left( 1 - \frac{q\alpha^2}{\sqrt{2} r_h^2} \right). \quad (55)$$

We are interested in the fixed charged ensemble because this ensemble exhibits many interesting features. Similar study for the fixed potential ensemble can be straightforwardly generalized and we will not discuss it here. The behaviour of $F$ can be seen in figure 3. The black line is for the critical pressure $P_c = 0.002943$ while the dotted blue lines and solid red lines are for $P > P_c$ and $P < P_c$, respectively. The free energy presents a swallow tail behaviour in the cases with $P < P_c$, which means a first order transition between small black hole and large black hole occurring at some $T_0$ marked with green in the figure. For each $P_0$ lower than $P_c$, there is a related $T_0$ at which two black holes have equal free energy. Then we can draw a coexistence line in the $(P, T)$-plane above which the small black hole is physically flavor while the large black hole is below the line. Our coexistence line with $\alpha = q = 1$ is shown in figure 4 where the dot denotes $(T_0, P_0)$. We note that For the first order phase transition, the physical $P - r_h$ diagram should be modified by replacing the oscillating part by an isobar with the transition $T = T_0$. So the horizon the the small/large black hole with same free energy can be determined by using the Maxwells equal area law in the $P - r_h$ diagram\[43\].

FIG. 4: Coexistence line in $P - T$ plane. We set $q = \alpha = 1$.

VI. JOULE-THOMSON EXPANSION OF ADS BLACK HOLE WITH NED

In this section, we investigate the Joule-Thomson expansion of novel AdS-NED black hole, where occurs when a flowing gas passes through a pressure regulator, which acts as a throttling porous plug. To balance out any Joule-Thomson related temperature changes, a heating or cooling process on novel AdS-NED black hole can be thought. Joule-Thomson expansion needs a constant enthalpy or black hole mass in extended phase space, in other words, it is called an isenthalpic. The Joule-Thomson coefficient is defined as \[85\]

$$\mu_J = \left. \frac{\partial T}{\partial P} \right|_M = \frac{1}{C_P} \left[ T \left( \frac{\partial V}{\partial T} \right)_P - V \right]. \quad (56)$$
FIG. 5: The isenthalpy process in P-T graph with fixed $M = 15, 18, 20, 22$ from bottom to top (black lines). We set $q = 10$ and $\alpha = 1$. The red points in each process denote the transition points of the cooling and heating regions for the related $M$, satisfying $\mu_J = 0$. The blue line is $P_i - T_i$ border.

FIG. 6: Inversion curves $P_i - T_i$ for heating process and cooling for different charges. We set $\alpha = 1$.

In order to study the Joule-Thomson expansion, we rewrite the pressure $P$ as a function of the mass of black hole $M$ and the event horizon $r_h$ as

$$P(M, r_h) = \frac{6\alpha^4 M - 2\sqrt{2}\alpha^2 q r_h - 3\alpha^4 r_h - 4\sqrt{2}\alpha^3 q^{3/2} \arctanh \left( \frac{\alpha \sqrt{2}}{\alpha \sqrt{2}} \right) - 4r_h^3 \ln \left( 1 - \frac{\alpha^2}{\sqrt{2}r_h} \right)}{8\pi \alpha^4 r_h^3}, \quad (57)$$

and the temperature is

$$T(M, r_h) = \frac{\alpha (3M - r_h) - 2\sqrt{2}\alpha^{3/2} \arctanh \left( \frac{\alpha \sqrt{2}}{\alpha \sqrt{2}} \right)}{2\pi \alpha r_h^2}. \quad (58)$$

From the above equation, we can cancel the event horizon and write $T$ as a function of $(M, P)$ which is analytical difficulty. However, we numerically show the isenthalpy process with fixed $M = 15, 18, 20, 22$ from bottom to top in figure 5 where we set $q = 10$ and $\alpha = 1$. The red points in each process denote kind of inversion point satisfying $\mu_J = 0$ we will interpret soon.

Then, we will study the properties of the inverse points with the use of the Joule-Thomson coefficient

$$\mu_J = \left( \frac{\partial T}{\partial P} \right)_M = \frac{\left( \frac{\partial T(r_h, M)}{\partial r_h} \right)_M}{\left( \frac{\partial P(r_h, M)}{\partial r_h} \right)_M} = \frac{2r_h \left( 2\alpha r_h \left( r_h - 6M \right) + 2q^2 \right) + \sqrt{2}\alpha^3 q \left( 6M - r_h \right) - 4\sqrt{2}\alpha^{3/2} \left( \sqrt{2}\alpha^2 q - 2r_h^2 \right) \tanh^{-1} \left( \frac{\alpha \sqrt{2}}{\alpha \sqrt{2}} \right)}{3 \left( 2r_h^2 - \sqrt{2}\alpha^2 q \right) \alpha \left( r_h - 3M \right) + 2\sqrt{2}\alpha^{3/2} \tanh^{-1} \left( \frac{\alpha \sqrt{2}}{\alpha \sqrt{2}} \right)}}, \quad (59)$$
and table T

TABLE II: The related quantities for minimal inversion temperature with the change of charge.

FIG. 7: Inversion curves \( P_i - T_i \) for heating process and cooling for different \( \alpha \). We set \( q = 10 \).

For \( \mu_J = 0 \), we obtain the inversion temperature from Eq.(56) as

\[
T_i = V \left( \frac{\partial T}{\partial V} \right)_P = \frac{4 \sqrt{2} q \alpha^2 r_h^2 \left( 1 - 2 \ln \left( 1 - \frac{\alpha^2}{\sqrt{2} r_h} \right) \right) + 8 r_h^5 \ln \left( 1 - \frac{\alpha^2}{\sqrt{2} r_h} \right)}{12 \pi \alpha^4 \left( \sqrt{2} r_h^2 - \alpha^2 q \right)^2} \]

\[
2 \sqrt{2} q \alpha^2 (q^2 - r_h^2) + \alpha^4 q^2 + 8 \pi P r_h^2 (2 \sqrt{2} q r_h^2 \alpha^2 - 2 r_h^4 - q^2 \alpha^4) + 2 r_h^4 - 16 \pi r_h^6 - 8 q^2 r_h^2 \ln \left( 1 - \frac{\alpha^2}{\sqrt{2} r_h} \right)
\]

of which the corresponding pressure is \( P_i \). The relation of \( P_i - T_i \) for \( q = 10 \) and \( \alpha = 1 \) is shown in the blue line in figure 5, which is kind of border. In the left side of the border, the Joule-Thomson coefficient satisfies \( \mu_J > 0 \) which denotes a heating process while in the right side, we have \( \mu_J < 0 \) denoting a cooling process. From the figure, we can also see that both \( T_i \) and \( P_i \) increase as \( M \) and only one branch exists like the observation in the previous literatures[85–89], which is different form the van der Waals fluids.

| \( q \) | \( P_i \) | \( r_h \) | \( M_i \) | \( T_i^{\text{min}} \) | \( T_c \) | \( T_i^{\text{min}} / T_c \) (error) |
|---|---|---|---|---|---|---|
| 5  | 6.3762 | 5.1880 | 0.004330 | 0.008564 | 1/2(1.13%) |
| 8  | 10.0520 | 8.2501 | 0.002707 | 0.005375 | 1/2(0.72%) |
| 10 | 12.5019 | 10.2915 | 0.002166 | 0.004306 | 1/2(0.59%) |

TABLE I: The related quantities for minimal inversion temperature with the change of charge. \( \alpha \) is set to be 1.

| \( \alpha \) | \( P_i \) | \( r_h \) | \( M_i \) | \( T_i^{\text{min}} \) | \( T_c \) | \( T_i^{\text{min}} / T_c \) (error) |
|---|---|---|---|---|---|---|
| 1  | 12.5019 | 10.2915 | 0.002166 | 0.004306 | 1/2(0.59%) |
| 2  | 13.2422 | 10.5431 | 0.002163 | 0.004234 | 1/2(2.15%) |
| 3  | 14.1070 | 10.9504 | 0.002152 | 0.004125 | 1/2(4.35%) |

TABLE II: The related quantities for minimal inversion temperature with the change of charge. \( q \) is set to be 10.

Furthermore, we show the inversion curve \( P_i - T_i \) with different parameters in NED black hole in figure 6 and 7. In figure 6, as the charge increases, the inversion point is bigger and the curve is higher, which is consistent with that in RN case. Similar effect of \( \alpha \) also can be seen in figure 7 which means the NED enhances the effect of the charge. In all cases, \( T_i \) increases as \( P_i \), so that the minimum inversion temperature \( T_i^{\text{min}} \) occurs at \( P_i = 0 \). We list the related quantities in table I and table II with samples of \( q \) and \( \alpha \), respectively. Our numerical calculations show \( T_i^{\text{min}} / T_c \sim 1/2 \) with ignorable errors. This result is somehow consistent with the exact 1/2 found by Ökcü and Aydıner [85].

VII. CONCLUSION AND DISCUSSION

In this paper, we have constructed a new AdS black hole solution using the nonlinear electrodynamics. To do so, we have introduced a new model of NED Lagrangian which is converted to Maxwell’s electrodynamics in weak field limit for \( \alpha \to 0 \), and solved the corresponding energy-momentum tensor within the Einstein’s field equations to find new AdS black hole solution in four dimensions.
We have studied the thermal stability of the novel AdS-NED black hole. First we have used the complex path (or Hamilton-Jacobi) approach to find the hawking radiation by the tunneling massive vector particles from the novel AdS-NED black hole. Next, we have studied the thermodynamic properties of the novel AdS-NED black hole on usual phase space, where we show that the first law of thermodynamics is satisfied and the heat capacity is obtained as positive which is mandatory for stability of the black hole. Afterwards we have presented the thermodynamical properties of the novel AdS-NED black hole in the extended phase space by defining the cosmological constant as the pressure with calculating the extended first law of the thermodynamics and the generalized Smarr relation of the novel AdS-NED black hole.

We have also investigated the $P-V$ criticality. The $P-V$ diagram is similar to the Van der Waals fluid with fixed $q$ and $\alpha$. The critical point was analytically obtained which show that the critical horizon increases as both $q$ and $\alpha$ while the critical temperature and pressure have totally opposite tendency. We also figure out the coexistence line in $(P,T)$-plane with $\alpha = q = 1$ by calculating the Helmholtz free energy with fixed charged ensemble. In the left region of the coexistence line the small black hole is physically flavor while the large black hole is stable below the line.

Lastly, JT expansion of novel AdS-NED black hole have been studied. The curve of $P_2-T_1$ with vanishing Joule-Thomson coefficient was carefully analyzed. In the left side of the curve, we have $\mu_J > 0$ which denotes a heating process while in the right side, we have $\mu_J < 0$ denoting a cooling process. Furthermore, the effect of parameters in NED black hole on the inversion curve was studied. And we found the NED promote the effect of the charge, which enhances the inversion points. Similar to the previous studies [85–89], the curve only presents one branch which is different form the van der Waals fluids. Finally, we studied the ratio $T_i^{\text{min}}/T_c$ which in around 1/2 with tiny numerical errors. Our result is somehow consistent with the exact 1/2 found by Ökcü and Aydmer [85]. In our model, the study of JT expansion mainly done by numeric and the exact analytic is called for.
